The NAND flash controller supports up to four outstanding DMA commands, and ignores additional DMA commands. If software issues more than four outstanding DMA commands, the flash controller issues the `unsup_cmd` interrupt. On receipt of a DMA command, the flash controller performs command sequencing to transfer the number of pages requested in the DMA command. The DMA master reads or writes page data from the system memory in programmed burst-length chunks. After the DMA command completes, the flash controller issues an interrupt, and starts working on the next queued DMA command.

Pipelining allows the NAND flash controller to optimize its performance while executing back-to-back commands of the same type.

With certain restrictions, non-DMA MAP10 commands can be issued to the NAND flash controller while the flash controller is servicing DMA transactions. MAP00, MAP01, and MAP11 commands cannot be issued while DMA mode is enabled because the flash controller is operating in an extremely tightly-coupled, high-performance data transfer mode. On receipt of erroneous commands (MAP00, MAP01 or MAP11), the flash controller issues an `unsup_cmd` interrupt to inform the host about the violating command.

Consider the following points when using the DMA:

- A data DMA command is a type of MAP10 command. This command is interpreted by the data DMA engine and not by the flash controller core.
- No MAP01, MAP00, or MAP11 commands are allowed when DMA is enabled.
- Before the flash controller can accept data DMA commands, DMA must be enabled by setting the `flag` bit of the `dma_enable` register in the `dma` group.
- When DMA is enabled and the DMA engine initiates data transfers, ECC can be enabled for as-needed data correction concurrent with the data transfer.
- MAP10 commands are used along with data movements similar to MAP01 commands.
- With the exception of data DMA commands and MAP10 pipeline read and write commands, all other MAP10 commands such as erase, lock, unlock, and copy-back are forwarded to the flash controller.
- At any time, up to four outstanding data DMA commands can be handled by flash controller. During multi-page operations, the DMA transfer must not cross a flash block boundary. If it does, the flash controller generates an unsupported command (`unsup_cmd`) interrupt and drops the command.
- Data DMA commands are typically multi-page read and write commands with an associated pointer in host memory. The multi-page data is transferred to or from the host memory starting from the host memory pointer.
- Data DMA uses the `flash_burst_length` register in the `dma` group to determine the burst length value to drive on the interconnect. The data DMA hardware does not account for the interconnect's boundary crossing restrictions. The host must initialize the starting host address so that the DMA master burst does not cross a 4 KB boundary.

There are two methods for initiating a DMA transaction: the multitransaction DMA command, and the burst DMA command.

Multi-transaction DMA Command

The NAND flash controller processes multitransaction DMA commands only if it receives all four command-data pairs in order. The flash controller responds to out-of-order commands with an `unsup_cmd` interrupt. The flash controller also responds with an `unsup_cmd` interrupt if sequenced commands are interleaved with other flash controller MAP commands.

To initiate DMA with a multitransaction DMA command, you send four command-data pairs to the NAND flash controller's data and control slave port, as shown in *Command-Data Pair Formats*.

Related Information

Command-Data Pair Formats on page 13-14

Command-Data Pair Formats

Table 13-10: Command-Data Pair 1

	31:28	27:26	25:24	23:<*M*>	(<*M*> – 1):0
Command	0x0	0x2	0x0	Block address	Page address

	31:16	15:12	11:8	7:0
Data	0x0	0x2	0x0 = Read 0x1 = Write	<*PP*>= Number of pages

Table 13-11: Command-Data Pair 2

	31:28	27:26	25:24	23:8	7:0
Command	0x0	0x2	0x0	Memory address high[30]	0x0

	31:16	15:12	11:8	7:0
Data	0x0	0x2	0x2	0x0

Table 13-12: Command-Data Pair 3

	31:28	27:26	25:24	23:8	7:0
Command	0x0	0x2	0x0	Memory address low[31]	0x0

	31:16	15:12	11:8	7:0
Data	0x0	0x2	0x3	0x0

(29) <*M*> depends on the number of pages per block in the device. <*M*> = ceil(log2(<*device pages per block*>)). Therefore, use the following values:

32 pages per block: <*M*>=5

64 pages per block: <*M*>=6

128 pages per block: <*M*>=7

256 pages per block: <*M*>=8

384 pages per block: <*M*>=9

512 pages per block: <*M*>=9

(30) The buffer address in host memory, which must be aligned to 32 bits.

(31) The buffer address in host memory, which must be aligned to 32 bits.

Using Multitransaction DMA Commands

If you want the NAND flash controller DMA to perform cacheable accesses then you must configure the cache bits by writing the `l3master` register in the `nandgrp` group in the system manager. The NAND flash controller DMA must be idle before you use the system manager to change its cache capabilities.

You can issue non-DMA MAP10 commands while the NAND flash controller is in DMA mode. For example, you might trigger a host-initiated page move between DMA commands, to achieve wear leveling. However, do not interleave non-DMA MAP10 commands between the command-data pairs in a set of multitransaction DMA commands. You must issue all four command-data pairs shown in the above tables before sending a different command.

Note: Do not issue MAP00, MAP01 or MAP11 commands while DMA is enabled.

MAP10 commands in multitransaction format are written to the `Data` register at offset 0x10 in `nanddata`, the same as MAP10 commands in increment four (INCR4) format (described in *Burst DMA Command*).

Related Information

- **Indexed Addressing** on page 13-6
- **Burst DMA Command** on page 13-15
- **System Manager** on page 5-1

Burst DMA Command

You can initiate a DMA transfer by sending a command to the NAND flash controller as a burst transaction of four 16-bit accesses. This form of DMA command might be useful for initiating DMA transfers from custom IP in the FPGA fabric. Most processor cores cannot use this form of DMA command, because they cannot control the width of the burst.

When DMA is enabled, the NAND flash controller recognizes the MAP10 pipeline DMA command as an INCR4 command, in the format shown in the following table. The address decoding for MAP10 pipeline DMA command remains the same, as shown in *MAP10 Address Mapping*.

(32) INT specifies the host interrupt to be generated at the end of the complete DMA transfer. INT controls the value of the `dma_cmd_comp` bit of the `intr_status0` register in the `status` group at the end of the DMA transfer. INT can take on one of the following values:

0—Do not interrupt host. The `dma_cmd_comp` bit is set to 0.

1—Interrupt host. The `dma_cmd_comp` bit is set to 1.

MAP10 commands in INCR4 format are written to the `Data` register at offset 0x10 in `nanddata`, the same as MAP10 commands in multitransaction format (described in *Multitransaction DMA Command*).

Table 13-14: MAP10 Burst DMA (INCR4) Command Structure

The following table lists the MAP10 burst DMA command structure. The burst DMA command carries the same information as the multi-transaction DMA command-data pairs, but in a very different format.

Data Beat	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Beat 0	0x2				0x0: read. 0x1: write.				<*PP*>=number of pages							
Beat 1 (33)	Memory address high															
Beat 2 (33)	Memory address low															
Beat 3	0x0							INT (34)	Burst length							

You can optionally send the 16-bit fields in the above table to the NAND flash controller as four separate bursts of length 1 in sequential order. Altera recommends this method.

If you want the NAND flash controller DMA to perform cacheable accesses, you must configure the cache bits by writing the `l3master` register in the `nandgrp` group in the system manager. The NAND flash controller DMA must be idle before you use the system manager to modify its cache capabilities.

ECC

The NAND flash controller incorporates ECC logic to calculate and correct bit errors. The flash controller uses a Bose-Chaudhuri-Hocquenghem (BCH) algorithm for detection of multiple errors in a page.

The NAND flash controller supports 512- and 1024-byte ECC sectors. The flash controller inserts ECC check bits for every 512 or 1024 bytes of data, depending on the selected sector size. After 512 or 1024 bytes, the flash controller writes the ECC check bit information to the device page.

ECC information is striped in between 512 or 1024 bytes of data across the page. The NAND flash controller reads ECC information in the same pattern and the presence of errors is calculated according to 512 or 1024 bytes of data read.

(33) The buffer address in host memory, which must be aligned to 32 bits

(34) INT specifies the host interrupt to be generated at the end of the complete DMA transfer. INT controls the value of the `dma_cmd_comp` bit of the `intr_status0` register in the `status` group at the end of the DMA transfer. INT can take on one of the following values:

0—Do not interrupt host. The `dma_cmd_comp` bit is set to 0.

1—Interrupt host. The `dma_cmd_com p` bit is set to 1.

Correction Capability, Sector Size, and Check Bit Size

Table 13-15: Correction Capability, Sector Size, and Check Bit Size

Correction	Sector Size in Bytes	Check Bit Size in Bytes
4	512	8
8	512	14
16	512	26
24	1024	46

ECC Programming Modes

The NAND flash controller provides the following ECC programming modes that software uses to format a page:

- Main Area Transfer Mode
- Spare Area Transfer Mode
- Main+Spare Area Transfer Mode

Related Information

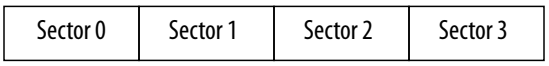
- **Main Area Transfer Mode** on page 13-17
- **Spare Area Transfer Mode** on page 13-17
- **Main+Spare Area Transfer Mode** on page 13-18

Main Area Transfer Mode

In main area transfer mode, when ECC is enabled, the NAND flash controller inserts ECC check bits in the data stream on writes and strips ECC check bits on reads. Software does not need to manage the ECC sectors when writing a page. ECC checking is performed by the flash controller, so software simply transfers the data.

If ECC is turned off, the NAND flash controller does not read or write ECC check bits.

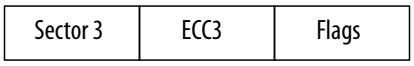
Figure 13-2: Main Area Transfer Mode Programming Model for ECC



Spare Area Transfer Mode

The NAND flash controller does not introduce or interpret ECC check bits in spare area transfer mode, and acts as a pass-through for data transfer.

Figure 13-3: Spare Area Transfer Mode Programming Model for ECC



Main+Spare Area Transfer Mode

In main+spare area transfer mode, the NAND flash controller expects software to format a page as shown in following figure. When ECC is enabled during a write operation, the flash controller-generated ECC check bits replace the ECC check bit data provided by software. During read operations, the flash controller forwards the ECC check bits from the device to the host. If ECC is disabled, page data received from the software is written to the device, and read data received from the device is forwarded to the host.

Figure 13-4: Main+Spare Area Transfer Mode Programming Model for ECC

Preserving Bad Block Markers

When flash device manufacturers test their devices at the time of manufacture, they mark any bad device blocks that are found. Each bad block is marked at specific, known offsets, typically at the base of the spare area. A bad block marker is any byte value other than 0xFF (the normal state of erased flash).

Bad block markers can be overwritten by the last sector data in a page when ECC is enabled. This happens because the NAND flash controller also uses the main area of a page to store ECC information, which causes the last sector to spill over into the spare area. It is necessary for the system to preserve the bad block information prior to writing data, to ensure the correct identification of bad blocks in the flash device.

You can configure the NAND flash controller to skip over a specified number of bytes when it writes the last sector in a page to the spare area. This option allows the flash controller to preserve bad block markers. To use this option, write the desired offset to the `spare_area_skip_bytes` register in the `config` group. For example, if the device page size is 2 KB, and the device manufacturer stores the bad block markers in the first two bytes in the spare area, set the `spare_area_skip_bytes` register to 2. When the flash controller writes the last sector of the page that overlaps with the spare area, it starts at offset 2 in the spare area, skipping the bad block marker at offset 0. A value of 0 (default) specifies that no bytes are skipped. The value of `spare_area_skip_bytes` must be an even number. For example, if the bad block marker is a single byte, set `spare_area_skip_bytes` to 2.

In main area transfer mode, the NAND flash controller does not skip the bad block marker. Instead, it overrides the bad block marker with the value programmed in the `spare_area_marker` register in the `config` group. This 8-bit register is used in conjunction with the `spare_area_skip_bytes` register in the `config` group to determine which bytes in the spare area of a page should be written with a the new marker value. For example, to mark a block as good set the `spare_area_marker` register to 0xFF and set the `spare_area_skip_bytes` register to the number of bytes that the marker should be written to, starting from the base of the spare area.

In the spare area transfer mode, the NAND flash controller ignores the `spare_area_skip_bytes` and `spare_area_marker` registers. The flash controller transfers the data exactly as received from the host or device.

In the main+spare area transfer mode, the NAND flash controller starts writing the last sector in a page into the spare area, starting at the offset specified in the `spare_area_skip_bytes` register. However, the area containing the bad block identifier information is overwritten by the data the host writes into the page. The host writes both the data sectors and the bad block markers. The flash controller depends on the host software to set up the bad block markers properly before writing the data.

Figure 13-5: Bad Block Marker

The following figure shows an example of how the NAND flash controller can skip over a bad block marker. In this example, the flash device has a 2-KB page with a 64-byte spare area. A 14-byte sector ECC is shown, with 8 byte per sector correction.

Transfer Mode Operations on page 13-25
For detailed information about configuring the NAND flash controller for default, spare, or main+spare area transfer mode.

Error Correction Status

The ECC error correction information (`ECCCorInfo_b01`) register, in the `ecc` group, contains error correction information for each read or write that the NAND flash controller performs. The `ECCCorInfo_b01` register contains ECC error correction information in the `max_errors_b0` and `uncor_err_b0` fields.

At the end of data correction for the transaction in progress, `ECCCorInfo_b01` holds the maximum number of corrections applied to any ECC sector in the transaction. In addition, this register indicates whether the transaction as a whole has correctable errors, uncorrectable errors, or no errors at all. A transaction has no errors when none of the ECC sectors in the transaction has any errors. The transaction is marked as uncorrectable if any one of the sectors is uncorrectable. The transaction is marked as correctable if any one sector has correctable errors and none is uncorrectable.

At the end of each transaction, the host must read this register. The value of this register provides data to the host about the block. The host can take corrective action after the number of correctable errors encountered reaches a particular threshold value.

Interface Signals

Table 13-16: NAND Flash Interface Signals

As listed in the following table, the HPS I/O pins support a single x8 device.

Signal	Width	I/O	Description
`ad`	8	in/out	Command, address and data for the flash device
`ale`	1	out	Address latch enable

Signal	Width	I/O	Description
ce_n	1	out	Output Active-low chip enable
cle	1	out	Command latch enable
re_n	1	out	Active-low read enable signal
rb	1	in	Ready/busy signal
we_n	1	out	Active-low write enable signal
wp_n	1	out	Active-low write protect signal

NAND Flash Controller Programming Model

This section describes how the NAND flash controller is to be programmed by software running on the microprocessor unit (MPU).

Note: If you write a configuration register and follow it up with a data operation that is dependent on the value of this configuration register, Altera recommends that you read the value of the register before performing the data operation. This read operation ensures that the posted write of the register is completed and takes effect before the data operation is issued to the NAND flash controller.

Basic Flash Programming

This section describes the steps that must be taken by the software to access and control the NAND flash controller.

NAND Flash Controller Optimization Sequence

The software must configure the flash device for interrupt or polling mode, using the `bank0` bit of the `rb_pin_enabled` register in the `config` group. If the device is in polling mode, the software must also program the additional registers, to select the times and frequencies of the polling. Program the following registers in the `config` group:

- Set the `rb_pin_enabled` register to the desired mode of operation for each flash device.
- For polling mode, set the `load_wait_cnt` register to the appropriate value depending on the speed of operation of the NAND flash controller, and the desired wait value.
- For polling mode, set the `program_wait_cnt` register to the appropriate value by software depending on the speed of operation of the NAND flash controller, and the desired wait value.
- For polling mode, set the `erase_wait_cnt` register to the appropriate value by software depending on the speed of operation of the NAND flash controller, and the desired wait value.
- For polling mode, set the `int_mon_cyccnt` register to the appropriate value by software depending on the speed of operation of the NAND flash controller, and the desired wait value.

At any time, the software can change any flash device from interrupt mode to polling mode or vice-versa, using the `bank0` bit of the `rb_pin_enabled` register.

The software must ensure that the particular flash device does not have any outstanding transactions before changing the mode of operation for that particular flash device.

Device Initialization Sequence

At initialization, the host software must program the following registers in the `config` group:

- Set the `devices_connected` register to 1.
- Set the `device_width` register to 8.
- Set the `device_main_area_size` register to the appropriate value.
- Set the `device_spare_area_size` register to the appropriate value.
- Set the `pages_per_block` register according to the parameters of the flash device.
- Set the `number_of_planes` register according to the parameters of the flash device.
- If the device allows two ROW address cycles, the `flag` bit of the `two_row_addr_cycles` register must be set to 1. The host program can ensure this condition either of the following ways:
  - Set the `flag` bit of the `bootstrap_two_row_addr_cycles` register to 1 prior to the NAND flash controller's reset initialization sequence, causing the flash controller to initialize the bit automatically.
  - Set the `flag` bit of the `two_row_addr_cycles` register directly to 1.
- Clear the `chip_enable_dont_care` register in the `config` group to 0.

The NAND flash controller can identify the flash device features, allowing you to initialize the flash controller registers to interface correctly with the device, as described in *Discovery and Initialization*.

However, a few NAND devices do not follow any universally accepted identification protocol. If connected to such a device, the NAND flash controller cannot identify it correctly. If you are using such a device, your software must use other means to ensure that the initialization registers are set up correctly.

Related Information

Discovery and Initialization on page 13-3

Device Operation Control

This section provides a list of registers that you need to program while choosing to use multi-plane or cache operations on the device. If the device does not support multi-plane operations or cache operations, then these registers can be left at their power-on reset values with no impact on the functionality of the NAND flash controller. Even if the device supports these sequences, the software may choose not to use these sequences and can leave these registers at their power-on reset values.

Program the following registers in the `config` group to achieve the best performance from a given device:

- Set `flag` bit in the `multiplane_operation` register in the `config` group to 1 if the device supports multi-plane operations to access the data on the flash device connected to the NAND flash controller. If the flash controller is set up for multi-plane operations, the number of pages to be accessed is always a multiple of the number of planes in the device.
- If the NAND flash controller is configured for multi-plane operation, and if the device has support for multi-plane read command sequence, set the `multiplane_read_enable` register in the `config` group.
- If the device implements multiplane address restrictions, set the `flag` bit in the `multiplane_addr_restrict` register to 1.
- Initialize the `die_mask` and `first_block_of_next_plane` registers as per device requirements.

- If the device supports cache command sequences, enable the `cache_write_enable` and `cache_read_enable` registers in the `config` group.
- Clear the `flag` bit of the `copyback_disable` register in the `config` group to 0 if the device does not support the copyback command sequences. The register defaults to enabled state.
- The `read_mode`, `write_mode` and `copyback_mode` registers, in the `config` group, currently need not be written by software, because the NAND flash controller is capable of using the correct sequences based on a combination of some multi-plane or cache-related settings of the NAND flash controller and the manufacturer ID. If at some future time these settings change, program the registers to accommodate the change.

ECC Enabling

Before you start any data operation on the flash device, you must decide whether you want the ECC enabled or disabled.

If the ECC needs enabling, set up the appropriate correction level depending on the page size and the spare area available on the device.

Set the `flag` bit in the `ecc_enable` register in the `config` group to 1 to enable ECC. If enabled, the following registers in the `config` group must be programmed accordingly, else they can be ignored:

- Initialize the `ecc_correction` register to the appropriate correction level.
- Program the `spare_area_skip_bytes` and `spare_area_marker` registers in the `config` group if the software needs to preserve the bad block marker.

Related Information

ECC on page 13-16

NAND Flash Controller Performance Registers

These registers specify the size of the bursts on the device interface, which maximizes the overall performance on the NAND flash controller.

Initialize the `flash_burst_length` register in the `dma` group to a value which maximizes the performance of the device interface by minimizing the number of bursts required to transfer a page.

Interrupt and DMA Enabling

Prior to initiating any data operation on the NAND flash controller, the software must set appropriate interrupt status register bits. If the software chooses to use the DMA logic in the flash controller, then the appropriate DMA enable and interrupts bits in the register space must be set.

1. Set the `flag` bit in the `global_int_enable` register in the `config` group to 1, to enable global interrupt.
2. Set the relevant bits of the `intr_en0` register in the `status` group to 1 before sending any operations if the flash controller is in interrupt mode.
3. Enable DMA if your application needs DMA mode. Enable DMA by setting the `flag` bit of the `dma_enable` register in the `dma` group. Altera recommends that the software reads back this register to ensure that the mode change is accepted before sending a DMA command to the flash controller.
4. If the DMA is enabled, then set up the appropriate bits of the `dma_intr_en` register in the `dma` group.

Order of Interrupt Status Bits Assertion

The following interrupt status bits, in the `intr_status0` register in the `status` group, are listed in the order of interrupt bit setting:

1. time_out—All other interrupt bits are set to 0 when the watchdog time_out bit is asserted.
2. dma_cmd_comp—This interrupt status bit is the last to be asserted during a DMA operation to transfer data. This bit signifies the completion of data transfer sequence.
3. pipe_cpybck_cmd_comp—This bit is asserted when a copyback command or the last page of a pipeline command completes.
4. locked_blk—This bit is asserted when a program (or erase) is performed on a locked block.
5. INT_act—No relationship with other interrupt status bits. Indicates a transition from 0 to 1 on the ready_busy pin value for that flash device.
6. rst_comp—No relationship with other interrupt status bits. Occurs after a reset command has completed.
7. For an erase command:
   a. erase_fail (if failure)
   b. erase_comp
8. For a program command:
   a. locked_blk (if performed on a locked block)
   b. pipe_cmd_err (if the pipeline sequence is broken by a MAP01 command)
   c. page_xfer_inc (at the end of each page data transfer)
   d. program_fail (if failure)
   e. pipe_cpybck_cmd_comp
   f. program_comp
   g. dma_cmd_comp (If DMA enabled)
9. For a read command:
   a. pipe_cmd_err (if the pipeline sequence is broken by a MAP01 command)
   b. page_xfer_inc (at the end of each page data transfer)
   c. pipe_cpybck_cmd_comp
   d. load_comp
   e. ecc_uncor_error (if failure)
   f. dma_cmd_comp (If DMA enabled)

Timing Registers

You must optimize the following registers for your flash device's speed grade and clock frequency. The NAND flash controller operates correctly with the power-on reset values. However, functioning with power-on reset values is a non-optimal mode that provides loose timing (large margins to the signals).

Set the following registers in the config group to optimize the NAND flash controller for the speed grade of the connected device and frequency of operation of the flash controller:

- twhr2_and_we_2_re
- tcwaw_and_addr_2_data
- re_2_we
- acc_clks
- rdwr_en_lo_cnt
- rdwr_en_hi_cnt
- max_rd_delay
- cs_setup_cnt
- re_2_re

Registers to Ignore

You do not need to initialize the following registers in the `config` group:

- The `transfer_spare_reg` register—Data transfer mode can be initialized using MAP10 commands.
- The `write_protect` register—Does not need initializing unless you are testing the write protection feature.

Flash-Related Special Function Operations

This section describes all the special functions that can be performed on the flash memory.

The functions are defined by MAP10 commands as described in *Command Mapping*.

Related Information

Command Mapping on page 13-7

Erase Operations

Before data can be written to flash, an erase cycle must occur. The NAND flash memory controller supports single block and multi-plane erases.

The controller decodes the block address from the indirect addressing shown in *MAP10 Address Mapping*.

Related Information

MAP10 Address Mapping on page 13-10

Single Block Erase

A single command is needed to complete a single-block erase, as follows:

1. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the desired erase block.
2. Write 0x01 to the `Data` register.

For a single block erase, the register `multiplane_operation` in the `config` group must be reset.

After device completes erase operation, the controller generates an `erase_comp` interrupt. If the erase operation fails, the `erase_fail` interrupt is issued. The failing block's address is updated in the `err_block_addr0` register in the `status` group.

Multi-Plane Erase

For multi-plane erases, the `number_of_planes` register in the `config` group holds the number of planes in the flash device, and the block address specified must be aligned to the number of planes in the device. The NAND flash controller consecutively erases each block of the memory, up to the number of planes available. Issue this command as follows:

1. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the desired erase block.
2. Write 0x01 to the `Data` register.

For multi-plane erase, the register `multiplane_operation` in the `config` group must be set.

After the device completes erase operation on all planes, the NAND flash controller generates an `erase_comp` interrupt. If the erase operation fails on any of the blocks in a multi-plane erase command, an `erase_fail` interrupt is issued. The failing block's address is updated in the `err_block_addr0` register in the `status` group.

Lock Operations

The NAND flash controller supports the following features:

- Flash locking—The NAND flash controller supports all flash locking operations.

  The flash device itself might have limited support for these functions. If the device does not support locking functions, the flash controller ignores these commands.
- Lock-tight—With the lock-tight feature, the NAND flash controller can prevent lock status from being changed. After the memory is locked tight, the flash controller must be reset before any flash area can be locked or unlocked.

Unlocking a Span of Memory Blocks

To unlock several blocks of memory, perform the following steps:

1. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the starting address of the area to unlock.
2. Write 0x10 to the `Data` register.
3. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the ending address of the area to unlock.
4. Write 0x11 to the `Data` register.

When unlocking a range of blocks, the start block address must be less than the end block address. Otherwise, the NAND flash controller exhibits undetermined behavior.

Locking All Memory Blocks

To lock the entire memory:

1. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to any memory address.
2. Write 0x21 to the `Data` register.

Setting Lock-Tight on All Memory Blocks

After the lock-tight is applied, unlocked areas cannot be locked, and locked areas cannot be unlocked. To lock-tight the entire memory:

1. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to any memory address.
2. Write 0x31 to the `Data` register.

To disable the lock-tight, reset the memory controller.

Transfer Mode Operations

You can configure the NAND flash controller in one of the following modes of data transfer:

- Default area transfer mode
- Spare area transfer mode
- Main+spare area transfer mode

The NAND flash controller determines the default transfer mode from the setting of `transfer_spare_reg` register in the `config` group. Use MAP10 commands to dynamically change the transfer mode from the existing mode to the new mode. All subsequent commands are in the new mode

of transfer. You must consider that transfer modes can be changed at logical data transfer boundaries. For example:

- At the beginning or end of a page in case of single page read or write.
- At the beginning or end of a complete multi-page pipeline read or write command.

transfer_spare_reg and MAP10 Transfer Mode Commands

The following table lists the functionality of the MAP10 transfer mode commands, and their mappings to the `transfer_spare_reg` register in the `config` group.

Table 13-17: transfer_spare_reg and MAP10 Transfer Mode Commands

transfer_spare_reg	MAP10 Transfer Mode Commands	Resulting NAND Flash Controller Mode
0	0x42	Main(35)
0	0x41	Spare
0	0x43	Main+spare
1	0x42	Main+spare(35)
1	0x41	Spare
1	0x43	Main+spare

Related Information

MAP10 Commands on page 13-9

Configure for Default Area Access

You only need to configure for default area access if the transfer mode was previously changed to spare area or main+spare area. To configure default area access:

1. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to any block.
2. Write 0x42 to the `Data` register.

The NAND flash controller determines the default area transfer mode from the setting of the `transfer_spare_reg` register in the `config` group. If it is set to 1, then the transfer mode becomes main +spare area, otherwise it is main area.

Configure for Spare Area Access

To access only the spare area of the flash device, use the MAP10 command to set up the NAND flash controller to read or write only the spare area on the device. After the flash controller is set up, use MAP01 read and write commands to access the spare area of the appropriate block and page addresses. To configure the NAND flash controller to access the spare area only, perform the following steps:

(35) Default access mode (0x42) maps to either main (only) or main+spare mode, depending on the value of `transfer_spare_reg`.

1. Write to the command register, setting the CMD_MAP field to 2 and the BLK_ADDR field to the target block.
2. Write 0x41 to the Data register.

Configure for Main+Spare Area Access

To configure the NAND flash controller to access the main+spare area:

1. Write to the command register, setting the CMD_MAP field to 2 and the BLK_ ADDR field to the target block.
2. Write 0x43 to the Data register.

Read-Modify-Write Operations

To read a specific page or modify a few words, bytes, or bits in a page, use the RMW operations. A read command copies the desired data from flash memory to a page buffer. You can then modify the information in the buffer using MAP00 buffer read and write commands and issue another command to write that information back to the memory.

The read-modify-write command operates on an entire page. This command is also useful for a copy type operation, where most of a page is saved to a new location. In this type of operation, the NAND flash controller reads the data, modifies a specified number of words in the page, and then writes the modified page to a new location.

Note: Because the data is modified within the page buffer of the flash device, the NAND flash controller ECC hardware is not used in RMW operations. Software must update the ECC during RMW operations.

Note: For a read-modify-write command to work with hardware ECC, the entire page must be read into system memory, modified, then written back to flash without relying on the RMW feature.

Read-Modify-Write Operation Flow

1. Start the flow by reading a page from the memory:
   - Write to the command register, setting the CMD_MAP field to 2 and the BLK_ADDR field to the starting address of the desired block.
   - Write 0x60 to the Data register.

   This step makes the page available to you in the page buffer in the flash device.
2. Provide the destination page address:
   - Write to the command register, setting the CMD_MAP field to 2 and the BLK_ADDR field to the destination address of the desired block.
   - Write 0x61 to the Data register.

   This step initiates the page program and provides the destination address to the device.
3. Use the MAP00 page buffer read and write commands to modify the data in the page buffer.
4. Write the page buffer data back to memory:
   - Write to the command register, setting the CMD_MAP field to 2 and the BLK_ADDR field to the same destination address.
   - Write 0x62 to the Data register.

   This step performs the write.

After the device completes the load operation, the NAND flash controller issues a `load_comp` interrupt. A `program_comp` interrupt is issued when the host issues the write command and the device completes the program operation.

If the page program operation (as a part of an RMW operation) results in a program failure in the device, `program_fail` interrupt is issued. The failing page's block and page address is updated in the `err_block_addr0` and `err_page_addr0` registers in the `status` group.

Copy-back Operations

The NAND flash controller supports copy back operations. However, the flash device might have limited support for this function. If you attempt to perform a copy-back operation on a device that does not support copy-back, the NAND flash controller triggers an interrupt. An interrupt is also triggered if the source block is not specified before the destination block is specified, or if the destination block is not specified in the next command following a source block specification.

The NAND flash controller cannot do ECC validation in case of copy-back commands. The flash controller copies the ECC data, but does not check it during the copy operation.

Note: Altera recommends that you use copy-back only if the ECC implemented in the flash controller is strong enough so that the next access can correct accumulated errors.

The 8-bit value <*PP*> specifies the number of pages for copy-back. With this feature, the NAND flash controller can copy multiple consecutive pages with a single command. When you issue a copy-back command, the flash controller performs the operation in the background. The flash controller puts other commands on hold until the current copy-back completes.

For a multi-plane device, if the `flag` bit in the `multiplane_operation` register in the `config` group is set to 1, multi-plane copy-back is available as an option. In this case, the block address specified must be plane-aligned and the value <*PP*> must specify the total number of pages to copy as a multiple of the number of planes. The block address continues incrementing, keeping the page address fixed, for the total number of planes in the device before incrementing the page address.

A `pipe_cpyba ck_cmd_comp` interrupt is generated when the flash controller has completed copy-back operation of all <*PP*> pages. If any page program operation (as a part of copy back operation) results in a program failure in the device, the `program_fail` interrupt is issued. The failing page's block and page address is updated in the `err_block_addr0` and `err_page_addr0` registers in the `status` group.

Copying a Memory Area (Single Plane)

To copy <*PP*> pages from one memory location to another:

1. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the starting address of the area to be copied.
2. Write 0x1000 to the `Data` register.
3. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the starting address of the new area to be written.
4. Write 0x11<*PP*> to the `Data` register, where <*PP*> is the number of pages to copy.

Copying a Memory Area (Multi-Plane)

To copy <*PP*> pages from one memory location to another:

1. Set the `flag` bit of the `multiplane_operation` register in the `config` group to 1.
2. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the starting address of the area to be copied. The address must be plane-aligned.
3. Write 0x1000 to the `Data` register.
4. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the starting address of the new area to be written. This address must also be plane-aligned.
5. Write 0x11<*PP*> to the `Data` register, where <*PP*> is the number of pages to copy.

The parameter <*PP*> must be a multiple of the number of planes in the device.

Pipeline Read-Ahead and Write-Ahead Operations

The NAND flash controller supports pipeline read-ahead and write-ahead operations. However, the flash device might have limited support for this function. If the device does not support pipeline read-ahead or write-ahead, the flash controller processes these commands as standard reads or writes.

The NAND flash controller can handle at the most four outstanding pipeline commands, queued up in the order in which the flash controller received the commands. The flash controller operates on the pipeline command at the head of the queue until all the pages corresponding to the pipeline command are executed. The flash controller then pops the pipeline command at the head of the queue and proceeds to work on the next pipeline command in the queue.

The pipeline read-ahead function allows for a continuous reading of the flash memory. On receiving a pipeline read command, the flash controller immediately issues a load command to the device. While data is read out with MAP01 commands in a consecutive or multi-plane address pattern, the flash controller maintains additional cache or multi-plane read command sequencing for continuous streaming of data from the flash device.

The pipeline write-ahead function allows for a continuous writing of the flash memory. While data is written with MAP01 commands in a consecutive or multi-plane address pattern, the NAND flash controller maintains cache or multi-plane command sequences for continuous streaming of data into the flash device.

MAP01 commands must read or write pages in the same sequence that the pipelined commands were issued to the NAND flash controller. If the host issues multiple pipeline commands, pages must be read or written in the order the pipeline commands were issued. It is not possible to read or write pages for a second pipeline command before completing the first pipeline command. If the pipeline sequence is broken by a MAP01 command, the `pipe_cmd_err` interrupt is issued, and the flash controller clears the pipeline command queue. The flash controller services the violating incoming MAP01 read or write request with a normal page read or write sequence.

For a multi-plane device that supports multi-plane programming, you must set the `flag` bit of the `multiplane_operation` register in the `config` group to 1. In this case, the data is interleaved into page-size chunks to consecutive blocks.

Pipeline read-ahead commands can read data from the queue in this interleaved fashion. The parameter <PP> denotes the total number of pages in multiples of the number of planes available, and the block address must be plane-aligned, which keeps the page address constant while incrementing the block address for each page-size chunk of data. After reading from every plane, the NAND flash controller increments the page address and resets the block address to the initial address. You can also use pipeline write-ahead commands in multi-plane mode. The write operation works similarly to the read operation, holding the page address constant while incrementing the block address until all planes are written.

Note: The same four-entry queue is used to queue the address and page count for pipeline read-ahead and write-ahead commands. This commonality requires that you use MAP01 commands to read out all pages for a pipeline read-ahead command before the next pipeline command can be processed. Similarly, you must write to all pages pertaining to pipeline write-ahead command before the next pipeline command can be processed.

Because the value of the `flag` bit of the `multiplane_operation` register in the `config` group determines pipeline read-ahead or write-ahead behavior, it can only be changed when the pipeline registers are empty.

When the host issues a pipeline read-ahead command, and the flash controller is idle, the load operation occurs immediately.

Note: The read-ahead command does not return the data to the host, and the write-ahead command does not write data to the flash address. The NAND flash controller loads the read data. The read data is returned to the host only when the host issues MAP01 commands to read the data. Similarly, the flash controller loads the write data, and writes it to the flash only when the host issues MAP01 commands to write the data.

A `pipe_cpyback_cmd_comp` interrupt is generated when the NAND flash controller has finished processing a pipeline command and has discarded that command from its queue. At this point of time, the host can send another pipeline command. A pipeline command is popped from the queue, and an interrupt is issued when the flash controller has started processing the last page of pipeline command. Hence, the `pipe_cpyback_cmd_comp` interrupt is issued prior to the last page load in the case of a pipeline read command and start of data transfer of the last page to be programmed, in the case of a pipeline write command.

An additional `program_comp` interrupt is generated when the last page program operation completes in the case of a pipeline write command.

If the device command set requires the NAND flash controller to issue a load command for the last page in the pipeline read command, a `load_comp` interrupt is generated after the last page load operation completes.

For pipeline write commands, if any page program results in a failure in the device, a `program_fail` interrupt is issued. The failing page's block and page address is updated in the `err_block_addr0` and `err_page_addr0` registers in the `status` group.

The pipeline commands sequence advanced commands in the device, such as cache and multi-plane. When the NAND flash controller receives a multi-page read or write pipeline command, it sequences commands sent to the device depending on settings in the following registers in the `config` group:

- `cache_read_enable`
- `cache_write_enable`
- `multiplane_operation`

For a device that supports cache read sequences, the `flag` bit of the `cache_read_enable` register must be set to 1. The NAND flash controller sequences each multi-page pipeline read command as a cache read sequence. For a device that supports cache program command sequences, `cache_write_enable` must be set. The flash controller sequences each multi-page write pipeline command as a cache write sequence.

For a device that has multi-planes and supports multi-plane program commands, the NAND flash controller register `multiplane_operation`, in the `config` group, must be set. On receiving the multi-page pipeline write command, the flash controller sequences the device with multi-plane program commands

and expects that the host transfers data to the flash controller in an even-odd block increment addressing mode.

Set Up a Single Area for Pipeline Read-Ahead

To set up an area for pipeline read-ahead, perform the following steps:

1. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the starting address of the block to pre-read.
2. Write 0x20<*PP*> to the `Data` register, where the 0 sets this command as a read-ahead and <*PP*> is the number of pages to pre-read. The pages must not cross a block boundary. If a block boundary is crossed, the NAND flash controller generates an unsupported command (`unsup_cmd`) interrupt and drops the command.

The read-ahead command is a hint to the flash device to start loading the next page in the page buffer as soon as the previous page buffer operation has completed. After you set up the read-ahead, use a MAP01 command to actually read the data. In the MAP01 command, specify the same starting address as in the read-ahead.

If the read command received following a pipeline read-ahead request is not to a pre-read page, then an interrupt bit is set to 1 and the pipeline read-ahead or write-ahead registers are cleared. You must issue a new pipeline read-ahead request to re-load the same data. You must use MAP01 commands to read all of the data that is pre-read before the NAND flash controller returns to the idle state.

Set Up a Single Area for Pipeline Write-Ahead

To set up an area for pipeline write-ahead:

1. Write to the command register, setting the `CMD_MAP` field to 2 and the `BLK_ADDR` field to the starting address of the block to pre-write.
2. Write 0x21<PP> to the `Data` register, where the value 1 sets this command as a write-ahead and <PP> is the number of pages to pre-write. The pages must not cross a block boundary. If a block boundary is crossed, the NAND flash controller generates an unsupported command (`unsup_cmd`) interrupt and drops the command.

After you set up the write-ahead, use a MAP01 command to actually write the data. In the MAP01 command, specify the same starting address as in the write-ahead.

If the write command received following a pipeline write-ahead request is not to a pre-written page, then an interrupt bit is set to 1 and the pipeline read-ahead or write-ahead registers are cleared. You must issue a new pipeline write-ahead request to configure the write logic.

You must use MAP01 commands to write all of the data that is pre-written before the NAND flash controller returns to the idle state.

NAND Flash Controller Address Map and Register Definitions

The address map and register definitions for the NAND Flash Controller consist of the following regions:

NAND Controller Module Data (AXI Slave) Address Map on page 13-32
This address space is allocated for indexed addressing by the NAND flash controller.

NAND Flash Controller Module Registers (AXI Slave) Address Map on page 13-32
Registers in the NAND Flash Controller module accessible via its register AXI slave

device_spare_area_size Fields

Bit	Name	Description	Access	Reset
15:0	value	Controller will read Electronic Signature of devices and populate this field. The PAGE512 field of the System Manager NANDGRP_BOOTSTRAP register will determine the value of this field to be 16. Software could also choose to override the populated value.	RW	0x0

two_row_addr_cycles

Attached device has only 2 ROW address cycles

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80190

Offset: 0x190

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															flag RW 0x0

two_row_addr_cycles Fields

Bit	Name	Description	Access	Reset
0	flag	This flag must be set for devices which allow for 2 ROW address cycles instead of the usual 3. Alternatively, the TWOROWADDR field of the System Manager NANDGRP_BOOTSTRAP register when asserted will set this flag.	RW	0x0

multiplane_addr_restrict

Address restriction for multiplane commands

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB801A0

Offset: 0x1A0

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															flag RW 0x0

multiplane_addr_restrict Fields

Bit	Name	Description	Access	Reset
0	flag	This flag must be set for devices which require that during multiplane operations all but the address for the last plane should have their address cycles tied low. The last plane address cycles has proper values. This ensures multiplane address restrictions in the device.	RW	0x0

ecc_correction

Correction capability required

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB801B0

Offset: 0x1B0

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								value RW 0x8							

ecc_correction Fields

Bit	Name	Description	Access	Reset
7:0	value	The required correction capability can be a number less than the configured error correction capability. A smaller correction capability will lead to lesser number of ECC check-bits being written per ECC sector.	RW	0x8

read_mode

The type of read sequence that the controller will follow for pipe read commands.

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB801C0

Offset: 0x1C0

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

rdwr_en_lo_cnt

Read/Write Enable low pulse width

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB801F0

Offset: 0x1F0

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved											value RW 0x12				

rdwr_en_lo_cnt Fields

Bit	Name	Description	Access	Reset
4:0	value	Number of nand_mp_clk cycles that read or write enable will kept low to meet the min Trp/Twp parameter of the device. The value in this register plus rdwr_en_hi_cnt register value should meet the min cycle time of the device connected. The default value is calculated assuming the max nand_mp_clk time period of 4ns to work with ONFI Mode 0 mode of 100ns device cycle time. This assumes a 1x/4x clocking scheme.	RW	0x12

rdwr_en_hi_cnt

Read/Write Enable high pulse width

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80200

Offset: 0x200

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved											value RW 0xC				

rdwr_en_hi_cnt Fields

Bit	Name	Description	Access	Reset
4:0	value	Number of nand_mp_clk cycles that read or write enable will kept high to meet the min Treh/Tweh parameter of the device. The value in this register plus rdwr_en_lo_cnt register value should meet the min cycle time of the device connected. The default value is calculated assuming the max nand_mp_clk time period of 4ns to work with ONFI Mode 0 mode of 100ns device cycle time. This assumes a 1x/4x clocking scheme.	RW	0xC

max_rd_delay

Max round trip read data delay for data capture

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80210

Offset: 0x210

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved												value RW 0x0			

max_rd_delay Fields

Bit	Name	Description	Access	Reset
3:0	value	Number of nand_mp_clk cycles after generation of feedback nand_mp_clk pulse when it is safe to synchronize received data to nand_mp_clk domain. Data should have been registered with nand_mp_clk and stable by the time max_rd_delay cycles has elapsed. A default value of zero will mean a value of nand_mp_clk multiple minus one.	RW	0x0

cs_setup_cnt

Chip select setup time

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80220

Offset: 0x220

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved											value RW 0x3				

cs_setup_cnt Fields

Bit	Name	Description	Access	Reset
4:0	value	Number of nand_mp_clk cycles required for meeting chip select setup time. This register refers to device timing parameter Tcs. The value in this registers reflects the extra setup cycles for chip select before read/write enable signal is set low. The default value is calculated for ONFI Timing mode 0 Tcs = 70ns and maximum nand_mp_clk period of 4ns for 1x/4x clock multiple for 16ns cycle time device.	RW	0x3

spare_area_skip_bytes

Spare area skip bytes

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80230

Offset: 0x230

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved										value RW 0x0					

spare_area_skip_bytes Fields

Bit	Name	Description	Access	Reset
5:0	value	Number of bytes to skip from start of spare area before last ECC sector data starts. The bytes will be written with the value programmed in the spare_area_marker register. This register could be potentially used to preserve the bad block marker in the spare area by marking it good. The default value is zero which means no bytes will be skipped and last ECC sector will start from the beginning of spare area.	RW	0x0

spare_area_marker

Spare area marker value

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80240

Offset: 0x240

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
value RW 0xFFFF															

spare_area_marker Fields

Bit	Name	Description	Access	Reset
15:0	value	The value that will be written in the spare area skip bytes. This value will be used by controller while in the MAIN mode of data transfer. Only the least-significant 8 bits of the field value are used.	RW	0xFFFF

devices_connected

Number of Devices connected on one bank

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80250

Offset: 0x250

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved													value RW 0x0		

devices_connected Fields

Bit	Name	Description	Access	Reset
2:0	value	Indicates the number of devices connected to a bank. At reset, the value loaded is the maximum possible devices that could be connected in this configuration.	RW	0x0

die_mask

Indicates the die differentiator in case of NAND devices with stacked dies.

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80260

Offset: 0x260

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								value RW 0x0							

die_mask Fields

Bit	Name	Description	Access	Reset
7:0	value	The die_mask register information will be used for devices having address restrictions. For example, in certain Samsung devices, when the first address in a two-plane command is being sent, it is expected that the address is all zeros. But if the NAND device internally has multiple dies stacked, the die information (MSB of final row address) has to be sent. The value programmed in this register will be used to mask the address while sending out the last row address.	RW	0x0

first_block_of_next_plane

The starting block address of the next plane in a multi plane device.

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80270

Offset: 0x270

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
value RW 0x1															

first_block_of_next_plane Fields

Bit	Name	Description	Access	Reset
15:0	value	This values informs the controller of the plane structure of the device. In case the device is a multi plane device and the value here is 1, the controller understands that the next plane starts from Block number 1 and in conjunction with the number of planes parameter can decide upon the distribution of blocks in a plane in the device.	RW	0x1

write_protect

This register is used to control the assertion/de-assertion of the WP# pin to the device.

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80280

Offset: 0x280

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved															flag RW 0x1

write_protect Fields

Bit	Name	Description	Access	Reset
0	flag	When the controller is in reset, the WP# pin is always asserted to the device. Once the reset is removed, the WP# is de-asserted. The software will then have to come and program this bit to assert/de-assert the same. [list][*]1 - Write protect de-assert [*]0 - Write protect assert[/list]	RW	0x1

re_2_re

Timing parameter between re high to re low (Trhz) for the next bank

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB80290

Offset: 0x290

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved										value RW 0x32					

re_2_re Fields

Bit	Name	Description	Access	Reset
5:0	value	Signifies the number of bus interface nand_mp_clk clocks that should be introduced between read enable going high to a bank to the read enable going low to the next bank. The number of clocks is the function of device parameter Trhz and controller clock frequency.	RW	0x32

por_reset_count

The number of cycles the controller waits after reset to issue the first RESET command to the device.

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB802A0

Offset: 0x2A0

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
value RW 0x13B															

por_reset_count Fields

Bit	Name	Description	Access	Reset
15:0	value	The controller waits for this number of cycles before issuing the first RESET command to the device. The number in this register is multiplied internally by 16 in the controller to form the final reset wait count.	RW	0x13B

watchdog_reset_count

The number of cycles the controller waits before flagging a watchdog timeout interrupt.

Module Instance	Base Address	Register Address
nandregs	0xFFB80000	0xFFB802B0

Offset: 0x2B0

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved

8	partition	if set, Partition logic is present in hardware.	RO	0x0
7	cmd_dma	Not implemented.	RO	0x0
6	dma	if set, DATA-DMA is present in hardware.	RO	0x1
1:0	n_banks	Maximum number of banks supported by hardware. This is an encoded value. [list][*]0 - Two banks [*]1 - Four banks [*]2 - Eight banks [*]3 - Sixteen banks[/list]	RO	0x1

Interrupt and Status Registers Register Descriptions

Contains interrupt and status registers of controller accessible by software.

Offset: `0x400`

transfer_mode on page 13-80
Current data transfer mode is Main only, Spare only or Main+Spare. This information is per bank.

intr_status0 on page 13-80
Interrupt status register for bank 0

intr_en0 on page 13-82
Enables corresponding interrupt bit in interrupt register for bank 0

page_cnt0 on page 13-83
Decrementing page count bank 0

err_page_addr0 on page 13-84
Erred page address bank 0

err_block_addr0 on page 13-84
Erred block address bank 0

intr_status1 on page 13-85
Interrupt status register for bank 1

intr_en1 on page 13-86
Enables corresponding interrupt bit in interrupt register for bank 1

page_cnt1 on page 13-88
Decrementing page count bank 1

err_page_addr1 on page 13-89
Erred page address bank 1

err_block_addr1 on page 13-89
Erred block address bank 1

intr_status2 on page 13-90
Interrupt status register for bank 2

intr_en2 on page 13-91
Enables corresponding interrupt bit in interrupt register for bank 2

page_cnt2 on page 13-93
Decrementing page count bank 2

err_page_addr2 on page 13-93
Erred page address bank 2

err_block_addr2 on page 13-94
Erred block address bank 2

intr_status3 on page 13-94
Interrupt status register for bank 3

intr_en3 on page 13-96
Enables corresponding interrupt bit in interrupt register for bank 3

page_cnt3 on page 13-97
Decrementing page count bank 3

err_page_addr3 on page 13-98
Erred page address bank 3

err_block_addr3 on page 13-98
Erred block address bank 3

transfer_mode

Current data transfer mode is Main only, Spare only or Main+Spare. This information is per bank.

intr_status0 Fields

Bit	Name	Description	Access	Reset
15	page_xfer_inc	For every page of data transfer to or from the device, this bit will be set.	RW	0x0
14	pipe_cmd_err	A pipeline command sequence has been violated. This occurs when Map 01 page read/write address does not match the corresponding expected address from the pipeline commands issued earlier.	RW	0x0
13	rst_comp	Controller has finished reset and initialization process	RW	0x0
12	INT_act	R/B pin of device transitioned from low to high	RW	0x0
11	unsup_cmd	An unsupported command was received. This interrupt is set when an invalid command is received, or when a command sequence is broken.	RW	0x0
10	locked_blk	The address to program or erase operation is to a locked block and the operation failed due to this reason	RW	0x0
9	pipe_cpybck_cmd_comp	A pipeline command or a copyback bank command has completed on this particular bank	RW	0x0
8	erase_comp	Device erase operation complete	RW	0x0
7	program_comp	Device finished the last issued program command.	RW	0x0
6	load_comp	Device finished the last issued load command.	RW	0x0

Bit	Name	Description	Access	Reset
5	erase_fail	Erase failure occurred in the device on issuance of a erase command. err_block_addr and err_page_addr contain the block address and page address that failed erase operation.	RW	0x0
4	program_fail	Program failure occurred in the device on issuance of a program command. err_block_addr and err_page_addr contain the block address and page address that failed program operation.	RW	0x0
3	time_out	Watchdog timer has triggered in the controller due to one of the reasons like device not responding or controller state machine did not get back to idle	RW	0x0
2	dma_cmd_comp	Not implemented.	RW	0x0
0	ecc_uncor_err	Ecc logic detected uncorrectable error while reading data from flash device.	RW	0x0

intr_en0

flash_burst_length Fields

Bit	Name	Description	Access	Reset
31:8	reserved	Reserved	RW	0x0
4	continous_burst	When this bit is set, the Data DMA will burst the entire page from/to the flash device. Please make sure that the host system can provide/sink data at a fast pace to avoid unnecessary pausing of data on the device interface.	RW	0x0

Bit	Name	Description	Access	Reset
1:0	value	Sets the burst used by data dma for transferring data to/from flash device. This burst length is different and is larger than the burst length on the host bus so that larger amount of data can be transferred to/from device, descreasing controller data transfer overhead in the process. 00 - 64 bytes, 01 - 128 bytes, 10 - 256 bytes, 11 - 512 bytes. The host burst size multiplied by the number of outstanding requests on the host side should be greater than equal to this value. If not, the device side burst length will be equal to host side burst length.	RW	0x1

Date	Version	Changes
December 2014	2014.12.15	Maintenance release
July 2014	2014.07.31	Updated address map and register definitions.
June 2014	2014.06.30	• Added address map and register definitions. • Removed Command DMA section.
February 2014	2014.02.28	Maintenance release
December 2013	2013.12.30	Maintenance release
November 2012	1.2	• Supports one 8-bit device • Show additional supported block sizes • Bad block marker handling
May 2012	1.1	Added programming model section.
January 2012	1.0	Initial release.

SD/MMC Controller 14

2014.12.15

av_5v4

The hard processor system (HPS) provides a Secure Digital/Multimedia Card (SD/MMC) controller for interfacing to external SD and MMC flash cards, secure digital I/O (SDIO) devices, and Consumer Electronics Advanced Transport Architecture (CE-ATA) hard drives. The SD/MMC controller enables you to store boot images and boot the processor system from the removable flash card. You can also use the flash card to expand the on-board storage capacity for larger applications or user data. Other applications include interfacing to embedded SD (eSD) and embedded MMC (eMMC) nonremovable flash devices.

The SD/MMC controller is based on the Synopsys DesignWare Mobile Storage Host (SD/MMC controller) controller.

This document refers to SD/SDIO commands, which are documented in detail in the *Physical Layer Simplified Specification, Version 3.01* and the *SDIO Simplified Specification Version 2.00* described on the SD Association website.

Related Information

- **www.sdcard.org**
  To learn more about how SD technology works, visit the SD Association website.
- **Introduction to the Arria V Hard Processor System** on page 1-1
  The base addresses of all modules are also listed in the Introduction to the Hard Processor System chapter.

Features of the SD/MMC Controller

The HPS SD/MMC controller offers the following features:

- Supports HPS boot from mobile storage
- Supports the following standards or card types:
  - SD, including eSD—version 3.0
  - SDIO, including embedded SDIO (eSDIO)—version 3.0

    Note: The previous items do not support SDR50, SDR104, and DDR50 modes.
  - CE-ATA—version 1.1
- Supports various types of multimedia cards, MMC version 4.41
  - MMC: 1-bit data bus
  - Reduced-size MMC (RSMMC): 1-bit and 4-bit data bus
  - MMCMobile: 1-bit data bus

  Note: Does not support DDR mode.
- Supports embedded MMC (eMMC) version 4.41
  - 1-bit and 4-bit data bus

  Note: Does not support DDR mode.
- Integrated descriptor-based direct memory access (DMA)
- Internal 4 KB receive and transmit FIFO buffer

The SD/MMC controller does not directly support voltage switching, card interrupts, or back-end power control of eSDIO card devices. However, you can connect these signals to general-purpose I/Os (GPIOs).

The SD/MMC controller does not contain a reset output as part of the external card interface. To reset the flash card device, consider using a general purpose output pin.

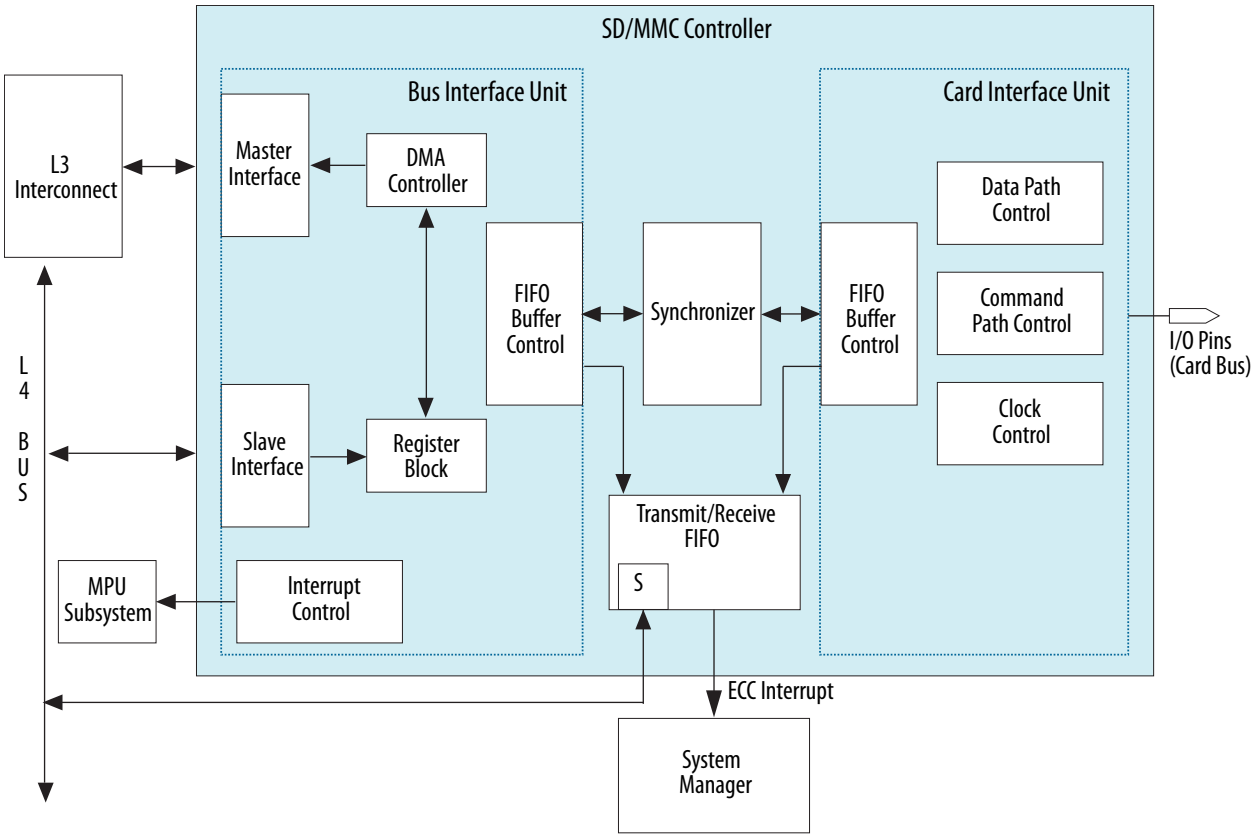
SD/MMC Controller Block Diagram and System Integration

The SD/MMC controller includes a bus interface unit (BIU) and a card interface unit (CIU). The BIU provides a slave interface for a host to access the control and status registers (CSRs). Additionally, this unit also provides independent FIFO buffer access through a DMA interface. The DMA controller is responsible for exchanging data between the system memory and FIFO buffer. The DMA registers are accessible by the host to control the DMA operation. The CIU supports the SD, MMC, and CE-ATA protocols on the controller, and provides clock management through the clock control block. The

(36) Because SD cards initially operate at 3.0 V and can switch to 1.8V after power-up and the BSEL values are constant during the boot process, transceivers are required to support level-shifting and isolation.
(37) SDR25 speed mode requires 1.8-V signaling. Note that even if a card supports UHS-I modes (for example SDR50, SDR104, DDR50) it can still communicate at the lower speeds (for example SDR12, SDR25).
(38) Where supported, external transceivers are needed to switch the voltage.
(39) SPI mode is obsolete in the MMC 4.41 specification.
(40) Supports a maximum clock rate of 50 MHz instead of 52 MHz (specified in MMC specification).

interrupt control block for generating an interrupt connects to the generic interrupt controller in the ARM Cortex-A9 microprocessor unit (MPU) subsystem.

Figure 14-1: SD/MMC Controller Connectivity



Functional Description of the SD/MMC Controller

This section describes the SD/MMC controller components and how the controller operates.

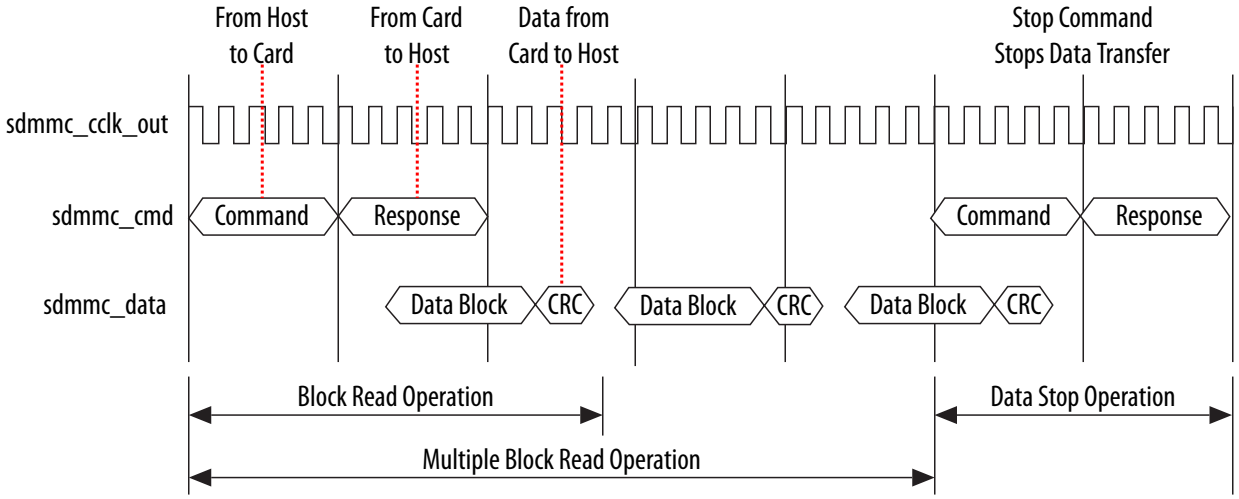
SD/MMC/CE-ATA Protocol

The SD/MMC/CE-ATA protocol is based on command and data bit streams that are initiated by a start bit and terminated by a stop bit. Additionally, the SD/MMC controller provides a reference clock and is the only master interface that can initiate a transaction. †

- Command—a token transmitted serially on the CMD pin that starts an operation.†
- Response—a token from the card transmitted serially on the CMD pin in response to certain commands.†
- Data—transferred serially using the data pins for data movement commands.†

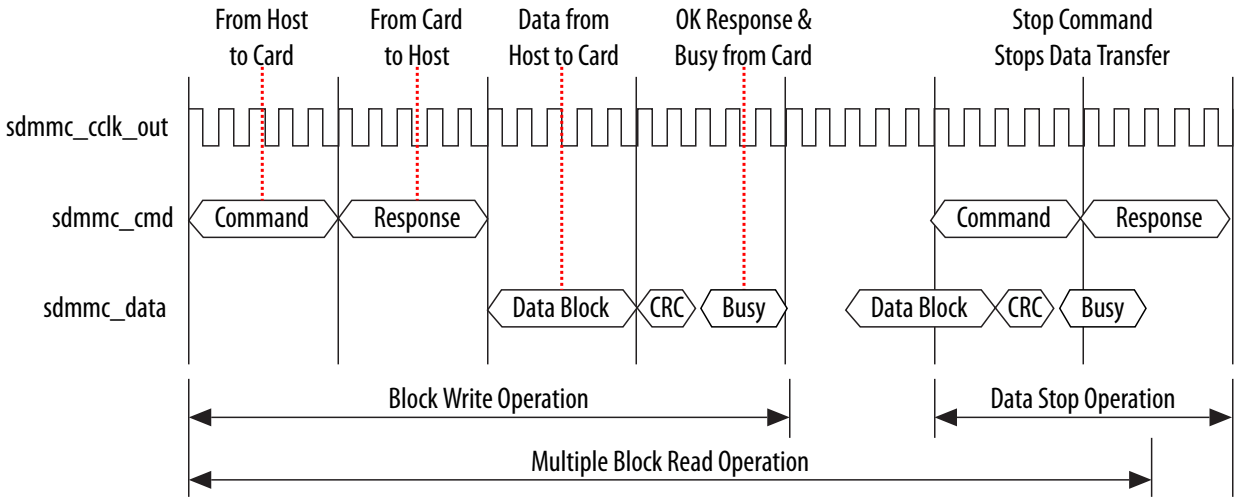
In the following figure, the clock is a representative only and does not show the exact number of clock cycles.†

Figure 14-2: Multiple-Block Read Operation†



The following figure illustrates an example of a command token sent by the host in a multiple-block write operation.

Figure 14-3: Multiple-Block Write Operation†



BIU

The Bus Interface Unit (BIU) interfaces with the Card Interface Unit (CIU), and is connected to the level 3 (L3) interconnect and level 4 (L4) peripheral buses. The BIU consists of the following primary functional blocks, which are defined in the following sections:

- Slave interface
- Register block
- FIFO buffer
- Interrupt control
- Internal DMA controller

Slave Interface

The host processor accesses the SD/MMC controller registers and data FIFO buffers through the slave interface.

Register Block

The register block is part of the BIU and provides read and write access to the CSRs.†

All registers reside in the BIU clock domain, `l4_mp_clk`. When a command is sent to a card by setting the start command bit (`start_cmd`) of the command register (`cmd`) to 1, all relevant registers needed for the CIU operation are copied to the CIU block. During this time, software must not write to the registers that are transferred from the BIU to the CIU. The software must wait for the hardware to reset the `start_cmd` bit to 0 before writing to these registers again. The register unit has a hardware locking feature to prevent illegal writes to registers.†

Registers Locked Out Pending Command Acceptance

After a command start is issued by setting the `start_cmd` bit of the `cmd` register, the following registers cannot be rewritten until the command is accepted by the CIU:†

- Command (`cmd`)†
- Command argument (`cmdarg`)†
- Byte count (`bytcnt`)†
- Block size (`blksiz`)†
- Clock divider (`clkdiv`)†
- Clock enable (`clkena`)†
- Clock source (`clksrc`)†
- Timeout (`tmout`)†
- Card type (`ctype`)†

The hardware resets the `start_cmd` bit after the CIU accepts the command. If a host write to any of these registers is attempted during this locked time, the write is ignored and the hardware lock write error bit (`hle`) is set to 1 in the raw interrupt status register (`rintsts`). Additionally, if the interrupt is enabled and not masked for a hardware lock error, an interrupt is sent to the host.†

After a command is accepted, you can send another command to the CIU—which has a one-deep command queue—under the following conditions:†

- If the previous command is not a data transfer command, the new command is sent to the SD/MMC/CE-ATA card once the previous command completes.†
- If the previous command is a data transfer command and if the wait previous data complete bit (`wait_prvdata_complete`) of the `cmd` register is set to 1 for the new command, the new command is sent to the SD/MMC/CE-ATA card only when the data transfer completes.†
- If the `wait_prvdata_complete` bit is 0, the new command is sent to the SD/MMC/CE-ATA card as soon as the previous command is sent. Typically, use this feature to stop or abort a previous data transfer or query the card status in the middle of a data transfer.†

Interrupt Controller Unit

The interrupt controller unit generates an interrupt that depends on the `rintsts` register, the interrupt mask register (`intmask`), and the interrupt enable bit (`int_enable`) of the control register (`ctrl`). Once an interrupt condition is detected, the controller sets the corresponding interrupt bit in the `rintsts` register. The bit in the `rintsts` register remains set until the software clears the bit by writing a 1 to the interrupt bit; writing a 0 leaves the bit untouched.

The interrupt controller unit generates active high, level sensitive interrupts that are asserted only when at least one bit in the `rintsts` register is set to 1, the corresponding `intmask` register bit is 1, and the `int_enable` bit of the `ctrl` register is 1.

The `int_enable` bit of the `ctrl` register is cleared during a power-on reset, and the `intmask` register bits are set to 0x0000000, which masks all the interrupts.

Table 14-3: Interrupt Status Register Bits†

Bits	Interrupt	Description
16	SDIO Interrupts†	Interrupts from SDIO cards.†
15	End Bit Error (read)/Write no CRC (EBE)†	Error in end-bit during read operation, or no data CRC received during write operation.† **Note:** For MMC CMD19, there may be no CRC status returned by the card. Hence, EBE is set for CMD19. The application should not treat this as an error. †
14	Auto Command Done (ACD)†	Stop/abort commands automatically sent by card unit and not initiated by host; similar to Command Done (CD) interrupt. † **Recommendation:** Software typically need not enable this for non CE-ATA accesses; Data Transfer Over (DTO) interrupt that comes after this interrupt determines whether data transfer has correctly competed. For CE-ATA accesses, if the software sets `send_auto_stop_ccsd` bit in the control register, then software should enable this bit.†
13	Start Bit Error (SBE)†	Error in data start bit when data is read from a card. In 4-bit mode, if all data bits do not have start bit, then this error is set. †
12	Hardware Locked write Error (HLE)†	During hardware-lock period, write attempted to one of locked registers. †

Bits	Interrupt	Description
11	FIFO Underrun/Overrun Error (FRUN)†	Host tried to push data when FIFO was full, or host tried to read data when FIFO was empty. Typically this should not happen, except due to error in software. † Card unit never pushes data into FIFO when FIFO is full, and pop data when FIFO is empty. † If IDMAC (Internal Direct Memory Access Controller) is enabled, FIFO underrun/overrun can occur due to a programming error on MSIZE and watermark values in FIFOTH register; for more information, refer to *Internal Direct Memory Access Controller (IDMAC)* section in the "Synopsys DesignWare Cores Mobile Storage Host Databook".†
10	Data Starvation by Host Timeout (HTO)†	To avoid data loss, card clock out (`cclk_out`) is stopped if FIFO is empty when writing to card, or FIFO is full when reading from card. Whenever card clock is stopped to avoid data loss, data-starvation timeout counter is started with data-timeout value. This interrupt is set if host does not fill data into FIFO during write to card, or does not read from FIFO during read from card before timeout period. † Even after timeout, card clock stays in stopped state, with CIU state machines waiting. It is responsibility of host to push or pop data into FIFO upon interrupt, which automatically restarts `cclk_out` and card state machines. † Even if host wants to send stop/abort command, it still must ensure to push or pop FIFO so that clock starts in order for stop/abort command to send on cmd signal along with data that is sent or received on data line. †
9	Data Read Timeout (DRTO)/Boot Data Start (BDS)†	• In Normal functioning mode: Data read timeout (DRTO) Data timeout occurred. Data Transfer Over (DTO) also set if data timeout occurs. † • In Boot Mode: Boot Data Start (BDS) When set, indicates that SD/MMC controller has started to receive boot data from the card. A write to this register with a value of 1 clears this interrupt.†

Bits	Interrupt	Description
8	Response Timeout (RTO)/ Boot Ack Received (BAR)†	• In Normal functioning mode: Response timeout (RTO) Response timeout occurred. Command Done (CD) also set if response timeout occurs. If command involves data transfer and when response times out, no data transfer is attempted by SD/MMC controller.† • In Boot Mode: Boot Ack Received (BAR) When expect_boot_ack is set, on reception of a boot acknowledge pattern—0-1-0—this interrupt is asserted. A write to this register with a value of 1 clears this interrupt.†
7	Data CRC Error (DCRC)†	Received Data CRC does not match with locally-generated CRC in CIU; expected when a negative CRC is received. †
6	Response CRC Error (RCRC)†	Response CRC does not match with locally-generated CRC in CIU.†
5	Receive FIFO Data Request (RXDR)†	Interrupt set during read operation from card when FIFO level is greater than Receive-Threshold level.† **Recommendation:** In DMA modes, this interrupt should not be enabled.† ISR, in non-DMA mode: `pop RX_WMark + 1 data from FIFO` †

4	Transmit FIFO Data Request (TXDR)†	Interrupt set during write operation to card when FIFO level reaches less than or equal to Transmit-Threshold level.†
		Recommendation: In DMA modes, this interrupt should not be enabled.†
		ISR in non-DMA mode: †
		`if (pending_bytes > \†`
		`(FIFO_DEPTH - TX_WMark))†`
		`push (FIFO_DEPTH - \†`
		`TX_WMark) data into FIFO†`
		`else†`
		`push pending_bytes data \†`
		`into FIFO†`

Bits	Interrupt	Description
3	Data Transfer (DTO)†	Data transfer completed, even if there is Start Bit Error or CRC error. This bit is also set when "read data-timeout" occurs or CCS is sampled from CE-ATA device.† **Recommendation:** In non-DMA mode, when data is read from card, on seeing interrupt, host should read any pending data from FIFO. In DMA mode, DMA controllers guarantee FIFO is flushed before interrupt.† **Note:** DTO bit is set at the end of the last data block, even if the device asserts MMC busy after the last data block.†
2	Command Done (CD)†	Command sent to card and received response from card, even if Response Error or CRC error occurs. Also set when response timeout occurs or CCSD sent to CE-ATA device.†
1	Response Error (RE)†	Error in received response set if one of following occurs:† • Transmission bit != 0† • Command index mismatch† • End-bit != 1†
0	Card-Detect (CDT)†	When one or more cards inserted or removed, this interrupt occurs. Software should read card-detect register (CDETECT, 0x50) to determine current card status.† **Recommendation:** After power-on and before enabling interrupts, software should read card detect register and store it in memory. When interrupt occurs, it should read card detect register and compare it with value stored in memory to determine which card(s) were removed/inserted. Before exiting ISR, software should update memory with new card-detect value.†

Interrupt Setting and Clearing

The SDIO Interrupts, Receive FIFO Data Request, and Transmit FIFO Data Request interrupts are set by level-sensitive interrupt sources. Therefore, the interrupt source must be first cleared before you can reset the interrupt's corresponding bit in the `rintsts` register to 0.†

For example, on receiving the Receive FIFO Data Request interrupt, the FIFO buffer must be emptied so that the FIFO buffer count is not greater than the RX watermark, which causes the interrupt to be triggered.†

The rest of the interrupts are triggered by single clock-pulse-width sources.†

FIFO Buffer

The SD/MMC controller has a 4 KB data FIFO buffer for storing transmit and receive data. The FIFO buffer memory supports error correction codes (ECCs). Both interfaces to the FIFO buffer support single and double bit error injection. The enable and error injection pins are inputs driven by the system manager and the status pins are outputs driven to the MPU subsystem.

The SD/MMC controller provides outputs to notify the system manager when single-bit correctable errors are detected (and corrected), and when double-bit (uncorrectable) errors are detected. The system manager generates an interrupt to the GIC when an ECC error is detected.

Related Information

System Manager on page 5-1

Internal DMA Controller

The internal DMA controller has a CSR and a single transmit or receive engine, which transfers data from system memory to the card and vice versa. The controller uses a descriptor mechanism to efficiently move data from source to destination with minimal host processor intervention. You can set up the controller to interrupt the host processor in situations such as transmit and receive data transfer completion from the card, as well as other normal or error conditions. The DMA controller and the host driver communicate through a single data structure.†

The internal DMA controller transfers the data received from the card to the data buffer in the system memory, and transfers transmit data from the data buffer in the memory to the controller's FIFO buffer. Descriptors that reside in the system memory act as pointers to these buffers.†

A data buffer resides in the physical memory space of the system memory and consists of complete or partial data. The buffer status is maintained in the descriptor. Data chaining refers to data that spans multiple data buffers. However, a single descriptor cannot span multiple data buffers.†

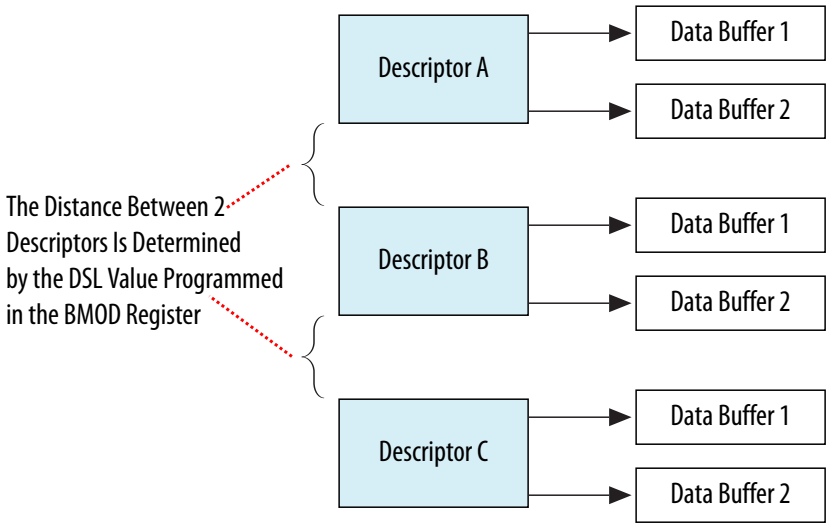
A single descriptor is used for both reception and transmission. The base address of the list is written into the descriptor list base address register (`dbaddr`). A descriptor list is forward linked. The last descriptor can point back to the first entry to create a ring structure. The descriptor list resides in the physical memory address space of the host. Each descriptor can point to a maximum of two data buffers.†

Internal DMA Controller Descriptors

The internal DMA controller uses these types of descriptor structures:†

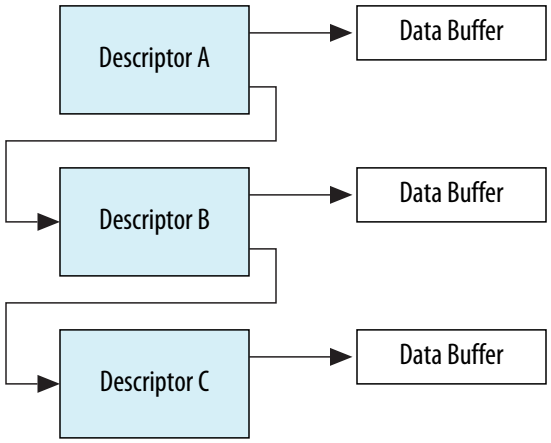
- Dual-buffer structure—The distance between two descriptors is determined by the skip length value written to the descriptor skip length field (`dsl`) of the bus mode register (`bmod`).†

Figure 14-4: Dual-Buffer Descriptor Structure†



- Chain structure—Each descriptor points to a unique buffer, and to the next descriptor in a linked list.†

Figure 14-5: Chain Descriptor Structure†



Internal DMA Controller Descriptor Address

The descriptor address must be aligned to the 32-bit bus. Each descriptor contains 16 bytes of control and status information.†

Table 14-4: Descriptor Format

Name	Off-set	31	30	29:27	26	25:14	13	12:7	6	5	4	3	2	1	0

DES1	4	—				BS2		BS1							

Name	Off-set	31	30	29:27	26	25:14	13	12:7	6	5	4	3	2	1	0
DES2	8	BAP1													
DES3	12	BAP2 or Next Descriptor Address													

Related Information

Internal DMA Controller Descriptor Fields on page 14-13
Refer to this table for information about each of the bits of the descriptor.

Internal DMA Controller Descriptor Fields

The DES0 field in the internal DMA controller descriptor contains control and status information.

Table 14-5: Internal DMA Controller DES0 Descriptor Field†

Bits	Name	Description
31	OWN	When set to 1, this bit indicates that the descriptor is owned by the internal DMA controller. When this bit is set to 0, it indicates that the descriptor is owned by the host. The internal DMA controller resets this bit to 0 when it completes the data transfer.
30	Card Error Summary (CES)	The CES bit indicates whether a transaction error occurred. The CES bit is the logical OR of the following error bits in the `rintsts` register. • End-bit error (`ebe`) • Response timeout (`rto`) • Response CRC (`rcrc`) • Start-bit error (`sbe`) • Data read timeout (`drto`) • Data CRC for receive (`dcrc`) • Response error (`re`)
29:6	Reserved	—
5	End of Ring (ER)	When set to 1, this bit indicates that the descriptor list reached its final descriptor. The internal DMA controller returns to the base address of the list, creating a descriptor ring. ER is meaningful for only a dual-buffer descriptor structure.
4	Second Address Chained (CH)	When set to 1, this bit indicates that the second address in the descriptor is the next descriptor address rather than the second buffer address. When this bit is set to 1, BS2 (DES1[25:13]) must be all zeros.

Bits	Name	Description
3	First Descriptor (FS)	When set to 1, this bit indicates that this descriptor contains the first buffer of the data. If the size of the first buffer is 0, next descriptor contains the beginning of the data.
2	Last Descriptor (LD)	When set to 1, this bit indicates that the buffers pointed to by this descriptor are the last buffers of the data.
1	Disable Interrupt on Completion (DIC)	When set to 1, this bit prevents the setting of the TI/RI bit of the internal DMA controller status register (`idsts`) for the data that ends in the buffer pointed to by this descriptor.
0	Reserved	—

The DES1 descriptor field contains the buffer size.

Table 14-6: Internal DMA Controller DES1 Descriptor Field†

Bits	Name	Description
31:26	Reserved	—
25:13	Buffer 2 Size (BS2)	This field indicates the second data buffer byte size. The buffer size must be a multiple of four. When the buffer size is not a multiple of four, the resulting behavior is undefined. This field is not valid if DES0[4] is set to 1.
12:0	Buffer 1 Size (BS1)	Indicates the data buffer byte size, which must be a multiple of four bytes. When the buffer size is not a multiple of four, the resulting behavior is undefined. If this field is 0, the DMA ignores the buffer and proceeds to the next descriptor for a chain structure, or to the next buffer for a dual-buffer structure. If there is only one descriptor and only one buffer to be programmed, you need to use only buffer 1 and not buffer 2.

The DES2 descriptor field contains the address pointer to the data buffer.

Table 14-7: Internal DMA Controller DES2 Descriptor Field†

Bits	Name	Description
31:0	Buffer Address Pointer 1 (BAP1)	These bits indicate the physical address of the first data buffer. The internal DMA controller ignores DES2 [1:0], because it only performs 32-bit aligned accesses.

The DES3 descriptor field contains the address pointer to the next descriptor if the present descriptor is not the last descriptor in a chained descriptor structure or the second buffer address for a dual-buffer structure.†

Table 14-8: Internal DMA Controller DES3 Descriptor Field†

Bits	Name	Description
31:0	Buffer Address Pointer 2 (BAP2) or Next Descriptor Address	These bits indicate the physical address of the second buffer when the dual-buffer structure is used. If the Second Address Chained (DES0[4]) bit is set to 1, this address contains the pointer to the physical memory where the next descriptor is present. If this is not the last descriptor, the next descriptor address pointer must be aligned to 32 bits. Bits 1 and 0 are ignored.

Host Bus Burst Access

The internal DMA controller attempts to issue fixed-length burst transfers on the master interface if configured using the fixed burst bit (`fb`) of the `bmod` register. The maximum burst length is indicated and limited by the programmable burst length (`pbl`) field of the `bmod` register. When descriptors are being fetched, the master interface always presents a burst size of four to the interconnect.†

The internal DMA controller initiates a data transfer only when sufficient space to accommodate the configured burst is available in the FIFO buffer or the number of bytes to the end of transfer is less than the configured burst-length. When the DMA master interface is configured for fixed-length bursts, it transfers data using the most efficient combination of INCR4/8/16 and SINGLE transactions. If the DMA master interface is not configured for fixed length bursts, it transfers data using INCR (undefined length) and SINGLE transactions.†

Host Data Buffer Alignment

The transmit and receive data buffers in system memory must be aligned to a 32-bit boundary.

Buffer Size Calculations

The driver knows the amount of data to transmit or receive. For transmitting to the card, the internal DMA controller transfers the exact number of bytes from the FIFO buffer, indicated by the buffer size field of the DES1 descriptor field.†

If a descriptor is not marked as last (with the LD bit of the DES0 field set to 0) then the corresponding buffer(s) of the descriptor are considered full, and the amount of valid data in a buffer is accurately indicated by its buffer size field. If a descriptor is marked as last, the buffer might or might not be full, as

indicated by the buffer size in the DES1 field. The driver is aware of the number of locations that are valid.† The driver is expected to ignore the remaining, invalid bytes.

Internal DMA Controller Interrupts

Interrupts can be generated as a result of various events. The `idsts` register contains all the bits that might cause an interrupt. The internal DMA controller interrupt enable register (`idinten`) contains an enable bit for each of the events that can cause an interrupt to occur.†

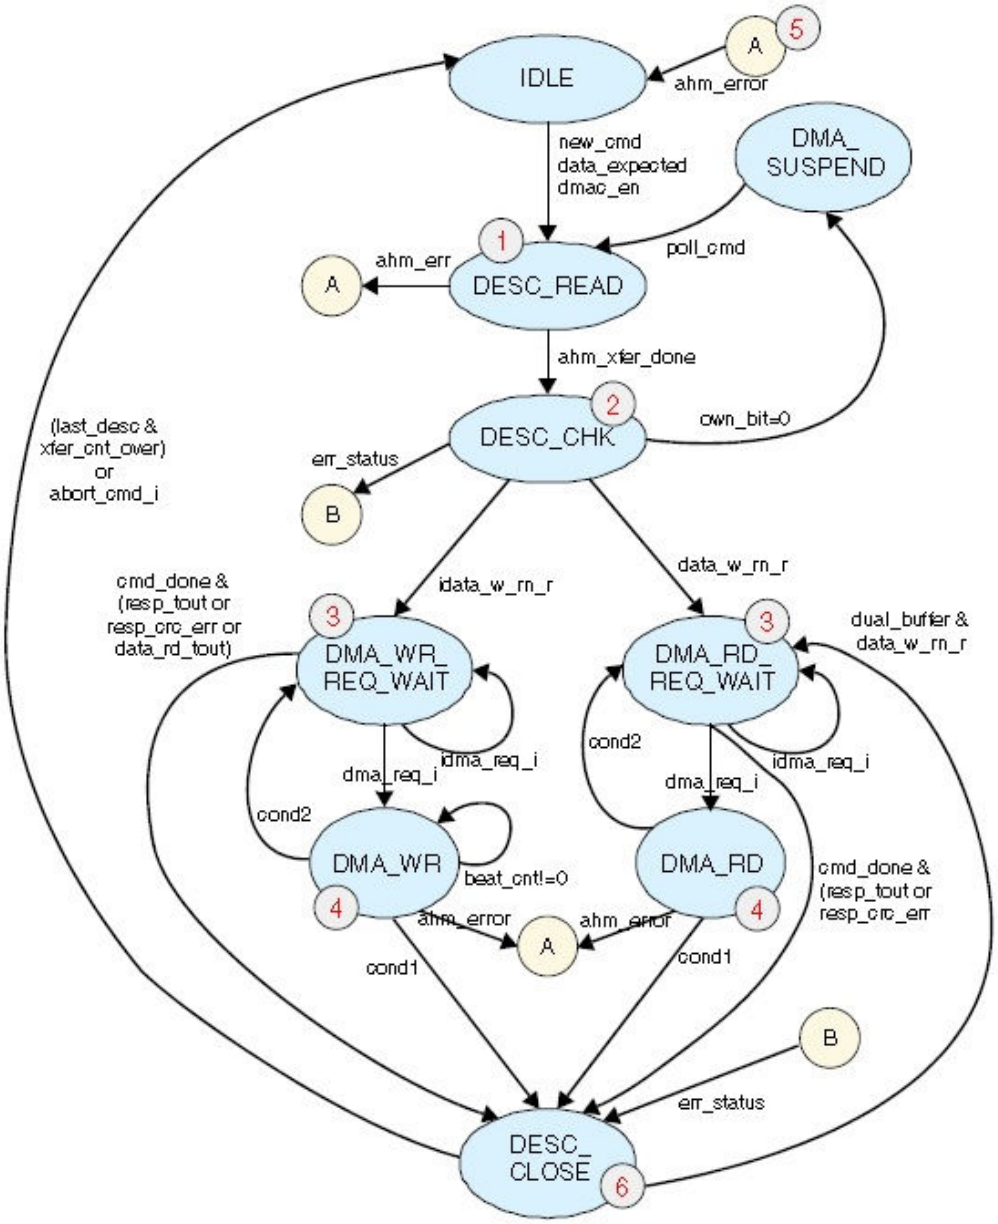
There are two summary interrupts—the normal interrupt summary bit (`nis`) and the abnormal interrupt summary bit (`ais`)—in the `idsts` register.† The `nis` bit results from a logical OR of the transmit interrupt (`ti`) and receive interrupt (`ri`) bits in the `idsts` register. The `ais` bit is a logical OR result of the fatal bus error interrupt (`fbe`), descriptor unavailable interrupt (`du`), and card error summary interrupt (`ces`) bits in the `idsts` register.

Interrupts are cleared by writing a 1 to the corresponding bit position.† If a 0 is written to an interrupt's bit position, the write is ignored, and does not clear the interrupt. When all the enabled interrupts within a group are cleared, the corresponding summary bit is set to 0. When both the summary bits are set to 0, the interrupt signal is de-asserted.†

Interrupts are not queued. If another interrupt event occurs before the driver has responded to the previous interrupt, no additional interrupts are generated. For example, the `ri` bit of the `idsts` register indicates that one or more data has been transferred to the host buffer.†

An interrupt is generated only once for simultaneous, multiple events. The driver must scan the `idsts` register for the interrupt cause.† The final interrupt signal from the controller is a logical OR of the interrupts from the BIU and internal DMA controller.

Internal DMA Controller Functional State Machine†



The following list explains each state of the functional state machine:†

1. The internal DMA controller performs four accesses to fetch a descriptor.†
2. The DMA controller stores the descriptor information internally. If it is the first descriptor, the controller issues a FIFO buffer reset and waits until the reset is complete.†
3. The internal DMA controller checks each bit of the descriptor for the correctness. If bit mismatches are found, the appropriate error bit is set to 1 and the descriptor is closed by setting the OWN bit in the DES0 field to 1.†

   The `rintsts` register indicates one of the following conditions:†

- Response timeout†
- Response CRC error†
- Data receive timeout†
- Response error†

4. The DMA waits for the RX watermark to be reached before writing data to system memory, or the TX watermark to be reached before reading data from system memory. The RX watermark represents the number of bytes to be locally stored in the FIFO buffer before the DMA writes to memory. The TX watermark represents the number of free bytes in the local FIFO buffer before the DMA reads data from memory.†
5. If the value of the programmable burst length (PBL) field is larger than the remaining amount of data in the buffer, single transfers are initiated. If dual buffers are being used, and the second buffer contains no data (buffer size = 0), the buffer is skipped and the descriptor is closed.†
6. The OWN bit in descriptor is set to 0 by the internal DMA controller after the data transfer for one descriptor is completed. If the transfer spans more than one descriptor, the DMA controller fetches the next descriptor. If the transfer ends with the current descriptor, the internal DMA controller goes to idle state after setting the `ri` bit or the `ti` bit of the `idsts` register. Depending on the descriptor structure (dual buffer or chained), the appropriate starting address of descriptor is loaded. If it is the second data buffer of dual buffer descriptor, the descriptor is not fetched again.†

Abort During Internal DMA Transfer

If the host issues an SD/SDIO STOP_TRANSMISSION command (CMD12) to the card while data transfer is in progress, the internal DMA controller closes the present descriptor after completing the data transfer until a Data Transfer Over (DTO) interrupt is asserted. Once a STOP_TRANSMISSION command is issued, the DMA controller performs single burst transfers.†

- For a card write operation, the internal DMA controller keeps writing data to the FIFO buffer after fetching it from the system memory until a DTO interrupt is asserted. This is done to keep the card clock running so that the STOP_TRANSMISSION command is reliably sent to the card.†
- For a card read operation, the internal DMA controller keeps reading data from the FIFO buffer and writes to the system memory until a DTO interrupt is generated. This is required because DTO interrupt is not generated until and unless all the FIFO buffer data is emptied.†

Note: For a card write abort, only the current descriptor during which a STOP_TRANSMISSION command is issued is closed by the internal DMA controller. The remaining unread descriptors are not closed by the internal DMA controller.†

Note: For a card read abort, the internal DMA controller reads the data out of the FIFO buffer and writes them to the corresponding descriptor data buffers. The remaining unread descriptors are not closed.†

Fatal Bus Error Scenarios

A fatal bus error occurs due to an error response through the master interface. This error is a system error, so the software driver must not perform any further setup on the controller. The only recovery mechanism from such scenarios is to perform one of the following tasks:†

- Issue a reset to the controller through the reset manager.†
- Issue a program controller reset by writing to the controller reset bit (`controller_reset`) of the `ctrl` register.†

FIFO Buffer Overflow and Underflow

During normal data transfer conditions, FIFO buffer overflow and underflow does not occur. However, if there is a programming error, a FIFO buffer overflow or underflow can result. For example, consider the following scenarios.†

For transmit:†

- PBL=4†
- TX watermark = 1†

For these programming values, if the FIFO buffer has only one location empty, the DMA attempts to read four words from memory even though there is only one word of storage available. This results in a FIFO Buffer Overflow interrupt.†

For receive:†

- PBL=4†
- RX watermark = 1†

For these programming values, if the FIFO buffer has only one location filled, the DMA attempts to write four words, even though only one word is available. This results in a FIFO Buffer Underflow interrupt.†

The driver must ensure that the number of bytes to be transferred, as indicated in the descriptor, is a multiple of four bytes. For example, if the `bytcnt` register = 13, the number of bytes indicated in the descriptor must be rounded up to 16 because the length field must always be a multiple of four bytes.†

PBL and Watermark Levels

This table shows legal PBL and FIFO buffer watermark values for internal DMA controller data transfer operations.†

Table 14-9: PBL and Watermark Levels†

PBL (Number of transfers)	TX/RX FIFO Buffer Watermark Value
1	greater than or equal to 1
4	greater than or equal to 4
8	greater than or equal to 8
16	greater than or equal to 16
32	greater than or equal to 32
64	greater than or equal to 64
128	greater than or equal to 128
256	greater than or equal to 256

CIU

The Card Interface Unit (CIU) interfaces with the BIU and SD/MMC cards or devices. The host processor writes command parameters to the SD/MMC controller's BIU control registers and these parameters are then passed to the CIU. Depending on control register values, the CIU generates SD/MMC command and data traffic on the card bus according to the SD/MMC protocol. The control register values also decide whether the command and data traffic is directed to the CE-ATA card, and the SD/MMC controller controls the command and data path accordingly.†

The following list describes the CIU operation restrictions:†

- After a command is issued, the CIU accepts another command only to check read status or to stop the transfer.†
- Only one data transfer command can be issued at a time.†
- During an open-ended card write operation, if the card clock is stopped because the FIFO buffer is empty, the software must first fill the data into the FIFO buffer and start the card clock. It can then issue only an SD/SDIO STOP_TRANSMISSION (CMD12) command to the card.†
- During an SDIO/COMBO card transfer, if the card function is suspended and the software wants to resume the suspended transfer, it must first reset the FIFO buffer and start the resume command as if it were a new data transfer command.†
- When issuing SD/SDIO card reset commands (GO_IDLE_STATE, GO_INACTIVE_STATE or CMD52_reset) while a card data transfer is in progress, the software must set the stop abort command bit (`stop_abort_cmd`) in the `cmd` register to 1 so that the controller can stop the data transfer after issuing the card reset command.†
- If the card clock is stopped because the FIFO buffer is full during a card read, the software must read at least two FIFO buffer locations to start the card clock.†
- If CE-ATA card device interrupts are enabled (the `nIEN` bit is set to 0 in the ATA control register), a new RW_BLK command must not be sent to the same card device if there is a pending RW_BLK command in progress (the RW_BLK command used in this document is the RW_MULTIPLE_BLOCK MMC command defined by the CE-ATA specification). Only the Command Completion Signal Disable (CCSD) command can be sent while waiting for the Command Completion Signal (CCS).†
- For the same card device, a new command is allowed for reading status information, if interrupts are disabled in the CE-ATA card (the `nIEN` bit is set to 1 in the ATA control register).†
- Open-ended transfers are not supported for the CE-ATA card devices.†
- The `send_auto_stop` signal is not supported (software must not set the `send_auto_stop` bit in the `cmd` register) for CE-ATA transfers.†

The CIU consists of the following primary functional blocks:†

- Command path†
- Data path†
- Clock control†

Command Path

The command path performs the following functions:†

- Load card command parameters†
- Send commands to card bus†
- Receive responses from card bus†
- Send responses to BIU†
- Load clock parameters†
- Drives the P-bit on command pin†

A new command is issued to the controller by writing to the BIU registers and setting the `start_cmd` bit in the `cmd` register. The command path loads the new command (command, command argument, timeout) and sends an acknowledgement to the BIU.†

After the new command is loaded, the command path state machine sends a command to the card bus—including the internally generated seven-term CRC (CRC-7)—and receives a response, if any. The state machine then sends the received response and signals to the BIU that the command is done, and then waits for eight clock cycles before loading a new command. In CE-ATA data payload transfer (RW_MULTIPLE_BLOCK) commands, if the card device interrupts are enabled (the nIEN bit is set to 0

in the ATA control register), the state machine performs the following actions after receiving the response:†

- Does not drive the P-bit; it waits for CCS, decodes and goes back to idle state, and then drives the P-bit.†
- If the host wants to send the CCSD command and if eight clock cycles are expired after the response, it sends the CCSD pattern on the command pin.†

Load Command Parameters

Commands or responses are loaded in the command path in the following situations:†

- New command from BIU—When the BIU sends a new command to the CIU, the `start_cmd` bit is set to 1 in the `cmd` register.†
- Internally-generated `send_auto_stop`—When the data path ends, the SD/SDIO STOP command request is loaded.†
- Interrupt request (IRQ) response with relative card address (RCA) 0x000—When the command path is waiting for an IRQ response from the MMC and a "send irq response" request is signaled by the BIU, the send IRQ request bit (`send_irq_response`) is set to 1 in the `ctrl` register.†

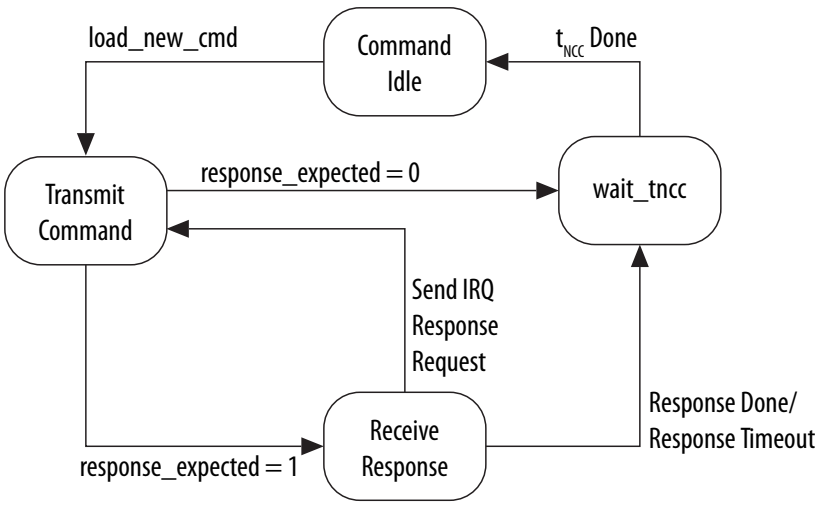
Loading a new command from the BIU in the command path depends on the following `cmd` register bit settings:†

- `update_clock_registers_only`—If this bit is set to 1 in the `cmd` register, the command path updates only the `clkena`, `clkdiv`, and `clksrc` registers. If this bit is set to 0, the command path loads the `cmd`, `cmdarg`, and `tmout` registers. It then processes the new command, which is sent to the card.†
- `wait_prvdata_complete`—If this bit is set to 1, the command path loads the new command under one of the following conditions:†
  - Immediately, if the data path is free (that is, there is no data transfer in progress), or if an open-ended data transfer is in progress (`bytcnt` = 0).†
  - After completion of the current data transfer, if a predefined data transfer is in progress.†

Send Command and Receive Response

After a new command is loaded in the command path (the `update_clock_registers_only` bit in the `cmd` register is set to 0), the command path state machine sends out a command on the card bus.†

Figure 14-6: Command Path State Machine†



The command path state machine performs the following functions, according to cmd register bit values:†

1. send_initialization—Initialization sequence of 80 clock cycles is sent before sending the command.†
2. response_expected—A response is expected for the command. After the command is sent out, the command path state machine receives a 48-bit or 136-bit response and sends it to the BIU. If the start bit of the card response is not received within the number of clock cycles (as set up in the tmout register), the rto bit and command done (CD) bit are set to 1 in the rintsts register, to signal to the BIU. If the response-expected bit is set to 0, the command path sends out a command and signals a response done to the BIU, which causes the cmd bit to be set to 1 in the rintsts register.†
3. response_length—If this bit is set to 1, a 136-bit long response is received; if it is set to 0, a 48-bit short response is received.†
4. check_response_crc—If this bit is set to 1, the command path compares CRC-7 received in the response with the internally-generated CRC-7. If the two do not match, the response CRC error is signaled to the BIU, that is, the rcrc bit is set to 1 in the rintsts register.†

Send Response to BIU

If the response_expected bit is set to 1 in the cmd register, the received response is sent to the BIU. Response register 0 (resp0) is updated for a short response, and the response register 3 (resp3), response register 2 (resp2), response register 1 (resp1), and resp0 registers are updated on a long response, after which the cmd bit is set to 1 in the rintsts register. If the response is for an AUTO_STOP command sent by the CIU, the response is written to the resp1 register, after which the auto command done bit (acd) is set to 1 in the rintsts register.†

The command path verifies the contents of the card response.

Table 14-10: Card Response Fields†

Field	Contents
Response transmission bit	0
Command index	Command index of the sent command
End bit	1

The command index is not checked for a 136-bit response or if the check_response_crc bit in the cmd register is set to 0. For a 136-bit response and reserved CRC 48-bit responses, the command index is reserved, that is, 0b111111.†

Related Information

www.sdcard.org

For more information about response values, refer to Physical Layer Simplified Specification, Version 3.01 as described on the SD Association website.

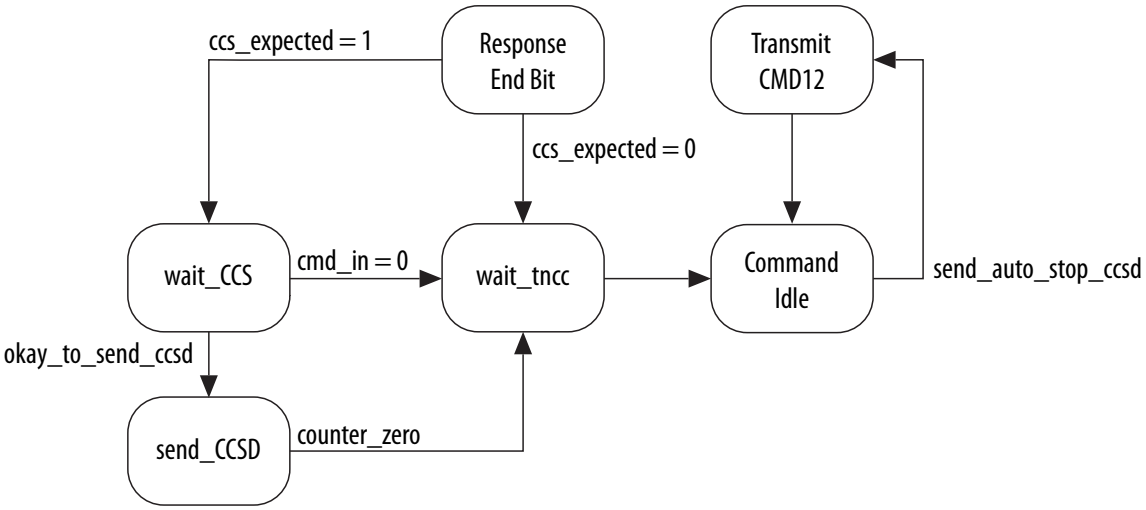
Driving P-bit to the CMD Pin

The command path drives a one-cycle pull-up bit (P-bit) to 1 on the CMD pin between two commands if a response is not expected. If a response is expected, the P-bit is driven after the response is received and before the start of the next command. While accessing a CE-ATA card device, for commands that expect a CCS, the P-bit is driven after the response only if the interrupts are disabled in the CE-ATA card (the nIEN bit is set to 1 in the ATA control register), that is, the CCS expected bit (ccs_expected) in the cmd register is set to 0. If the command expects the CCS, the P-bit is driven only after receiving the CCS.†

Polling the CCS

CE-ATA card devices generate the CCS to notify the host controller of the normal ATA command completion or ATA command termination. After receiving the response from the card, the command path state machine performs the functions illustrated in the following figure according to cmd register bit values.†

Figure 14-7: CE-ATA Command Path State Machine†



The above figure illustrates:

- Response end bit state—The state machine receives the end bit of the response from the card device. If the ccs_expected bit of the cmd register is set to 1, the state machine enters the wait CCS state.†
- Wait CCS—The state machine waits for the CCS from the CE-ATA card device. While waiting for the CCS, the following events can happen:†
  1. Software sets the send CCSD bit (send_ccsd) in the ctrl register, indicating not to wait for CCS and to send the CCSD pattern on the command line.†
  2. Receive the CCS on the CMD line.†
- Send CCSD command—Sends the CCSD pattern (0b00001) on the CMD line.†

CCS Detection and Interrupt to Host Processor

If the ccs_expected bit in the cmd register is set to 1, the CCS from the CE-ATA card device is indicated by setting the data transfer over bit (dto) in the rintsts register. The controller generates a DTO interrupt if this interrupt is not masked.†

For the RW_MULTIPLE_BLOCK commands, if the CE-ATA card device interrupts are disabled (the nIEN bit is set to 1 in the ATA control register)— that is, the ccs_expected bit is set to 0 in the cmd register—there are no CCSs from the card. When the data transfer is over—that is, when the requested number of bytes are transferred—the dto bit in the rintsts register is set to 1.†

CCS Timeout

If the command expects a CCS from the card device (the ccs_expected bit is set to 1 in the cmd register), the command state machine waits for the CCS and remains in the wait CCS state. If the CE-ATA card fails to send out the CCS, the host software must implement a timeout mechanism to free the command and

data path. The controller does not implement a hardware timer; it is the responsibility of the host software to maintain a software timer.†

In the event of a CCS timeout, the host must issue a CCSD command by setting the `send_ccsd` bit in the `ctrl` register. The controller command path state machine sends the CCSD command to the CE-ATA card device and exits to an idle state. After sending the CCSD command, the host must also send an SD/SDIO STOP_TRANSMISSION command to the CE-ATA card to abort the outstanding ATA command.†

Send CCSD Command

If the `send_ccsd` bit in the `ctrl` register is set to 1, the controller sends a CCSD pattern on the CMD line. The host can send the CCSD command while waiting for the CCS or after a CCS timeout happens.†

After sending the CCSD pattern, the controller sets the `cmd` bit in the `rintsts` register and also generates an interrupt to the host if the Command Done interrupt is not masked.†

Note: Within the CIU block, if the `send_ccsd` bit in the `ctrl` register is set to 1 on the same clock cycle as CCS is sampled, the CIU block does not send a CCSD pattern on the CMD line. In this case, the `dto` and `cmd` bits in the `rintsts` register are set to 1.†

Note: Due to asynchronous boundaries, the CCS might have already happened and the `send_ccsd` bit is set to 1. In this case, the CCSD command does not go to the CE-ATA card device and the `send_ccsd` bit is not set to 0. The host must reset the `send_ccsd` bit to 0 before the next command is issued.†

If the send auto stop CCSD (`send_auto_stop_ccsd`) bit in the `ctrl` register is set to 1, the controller sends an internally generated STOP_TRANSMISSION command (CMD12) after sending the CCSD pattern. The controller sets the `acd` bit in the `rintsts` register.†

I/O transmission delay (N_{ACIO} Timeout)

The host software maintains the timeout mechanism for handling the I/O transmission delay (N_{ACIO} cycles) time-outs while reading from the CE-ATA card device. The controller neither maintains any timeout mechanism nor indicates that N_{ACIO} cycles are elapsed while waiting for the start bit of a data token. The I/O transmission delay is applicable for read transfers using the RW_REG and RW_BLK commands; the RW_REG and RW_BLK commands used in this document refer to the RW_MULTIPLE_REGISTER and RW_MULTIPLE_BLOCK MMC commands defined by the CE-ATA specification.†

Note: After the N_{ACIO} timeout, the application must abort the command by sending the CCSD and STOP commands, or the STOP command. The Data Read Timeout (DRTO) interrupt might be set to 1 while a STOP_TRANSMISSION command is transmitted out of the controller, in which case the data read timeout boot data start bit (`bds`) and the `dto` bit in the `rintsts` register are set to 1.†

Data Path

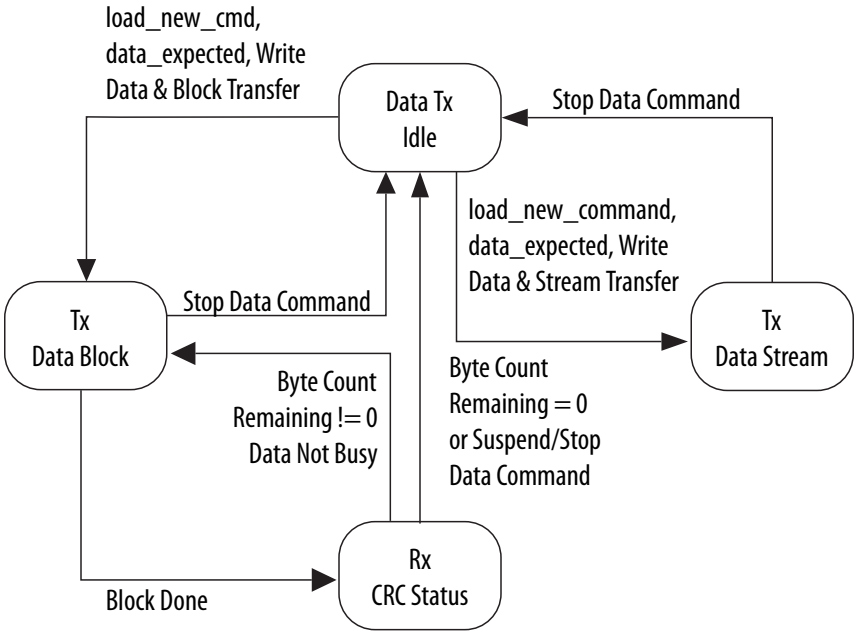
The data path block reads the data FIFO buffer and transmits data on the card bus during a write data transfer, or receives data and writes it to the FIFO buffer during a read data transfer. The data path loads new data parameters—data expected, read/write data transfer, stream/block transfer, block size, byte count, card type, timeout registers—whenever a data transfer command is not in progress. If the data transfer expected bit (`data_expected`) in the `cmd` register is set to 1, the new command is a data transfer command and the data path starts one of the following actions:†

- Transmits data if the read/write bit = 1†
- Receives data if read/write bit = 0†

Data Transmit

The data transmit state machine starts data transmission two clock cycles after a response for the data write command is received. This occurs even if the command path detects a response error or response CRC error. If a response is not received from the card because of a response timeout, data is not transmitted. Depending upon the value of the transfer mode bit (`transfer_mode`) in the `cmd` register, the data transmit state machine puts data on the card data bus in a stream or in blocks.†

Figure 14-8: Data Transmit State Machine†



Stream Data Transmit

If the `transfer_mode` bit in the `cmd` register is set to 1, the transfer is a stream-write data transfer. The data path reads data from the FIFO buffer from the BIU and transmits in a stream to the card data bus. If the FIFO buffer becomes empty, the card clock is stopped and restarted once data is available in the FIFO buffer.†

If the `bytcnt` register is reset to 0, the transfer is an open-ended stream-write data transfer. During this data transfer, the data path continuously transmits data in a stream until the host software issues an SD/SDIO STOP command. A stream data transfer is terminated when the end bit of the STOP command and end bit of the data match over two clock cycles.†

If the `bytcnt` register is written with a nonzero value and the `send_auto_stop` bit in the `cmd` register is set to 1, the STOP command is internally generated and loaded in the command path when the end bit of the STOP command occurs after the last byte of the stream write transfer matches. This data transfer can also terminate if the host issues a STOP command before all the data bytes are transferred to the card bus.†

Single Block Data

If the `transfer_mode` bit in the `cmd` register is set to 0 and the `bytcnt` register value is equal to the value of the `block_size` register, a single-block write-data transfer occurs. The data transmit state machine sends data in a single block, where the number of bytes equals the block size, including the internally-generated 16-term CRC (CRC-16).†

If the ctype register is set for a 1-bit, 4-bit, or 8-bit data transfer, the data is transmitted on 1, 4, or 8 data lines, respectively, and CRC-16 is separately generated and transmitted for 1, 4, or 8 data lines, respectively.†

After a single data block is transmitted, the data transmit state machine receives the CRC status from the card and signals a data transfer to the BIU. This happens when the dto bit in the rintsts register is set to 1.†

If a negative CRC status is received from the card, the data path signals a data CRC error to the BIU by setting the dcrc bit in the rintsts register.†

Additionally, if the start bit of the CRC status is not received by two clock cycles after the end of the data block, a CRC status start-bit error (SBE) is signaled to the BIU by setting the sbe bit in the rintsts register.†

Multiple Block Data

A multiple-block write-data transfer occurs if the transfer_mode bit in the cmd register is set to 0 and the value in the bytcnt register is not equal to the value of the block_size register. The data transmit state machine sends data in blocks, where the number of bytes in a block equals the block size, including the internally-generated CRC-16 value.†

If the ctype register is set to 1-bit, 4-bit, or 8-bit data transfer, the data is transmitted on 1, 4, or 8 data lines, respectively, and CRC-16 is separately generated and transmitted on 1, 4, or 8 data lines, respectively.†

After one data block is transmitted, the data transmit state machine receives the CRC status from the card. If the remaining byte count becomes 0, the data path signals to the BIU that the data transfer is done. This happens when the dto bit in the rintsts register is set to 1.†

If the remaining data bytes are greater than zero, the data path state machine starts to transmit another data block.†

If a negative CRC status is received from the card, the data path signals a data CRC error to the BIU by setting the dcrc bit in the rintsts register, and continues further data transmission until all the bytes are transmitted.†

If the CRC status start bit is not received by two clock cycles after the end of a data block, a CRC status SBE is signaled to the BIU by setting the ebe bit in the rintsts register and further data transfer is terminated.†

If the send_auto_stop bit is set to 1 in the cmd register, the SD/SDIO STOP command is internally generated during the transfer of the last data block, where no extra bytes are transferred to the card. The end bit of the STOP command might not exactly match the end bit of the CRC status in the last data block.†

If the block size is less than 4, 16, or 32 for card data widths of 1 bit, 4 bits, or 8 bits, respectively, the data transmit state machine terminates the data transfer when all the data is transferred, at which time the internally-generated STOP command is loaded in the command path.†

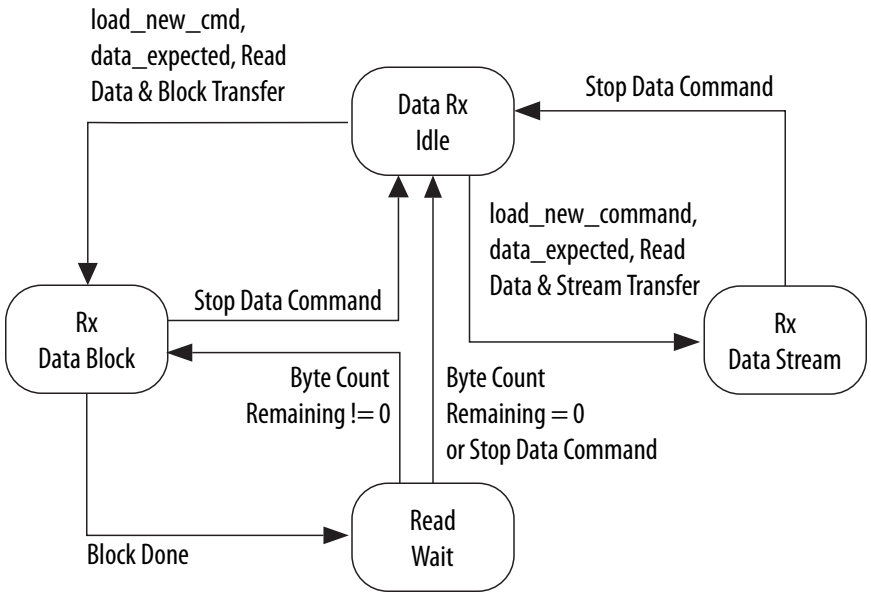
If the bytcnt is zero (the block size must be greater than zero) the transfer is an open-ended block transfer. The data transmit state machine for this type of data transfer continues the block-write data transfer until the host software issues an SD/SDIO STOP or STOP_TRANSMISSION (CMD12) command.†

Data Receive

The data-receive state machine receives data two clock cycles after the end bit of a data read command, even if the command path detects a response error or response CRC error. If a response is not received from the card because a response timeout occurs, the BIU does not receive a signal that the data transfer is complete. This happens if the command sent by the controller is an illegal operation for the card, which keeps the card from starting a read data transfer.†

If data is not received before the data timeout, the data path signals a data timeout to the BIU and an end to the data transfer done. Based on the value of the `transfer_mode` bit in the `cmd` register, the data-receive state machine gets data from the card data bus in a stream or block(s).†

Figure 14-9: Data Receive State Machine†



Stream Data Read

A stream-read data transfer occurs if the `transfer_mode` bit in the `cmd` register is set to 1, at which time the data path receives data from the card and writes it to the FIFO buffer. If the FIFO buffer becomes full, the card clock stops and restarts once the FIFO buffer is no longer full.†

An open-ended stream-read data transfer occurs if the `bytcnt` register is set to 0. During this type of data transfer, the data path continuously receives data in a stream until the host software issues an SD/SDIO STOP command. A stream data transfer terminates two clock cycles after the end bit of the STOP command.†

If the `bytcnt` register contains a nonzero value and the `send_auto_stop` bit in the `cmd` register is set to 1, a STOP command is internally generated and loaded into the command path, where the end bit of the STOP command occurs after the last byte of the stream data transfer is received. This data transfer can terminate if the host issues an SD/SDIO STOP or STOP_TRANSMISSION (CMD12) command before all the data bytes are received from the card.†

Single-block Data Read

If the `ctype` register is set to a 1-bit, 4-bit, or 8-bit data transfer, data is received from 1, 4, or 8 data lines, respectively, and CRC-16 is separately generated and checked for 1, 4, or 8 data lines, respectively. If there

is a CRC-16 mismatch, the data path signals a data CRC error to the BIU. If the received end bit is not 1, the BIU receives an End-bit Error (EBE).†

Multiple-block Data Read

If the `transfer_mode` bit in the `cmd` register is clear and the value of the `bytcnt` register is not equal to the value of the `block_size` register, the transfer is a multiple-block read-data transfer. The data-receive state machine receives data in blocks, where the number of bytes in a block is equal to the block size, including the internally-generated CRC-16.†

If the `ctype` register is set to a 1-bit, 4-bit, or 8-bit data transfer, data is received from 1, 4, or 8 data lines, respectively, and CRC-16 is separately generated and checked for 1, 4, or 8 data lines, respectively. After a data block is received, if the remaining byte count becomes zero, the data path signals a data transfer to the BIU.†

If the remaining data bytes are greater than zero, the data path state machine causes another data block to be received. If CRC-16 of a received data block does not match the internally-generated CRC-16, a data CRC error to the BIU and data reception continue further data transmission until all bytes are transmitted. Additionally, if the end of a received data block is not 1, data on the data path signals terminate the bit error to the CIU and the data-receive state machine terminates data reception, waits for data timeout, and signals to the BIU that the data transfer is complete.†

If the `send_auto_stop` bit in the `cmd` register is set to 1, the SD/SDIO STOP command is internally generated when the last data block is transferred, where no extra bytes are transferred from the card. The end bit of the STOP command might not exactly match the end bit of the last data block.†

If the requested block size for data transfers to cards is less than 4, 16, or 32 bytes for 1-bit, 4-bit, or 8-bit data transfer modes, respectively, the data-transmit state machine terminates the data transfer when all data is transferred, at which point the internally-generated STOP command is loaded in the command path. Data received from the card after that are then ignored by the data path.†

If the `bytcnt` register is 0 (the block size must be greater than zero), the transfer is an open-ended block transfer. For this type of data transfer, the data-receive state machine continues the block-read data transfer until the host software issues an SD/SDIO STOP or STOP_TRANSMISSION (CMD12) command.†

Auto-Stop

The controller internally generates an SD/SDIO STOP command and is loaded in the command path when the `send_auto_stop` bit in the `cmd` register is set to 1. The AUTO_STOP command helps to send an exact number of data bytes using a stream read or write for the MMC, and a multiple-block read or write for SD memory transfer for SD cards. The software must set the `send_auto_stop` bit according to the following details: †

The following list describes conditions for the AUTO_STOP command:†

- Stream-read for MMC with byte count greater than zero—The controller generates an internal STOP command and loads it into the command path so that the end bit of the STOP command is sent when the last byte of data is read from the card and no extra data byte is received. If the byte count is less than six (48 bits), a few extra data bytes are received from the card before the end bit of the STOP command is sent.†
- Stream-write for MMC with byte count greater than zero—The controller generates an internal STOP command and loads it into the command path so that the end bit of the STOP command is sent when the last byte of data is transmitted on the card bus and no extra data byte is transmitted. If the byte count is less than six (48 bits), the data path transmits the data last to meet these condition.†
- Multiple-block read memory for SD card with byte count greater than zero—If the block size is less than four (single-bit data bus), 16 (4-bit data bus), or 32 (8-bit data bus), the AUTO_STOP command is loaded in the command path after all the bytes are read. Otherwise, the STOP command is loaded in the command path so that the end bit of the STOP command is sent after the last data block is received.†
- Multiple-block write memory for SD card with byte count greater than zero—If the block size is less than three (single-bit data bus), 12 (4-bit data bus), or 24 (8-bit data bus), the AUTO_STOP command is loaded in the command path after all data blocks are transmitted. Otherwise, the STOP command is loaded in the command path so that the end bit of the STOP command is sent after the end bit of the CRC status is received.†
- Precaution for host software during auto-stop—When an AUTO_STOP command is issued, the host software must not issue a new command to the controller until the AUTO_STOP command is sent by the controller and the data transfer is complete. If the host issues a new command during a data transfer with the AUTO_STOP command in progress, an AUTO_STOP command might be sent after the new command is sent and its response is received. This can delay sending the STOP command, which transfers extra data bytes. For a stream write, extra data bytes are erroneous data that can corrupt the card data. If the host wants to terminate the data transfer before the data transfer is complete, it can issue an SD/SDIO STOP or STOP_TRANSMISSION (CMD12) command, in which case the controller does not generate an AUTO_STOP command.†

Auto-Stop Generation for MMC Cards

Table 14-11: Auto-Stop Generation for MMC Cards†

Transfer Type	Byte Count	send_auto_stop bit set	Comments
Stream read	0	No	Open-ended stream
Stream read	>0	Yes	Auto-stop after all bytes transfer
Stream write	0	No	Open-ended stream
Stream write	>0	Yes	Auto-stop after all bytes transfer
Single-block read	>0	No	Byte count = 0 is illegal
Single-block write	>0	No	Byte count = 0 is illegal
Multiple-block read	0	No	Open-ended multiple block
Multiple-block read	>0	Yes †	Pre-defined multiple block
Multiple-block write	0	No	Open-ended multiple block
Multiple-block write	>0	Yes †	Pre-defined multiple block

Auto-Stop Generation for SD Cards

Table 14-12: Auto-Stop Generation for SD Cards†

Transfer Type	Byte Count	send_auto_stop bit set	Comments
Single-block read	>0	No	Byte count = 0 is illegal
Single-block write	>0	No	Byte count = 0 illegal
Multiple-block read	0	No	Open-ended multiple block
Multiple-block read	>0	Yes	Auto-stop after all bytes transfer
Multiple-block write	0	No	Open-ended multiple block
Multiple-block write	>0	Yes	Auto-stop after all bytes transfer

Auto-Stop Generation for SDIO Cards

Transfer Type	Byte Count	send_auto_stop bit set	Comments
Single-block read	>0	No	Byte count = 0 is illegal
Single-block write	>0	No	Byte count = 0 illegal
Multiple-block read	0	No	Open-ended multiple block
Multiple-block read	>0	No	Pre-defined multiple block
Multiple-block write	0	No	Open-ended multiple block
Multiple-block write	>0	No	Pre-defined multiple block

Non-Data Transfer Commands that Use Data Path

Some SD/SDIO non-data transfer commands (commands other than read and write commands) also use the data path.†

(41) The condition under which the transfer mode is set to block transfer and byte_count is equal to block size is treated as a single-block data transfer command for both MMC and SD cards. If byte_count = n*block_size (n = 2, 3, …), the condition is treated as a predefined multiple-block data transfer command. In the case of an MMC card, the host software can perform a predefined data transfer in two ways: 1) Issue the CMD23 command before issuing CMD18/CMD25 commands to the card – in this case, issue CMD18/CMD25 commands without setting the send_auto_stop bit. 2) Issue CMD18/CMD25 commands without issuing CMD23 command to the card, with the send_auto_stop bit set. In this case, the multiple-block data transfer is terminated by an internally-generated auto-stop command after the programmed byte count.†

Clock Control Block

The clock control block provides different clock frequencies required for SD/MMC/CE-ATA cards. The clock control block has one clock divider, which is used to generate different card clock frequencies.†

The clock frequency of a card depends on the following clock `ctrl` register settings:†

- `clkdiv` register—Internal clock dividers are used to generate different clock frequencies required for the cards. The division factor for the clock divider can be set by writing to the `clkdiv` register. The clock divider is an 8-bit value that provides a clock division factor from 1 to 510; a value of 0 represents a clock-divider bypass, a value of 1 represents a divide by 2, a value of 2 represents a divide by 4, and so on.†
- `clksrc` register—Set this register to 0 as clock is divided by clock divider 0.†
- `clkena` register—The `cclk_out` card output clock can be enabled or disabled under the following conditions:†
  - `cclk_out` is enabled when the `cclk_enable` bit in the `clkena` register is set to 1 and disabled when set to 0.†
  - Low-power mode can be enabled by setting the `cclk_low_power` bit of the `clkena` register to 1. If low-power mode is enabled to save card power, the `cclk_out` signal is disabled when the card is idle for at least eight card clock cycles. Low-power mode is enabled when a new command is loaded and the command path goes to a non-idle state.†

Under the following conditions, the card clock is stopped or disabled:†

- Clock can be disabled by writing to the `clkena` register.†
- When low-power mode is selected and the card is idle for at least eight clock cycles.†
- FIFO buffer is full, data path cannot accept more data from the card, and data transfer is incomplete—to avoid FIFO buffer overflow.†
- FIFO buffer is empty, data path cannot transmit more data to the card, and data transfer is incomplete —to avoid FIFO buffer underflow.†

(42) Num_bytes = Number of bytes specified as per the lock card data structure. Refer to the SD specification and the MMC specification.

(43) Num_bytes = Number of bytes specified as per the lock card data structure. Refer to the SD specification and the MMC specification.

Note: The card clock must be disabled through the `clkena` register before the host software changes the values of the `clkdiv` and `clksrc` registers.†

Error Detection

Errors can occur during card operations within the CIU in the following situations.

Response†

- Response timeout—did not receive the response expected with response start bit within the specified number of clock cycles in the timeout register.†
- Response CRC error—response is expected and check response CRC requested; response CRC-7 does not match with the internally-generated CRC-7.†
- Response error—response transmission bit is not 0, command index does not match with the command index of the send command, or response end bit is not 1.†

Data Transmit†

- No CRC status—during a write data transfer, if the CRC status start bit is not received for two clock cycles after the end bit of the data block is sent out, the data path performs the following actions:†
  - Signals no CRC status error to the BIU†
  - Terminates further data transfer†
  - Signals data transfer done to the BIU†
- Negative CRC—if the CRC status received after the write data block is negative (that is, not 0b010), the data path signals a data CRC error to the BIU and continues with the data transfer.†
- Data starvation due to empty FIFO buffer—if the FIFO buffer becomes empty during a write data transmission, or if the card clock stopped and the FIFO buffer remains empty for a data-timeout number of clock cycles, the data path signals a data-starvation error to the BIU and the data path continues to wait for data in the FIFO buffer.†

Data Receive

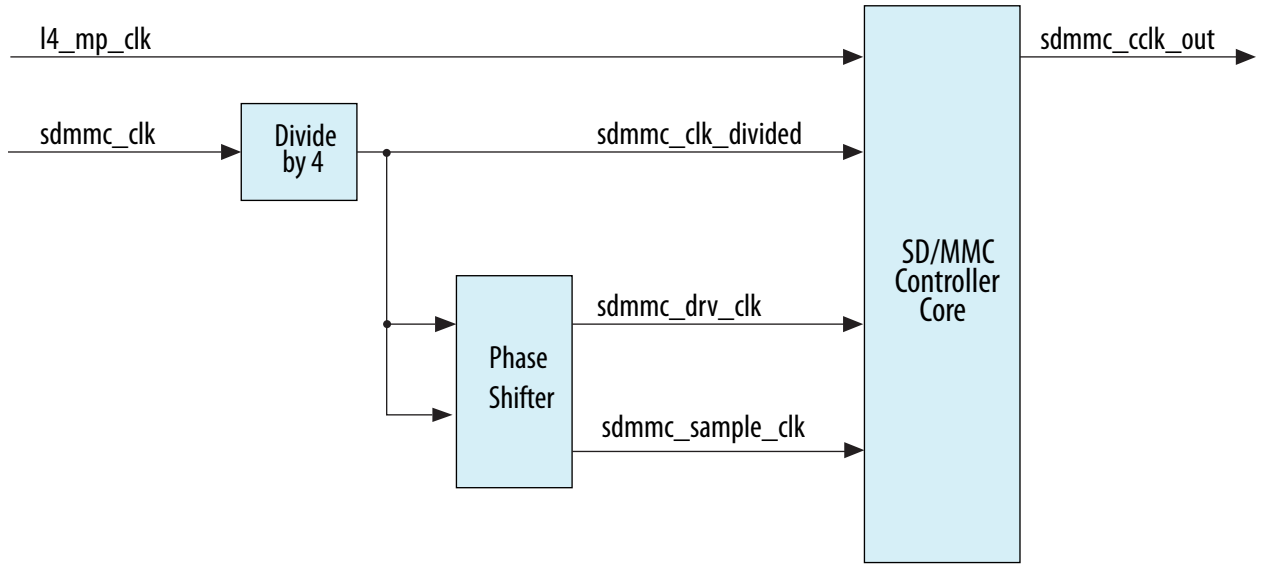
- Data timeout—during a read-data transfer, if the data start bit is not received before the number of clock cycles specified in the timeout register, the data path does the following action: †
  - Signals a data-timeout error to the BIU†
  - Terminates further data transfer†
  - Signals data transfer done to BIU†
- Data SBE—during a 4-bit or 8-bit read-data transfer, if the all-bit data line does not have a start bit, the data path signals a data SBE to the BIU and waits for a data timeout, after which it signals that the data transfer is done.†
- Data CRC error—during a read-data-block transfer, if the CRC-16 received does not match with the internally generated CRC-16, the data path signals a data CRC error to the BIU and continues with the data transfer.†
- Data EBE—during a read-data transfer, if the end bit of the received data is not 1, the data path signals an EBE to the BIU, terminates further data transfer, and signals to the BIU that the data transfer is done.†
- Data starvation due to FIFO buffer full—during a read data transmission and when the FIFO buffer becomes full, the card clock stops. If the FIFO buffer remains full for a data-timeout number of clock cycles, the data path signals a data starvation error to the BIU, by setting the data starvation host timeout bit (`hto`) in `rintsts` register to 1, and the data path continues to wait for the FIFO buffer to empty.†

Clocks

Table 14-18: SD/MMC Controller Clocks

Clock Name	Direction	Description
l4_mp_clk	In	Clock for SD/MMC controller BIU
sdmmc_clk	In	Clock for SD/MMC controller
sdmmc_cclk_out	Out	Generated output clock for card
sdmmc_clk_divided	Internal	Divide-by-four clock of sdmmc_clk
sdmmc_sample_clk	Internal	Phase-shifted clock of sdmmc_clk_divided used to sample the command and data from the card
sdmmc_drv_clk	Internal	Phase-shifted clock of sdmmc_clk_divided for controller to drive command and data to the card to meet hold time requirements

Figure 14-10: SD/MMC Controller Clock Connections



The *sdmmc_clk* clock from the clock manager is divided by four and becomes the *sdmmc_clk_divided* clock before passing to the phase shifters and the SD/MMC controller CIU. The phase shifters are used to generate the *sdmmc_drv_clk* and *sdmmc_sample_clk* clocks. These phase shifters provide up to eight phases shift which include 0, 45, 90, 135, 180, 225, 270, and 315 degrees. The *sdmmc_sample_clk* clock can be driven by the output from the phase shifter.

Note: The selections of phase shift degree and *sdmmc_sample_clk* source are done in the system manager. For information about setting the phase shift and selecting the source of the *sdmmc_sample_clk* clock, refer to the *Clock Setup* section within this document.

The controller generates the *sdmmc_cclk_out* clock, which is driven to the card. For more information about the generation of the *sdmmc_cclk_out* clock, refer to the *Clock Control Block* section within this document.

Resets

The SD/MMC controller has one reset signal. The reset manager drives this signal to the SD/MMC controller on a cold or warm reset.

Related Information

Reset Manager on page 3-1

Taking the SD/MMC Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the MPU boots up, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

Voltage Switching

This section describes the general steps to switch voltage level.

The SD/MMC cards support various operating voltages, for example 1.8V and 3.3V. If you have a card which is at 1.8V and you eject it and replace it with another card, which is 3.3V, then voltage switching is required.

In order to have the right voltage level to power the card, separate devices on the board are required: voltage translation transceiver and power regulator/supply. When the software is aware that voltage switching is needed, it notifies the power regulator that it needs to supply another voltage level to the card (i.e. switching between 1.8V and 3.3V).

Many SD cards have an option to signal at 1.8 or 3.3 V, however the initial power-up voltage requirement is 3.3V. To support these different voltage requirements, external transceivers are needed.

The general steps to switch voltage level requires you to use a SD/MMC voltage-translation transceiver in between the HPS and the SD/MMC card.

1. Power the HPS I/O pins for the SD/MMC controller to 3.3V.

   Connect the same power supply to one of the transceiver voltage input pins.
2. Power the other transceiver voltage input pin with another power supply.

   Connect this power supply with the SD/MMC card.
3. The SD/MMC will send predefined commands to check whether the card supports dual voltage.

   Note: During this transaction, the software stops all SD/MMC activity.

   The response from the card indicates whether dual voltage is supported.

Note: If the card does not support dual voltage, do not perform the remaining steps; otherwise, continue to the next step.

4. Send a command to indicate that you want to switch to 1.8 V.

   Then the GPIO on HPS sends a signal to the external power supply on the board notifying it to switch its voltage value.
5. After voltage switching is completed, resume the SD/MMC activity.

Interface Signals

The following table shows the SD/MMC controller signals when they are routed to the FPGA instead of the HPS I/O pin multiplexer.

Note: The last five signals in the table are not routed to HPS I/O, but only to the FPGA.

Table 14-19: SD/MMC Controller Interface I/O Pins

Signal	Width	Direction	Description
sdmmc_cclk_out	1	Out	Clock from controller to the card
sdmmc_cmd	1	In/Out	Card command
sdmmc_pwren	1	Out	External device power enable
sdmmc_data	8	In/Out	Card data
sdmmc_cdn_i	1	In	Card detect signal
sdmmc_wp_i	1	In	Card write protect signal
sdmmc_vs_o	1	Out	Voltage switching between 3.3V and 1.8V
sdmmc_rstn_o	1	Out	Card reset signal
sdmmc_card_intn_i	1	In	Cad interrupt signal

SD/MMC Controller Programming Model

Software and Hardware Restrictions†

Only one data transfer command should be issued at one time. For CE-ATA devices, if CE-ATA device interrupts are enabled (nIEN=0), only one RW_MULTIPLE_BLOCK command (RW_BLK) should be issued; no other commands (including a new RW_BLK) should be issued before the Data Transfer Over status is set for the outstanding RW_BLK.†

Before issuing a new data transfer command, the software should ensure that the card is not busy due to any previous data transfer command. Before changing the card clock frequency, the software must ensure that there are no data or command transfers in progress.†

If the card is enumerated in SDR12 or SDR25 mode, the application must program the use_hold_reg bit[29] in the CMD register to 1'b1.†

This programming should be done for all data transfer commands and non-data commands that are sent to the card. When the use_hold_reg bit is programmed to 1'b0, the SD/MMC controller bypasses the Hold Registers in the transmit path. The value of this bit should not be changed when a Command or Data Transfer is in progress.†

For more information on using the `use_hold_reg` and the implementation requirements for meeting the card input hold time, refer to the latest version of the Synopsys DesignWare Cores Mobile Storage Host Databook.

Avoiding Glitches in the Card Clock Outputs†

To avoid glitches in the card clock outputs (`sdmmc_cclk_out`), the software should use the following steps when changing the card clock frequency:†

1. Before disabling the clocks, ensure that the card is not busy due to any previous data command. To determine this, check for 0 in bit 9 of the STATUS register.†
2. Update the Clock Enable register to disable all clocks. To ensure completion of any previous command before this update, send a command to the CIU to update the clock registers by setting:†
   - `start_cmd` bit†
   - "update clock registers only" bits†
   - "wait_previous data complete"†

   Note: Wait for the CIU to take the command by polling for 0 on the `start_cmd` bit.†
3. Set the `start_cmd` bit to update the Clock Divider and/or Clock Source registers, and send a command to the CIU in order to update the clock registers; wait for the CIU to take the command.†
4. Set `start_cmd` to update the Clock Enable register in order to enable the required clocks and send a command to the CIU to update the clock registers; wait for the CIU to take the command.†

Reading from a Card in Non-DMA Mode†

In non-DMA mode, while reading from a card, the Data Transfer Over (RINTSTS[3]) interrupt occurs as soon as the data transfer from the card is over. There still could be some data left in the FIFO, and the RX_WMark interrupt may or may not occur, depending on the remaining bytes in the FIFO. Software should read any remaining bytes upon seeing the Data Transfer Over (DTO) interrupt. While using the external DMA interface for reading from a card, the DTO interrupt occurs only after all the data is flushed to memory by the DMA Interface unit.†

Writing to a Card in External DMA Mode†

While writing to a card in external DMA mode, if an undefined-length transfer is selected by setting the Byte Count register to 0, the DMA logic will likely request more data than it will send to the card, since it has no way of knowing at which point the software will stop the transfer. The DMA request stops as soon as the DTO is set by the CIU.†

Software Issues a Controller_Reset Command†

If the software issues a controller_reset command by setting control register bit[0] to 1, all the CIU state machines are reset; the FIFO is not cleared. The DMA sends all remaining bytes to the host. In addition to a card-reset, if a FIFO reset is also issued, then:†

- Any pending DMA transfer on the bus completes correctly†
- DMA data read is ignored†
- Write data is unknown (x)†

Additionally, if dma_reset is also issued, any pending DMA transfer is abruptly terminated. When the DW-DMA/Non-DW-DMA is used, the DMA controller channel should also be reset and reprogrammed.†

If any of the previous data commands do not properly terminate, then the software should issue the FIFO reset in order to remove any residual data, if any, in the FIFO. After asserting the FIFO reset, you should wait until this bit is cleared.†

Data-Transfer Requirement Between the FIFO and Host†

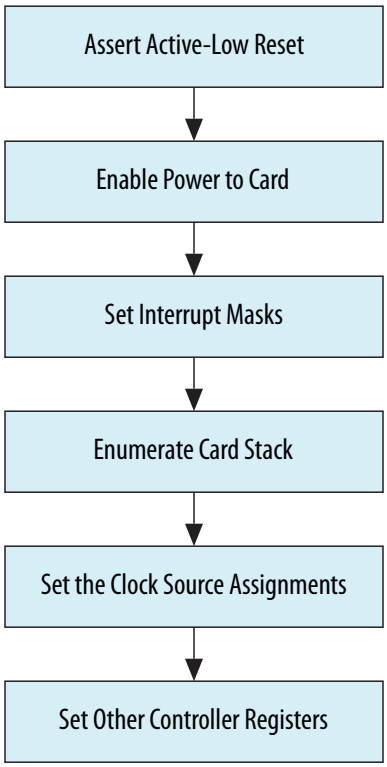
One data-transfer requirement between the FIFO and host is that the number of transfers should be a multiple of the FIFO data width (F_DATA_WIDTH). For example, if F_DATA_WIDTH = 32 and you want to write only 15 bytes to an SD_MMC_CEATA card (BYTCNT), the host should write 16 bytes to the FIFO or program the DMA to do 16-byte transfers, if external DMA mode is enabled. The software can still program the Byte Count register to only 15, at which point only 15 bytes will be transferred to the card. Similarly, when 15 bytes are read from a card, the host should still read all 16 bytes from the FIFO.†

It is recommended that you not change the FIFO threshold register in the middle of data transfers when DW-DMA/Non-DW-DMA mode is chosen.†

Initialization†

After the power and clock to the controller are stable, the controller active-low reset is asserted. The reset sequence initializes the registers, FIFO buffer pointers, DMA interface controls, and state machines in the controller.†

Figure 14-11: SD/MMC Controller Initialization Sequence†



Power-On Reset Sequence

Software must perform the following steps after the power-on-reset:

1. Before enabling power to the card, confirm that the voltage setting to the voltage regulator is correct. †
2. Enable power to the card by setting the power enable bit (`power_enable`) in the power enable register (`pwren`) to 1. Wait for the power ramp-up time before proceeding to the next step.†
3. Set the interrupt masks by resetting the appropriate bits to 0 in the `intmask` register.†
4. Set the `int_enable` bit of the `ctrl` register to 1.†

   Note: Altera recommends that you write 0xFFFFFFFF to the `rintsts` register to clear any pending interrupts before setting the `int_enable` bit to 1.†
5. Discover the card stack according to the card type. For discovery, you must restrict the clock frequency to 400 kHz in accordance with SD/MMC/CE-ATA standards. For more information, refer to *Enumerated Card Stack*.†
6. Set the clock source assignments. Set the card frequency using the `clkdiv` and `clksrc` registers of the controller. For more information, refer to *Clock Setup*.†
7. The following common registers and fields can be set during initialization process:†

- The response timeout field (`response_timeout`) of the `tmout` register. A typical value is `0x40`.†
- The data timeout field (`data_timeout`) of the `tmout` register, highest of the following:†
  - $10 * N_{AC}$ †

    N_{AC} = card device total access time†

    = $10 * ((TAAC * F_{OP}) + (100 * NSAC))$†

    where:†

    TAAC = Time-dependent factor of the data access time†

    F_{OP} = The card clock frequency used for the card operation†

    NSAC = Worst-case clock rate-dependent factor of the data access time†
  - Host FIFO buffer latency†

    On read: Time elapsed before host starts reading from a full FIFO buffer†

    On write: Time elapsed before host starts writing to an empty FIFO buffer†
- Debounce counter register (`debnce`). A typical debounce value is 25 ms.†
- TX watermark field (`tx_wmark`) of the FIFO threshold watermark register (`fifoth`). Typically, the threshold value is set to 512, which is half the FIFO buffer depth.†
- RX watermark field (`rx_wmark`) of the `fifoth` register. Typically, the threshold value is set to 511.†

These registers do not need to be changed with every SD/MMC/CE-ATA command. Set them to a typical value according to the SD/MMC/CE-ATA specifications.

Related Information

- **Clock Setup** on page 14-43
  Refer to this section for information on setting the clock source assignments.
- **Enumerated Card Stack** on page 14-40
  Refer to this section for information on discovering the card stack according to the card type.

Enumerated Card Stack

The card stack performs the following tasks:

- Discovers the connected card †
- Sets the relative Card Address Register (RCA) in the connected card†
- Reads the card specific information†
- Stores the card specific information locally†

The card connected to the controller can be an MMC, CE-ATA, SD or SDIO (including IO ONLY, MEM ONLY and COMBO) card.

Identifying the Connected Card Type

To identify the connected card type, the following discovery sequence is needed:

1. Reset the card width 1 or 4 bit (`card_width2`) and card width 8 bit (`card_width1`) fields in the `ctype` register to 0.
2. Identify the card type as SD, MMC, SDIO or SDIO-COMBO:

a. Send an SD/SDIO IO_SEND_OP_COND (CMD5) command with argument 0 to the card.
b. Read resp0 on the controller. The response to the IO_SEND_OP_COND command gives the voltage that the card supports.
c. Send the IO_SEND_OP_COND command, with the desired voltage window in the arguments. This command sets the voltage window and makes the card exit the initialization state.
d. Check bit 27 in resp0:

- If bit 27 is 0, the SDIO card is IO ONLY. In this case, proceed to **step 5**.
- If bit 27 is 1, the card type is SDIO COMBO. Continue with the following steps.

3. Go to **Card Type is Either SDIO COMBO or Still in Initialization** on page 14-41.
4. Go to **Determine if Card is a CE-ATA 1.1, CE-ATA 1.0, or MMC Device** on page 14-42.
5. At this point, the software has determined the card type as SD/SDHC, SDIO or SDIO-COMBO. Now it must enumerate the card stack according to the type that has been discovered.
6. Set the card clock source frequency to the frequency of identification clock rate, 400 KHz. Use one of the following discovery command sequences:
   - For an SD card or an SDIO memory section, send the following SD/SDIO command sequence:
     - GO_IDLE_STATE
     - SEND_IF_COND
     - SD_SEND_OP_COND (ACMD41)
     - ALL_SEND_CID (CMD2)
     - SEND_RELATIVE_ADDR (CMD3)
   - For an SDIO card, send the following command sequence:
     - IO_SEND_OP_COND
     - If the function count is valid, send the SEND_RELATIVE_ADDR command.
   - For an MMC, send the following command sequence:
     - GO_IDLE_STATE
     - SEND_OP_COND (CMD1)
     - ALL_SEND_CID
     - SEND_RELATIVE_ADDR
7. You can change the card clock frequency after discovery by writing a value to the clkdiv register that divides down the sdmmc_clk clock.

   The following list shows typical clock frequencies for various types of cards:

   - SD memory card, 25 MHz†
   - MMC card device, 12.5 MHz†
   - Full speed SDIO, 25 MHz†
   - Low speed SDIO, 400 kHz†

Related Information

www.sdcard.org
To learn more about how SD technology works, visit the SD Association website.

Card Type is Either SDIO COMBO or Still in Initialization

Only continue with this step if the SDIO card type is COMBO or there is no response received from the previous IO_SEND_OP_COND command. Otherwise, skip to **step 5** of the *Identifying the Connected Card Type* section.

1. Send the SD/SDIO SEND_IF_COND (CMD8) command with the following arguments:

- Bit[31:12] = 0x0 (reserved bits)†
- Bit[11:8] = 0x1 (supply voltage value)†
- Bit[7:0] = 0xAA (preferred check pattern by SD memory cards compliant with SDIO Simplified Specification Version 2.00 and later.)†

Refer to *SDIO Simplified Specification Version 2.00* as described on the SD Association website.

- If a response is received to the previous SEND_IF_COND command, the card supports SD High-Capacity, compliant with *SD Specifications, Part 1, Physical Layer Simplified Specification Version 2.00*.
- If no response is received, proceed to **the next decision statement**.

2. Send the SD_SEND_OP_COND (ACMD41) command with the following arguments:

- Bit[31] = 0x0 (reserved bits)†
- Bit[30] = 0x1 (high capacity status)†
- Bit[29:25] = 0x0 (reserved bits)†
- Bit[24] = 0x1 (S18R --supports voltage switching for 1.8V)†
- Bit[23:0] = supported voltage range†

- If the previous SD_SEND_OP_COND command receives a response, then the card type is SDHC. Otherwise, the card is MMC or CE-ATA. In either case, skip the following steps and proceed to **step 5** of the "Identifying the Connected Card Type" section.
- If the initial SEND_IF_COND command does not receive a response, then the card does not support High Capacity SD2.0. Now, proceed to **step step 3**.

3. Next, issue the GO_IDLE_STATE command followed by the SD_SEND_OP_COND command with the following arguments:

- Bit[31] = 0x0 (reserved bits)†
- Bit[30] = 0x0 (high capacity status)†
- Bit[29:24] = 0x0 (reserved bits)†
- Bit[23:0] = supported voltage range†

If a response is received to the previous SD_SEND_OP_COND command, the card is SD type. Otherwise, the card is MMC or CE-ATA.

Note: You must issue the SEND_IF_COND command prior to the first SD_SEND_OP_COND command, to initialize the High Capacity SD memory card. The card returns busy as a response to the SD_SEND_OP_COND command when any of the following conditions are true:

- The card executes its internal initialization process.
- A SEND_IF_COND command is not issued before the SD_SEND_OP_COND command.
- The ACMD41 command is issued. In the command argument, the Host Capacity Support (HCS) bit is set to 0, for a high capacity SD card.

Determine if Card is a CE-ATA 1.1, CE-ATA 1.0, or MMC Device

Use the following sequence to determine whether the card is a CE-ATA 1.1, CE-ATA 1.0, or MMC device:

Determine whether the card is a CE-ATA v1.1 card device by attempting to select ATA mode.

1. Send the SD/SDIO SEND_IF_COND command, querying byte 504 (S_CMD_SET) of the EXT_CSD register block in the external card.

If bit 4 is set to 1, the card device supports ATA mode.

2. Send the `SWITCH_FUNC (CMD6)` command, setting the ATA bit (bit 4) of the EXT_CSD register slice 191 (CMD_SET) to 1.

   This command selects ATA mode and activates the ATA command set.
3. You can verify the currently selected mode by reading it back from byte 191 of the EXT_CSD register.
4. Skip to **step 5** of the *Identifying the Connected Card Type* section.

   If the card device does not support ATA mode, it might be an MMC card or a CE-ATA v1.0 card. Proceed to the **next section** to determine whether the card is a CE-ATA 1.0 card device or an MMC card device.

Determine whether the card is a CE-ATA 1.0 card device or an MMC card device by sending the RW_REG command.

If a response is received and the response data contains the CE-ATA signature, the card is a CE-ATA 1.0 card device. Otherwise, the card is an MMC card device.

Clock Setup

The following registers of the SD/MMC controller allow software to select the desired clock frequency for the card:

- `clksrc`
- `clkdiv`
- `clkena`

The controller loads these registers when it receives an update clocks command.

Changing the Card Clock Frequency

To change the card clock frequency, perform the following steps:

1. Before disabling the clocks, ensure that the card is not busy with any previous data command. To do so, verify that the `data_busy` bit of the status register (`status`) is 0.
2. Reset the `cclk_enable` bit of the `clkena` register to 0, to disable the card clock generation.
3. Reset the `clksrc` register to 0.
4. Set the following bits in the `cmd` register to 1:
   - `update_clk_regs_only`—Specifies the update clocks command†
   - `wait_prvdata_complete`—Ensures that clock parameters do not change until any ongoing data transfer is complete†
   - `start_cmd`—Initiates the command†
5. Wait until the `start_cmd` and `update_clk_regs_only` bits change to 0. There is no interrupt when the clock modification completes. The controller does not set the `command_done` bit in the `rintsts` register upon command completion. The controller might signal a hardware lock error if it already has another command in the queue. In this case, return to **Step 4**.

   For information about hardware lock errors, refer to *Interrupt and Error Handling*.
6. Reset the `sdmmc_clk_enable` bit to 0 in the `enable` register of the clock manager peripheral PLL group (`perpllgrp`).
7. In the control register (`ctrl`) of the SDMMC controller group (`sdmmcgrp`) in the system manager, set the drive clock phase shift select (`drvsel`) and sample clock phase shift select (`smplsel`) bits to specify the required phase shift value.
8. Set the `sdmmc_clk_enable` bit in the `Enable` register of the clock manager `perpllgrp` group to 1.
9. Set the `clkdiv` register of the controller to the correct divider value for the required clock frequency.
10. Set the `cclk_enable` bit of the `clkena` register to 1, to enable the card clock generation.

You can also use the clkena register to enable low-power mode, which automatically stops the sdmmc_cclk_out clock when the card is idle for more than eight clock cycles.

Interrupt and Error Handling on page 14-70
Refer to this section for information about hardware lock errors.

Controller/DMA/FIFO Buffer Reset Usage

The following list shows the effect of reset on various parts in the SD/MMC controller:†

- Controller reset—resets the controller by setting the controller_reset bit in the ctrl register to 1. Controller reset resets the CIU and state machines, and also resets the BIU-to-CIU interface. Because this reset bit is self-clearing, after issuing the reset, wait until this bit changes to 0.†
- FIFO buffer reset—resets the FIFO buffer by setting the FIFO reset bit (fifo_reset) in the ctrl register to 1. FIFO buffer reset resets the FIFO buffer pointers and counters in the FIFO buffer. Because this reset bit is self-clearing, after issuing the reset, wait until this bit changes to 0.†
- DMA reset—resets the internal DMA controller logic by setting the DMA reset bit (dma_reset) in the ctrl register to 1, which immediately terminates any DMA transfer in progress. Because this reset bit is self-clearing, after issuing the reset, wait until this bit changes to 0.†

Note: Ensure that the DMA is idle before performing a DMA reset. Otherwise, the L3 interconnect might be left in an indeterminate state.†

Altera recommends setting the controller_reset, fifo_reset, and dma_reset bits in the ctrl register to 1 first, and then resetting the rintsts register to 0 using another write, to clear any resultant interrupt.

Enabling FIFO Buffer ECC

To protect the FIFO buffer data with ECC, you must enable the ECC feature before performing any operations with the SD/MMC controller. Perform the following steps to enable the FIFO buffer ECC feature:

1. Verify there are no commands committed to the controller.
2. Ensure that the FIFO buffer is initialized. Initialize the FIFO buffer by writing 0 to all 1024 FIFO buffer locations. A FIFO buffer write to any address from 0x200 to the maximum FIFO buffer size is valid.
3. Set the SDMMC RAM ECC single and double, correctable error interrupt status bits (serrporta, derrporta, serrportb, and derrportb) to 1 in the sdmmc register in the eccgrp group of the system manager, to clear any previously-detected ECC errors.
4. Reset the FIFO buffer by setting the fifo_reset bit to 1 in the ctrl register. This action resets pointers and counters in the FIFO buffer. This reset bit is self-clearing, so after issuing the reset, wait until the bit changes to 0.
5. Set the en bit in sdmmc register in eccgrp group of the system manager to 1, to enable ECC for the FIFO buffer in SD/MMC controller.

Non-Data Transfer Commands

To send any non-data transfer command, the software needs to write the cmd register and the cmdarg register with appropriate parameters. Using these two registers, the controller forms the command and sends it to the CMD pin. The controller reports errors in the command response through the error bits of the rintsts register.†

When a response is received—either erroneous or valid—the controller sets the command_done bit in the rintsts register to 1. A short response is copied to resp0, while a long response is copied to all four

response registers (resp0, resp1, resp2, and resp3).† For long responses, bit 31 of resp3 represents the MSB and bit 0 of resp0 represents the LSB.†

For basic and non-data transfer commands, perform the following steps:

1. Write the cmdarg register with the appropriate command argument parameter.†
2. Write the cmd register with the settings in *Register Settings for Non-Data Transfer Command*.†
3. Wait for the controller to accept the command. The start_cmd bit changes to 0 when the command is accepted.†

   The following actions occur when the command is loaded into the controller:†

   - If no previous command is being processed, the controller accepts the command for execution and resets the start_cmd bit in the cmd register to 0. If a previous command is being processed, the controller loads the new command in the command buffer.†
   - If the controller is unable to load the new command—that is, a command is already in progress, a second command is in the buffer, and a third command is attempted—the controller generates a hardware lock error.†
4. Check if there is a hardware lock error.†
5. Wait for command execution to complete. After receiving either a response from a card or response timeout, the controller sets the command_done bit in the rintsts register to 1. Software can either poll for this bit or respond to a generated interrupt (if enabled).†
6. Check if the response timeout boot acknowledge received (bar), rcrc, or re bit is set to 1. Software can either respond to an interrupt raised by these errors or poll the re, rcrc, and bar bits of the rintsts register. If no response error is received, the response is valid. If required, software can copy the response from the response registers.†

Note: Software cannot modify clock parameters while a command is being executed.†

Related Information

cmd Register Settings for Non-Data Transfer Command† on page 14-45
Refer to this table for information about Non-Data Transfer commands.

cmd Register Settings for Non-Data Transfer Command†

Table 14-20: Default

Parameter	Value	Comment
start_cmd	1	This bit resets itself to 0 after the command is committed.
use_hold_reg	1 or 0	Choose the value based on the speed mode used.
update_clk_regs_only	0	Indicates that the command is not a clock update command
data_expected	0	Indicates that the command is not a data command
card_number	1	For one card

Parameter	Value	Comment
cmd_index	Command Index	Set this parameter to the command number. For example, set to 8 for the SD/SDIO SEND_IF_COND (CMD8) command.
send_initialization	0 or 1	1 for card reset commands such as the SD/SDIO GO_IDLE_STATE command 0 otherwise
stop_abort_cmd	0 or 1	1 for a command to stop data transfer, such as the SD/SDIO STOP_TRANSMISSION command 0 otherwise
response_length	0 or 1	1 for R2 (long) response 0 for short response
response_expect	0 or 1	0 for commands with no response, such as SD/SDIO GO_IDLE_STATE, SET_DSR (CMD4), or GO_INACTIVE_STATE (CMD15). 1 otherwise

Table 14-21: User Selectable

Parameter	Value	Comment
wait_prvdata_complete	1	Before sending a command on the command line, the host must wait for completion of any data command already in process. Altera recommends that you set this bit to 1, unless the current command is to query status or stop data transfer when transfer is in progress.
check_response_crc	1 or 0	1 if the response includes a valid CRC, and the software is required to crosscheck the response CRC bits. 0 otherwise

Data Transfer Commands

Data transfer commands transfer data between the memory card and the controller. To issue a data command, the controller requires a command argument, total data size, and block size. Data transferred to or from the memory card is buffered by the controller FIFO buffer.†

Confirming Transfer State

Before issuing a data transfer command, software must confirm that the card is not busy and is in a transfer state, by performing the following steps:†

1. Issue an SD/SDIO SEND_STATUS (CMD13) command. The controller sends the status of the card as the response to the command.†
2. Check the card's busy status.†
3. Wait until the card is not busy.†
4. Check the card's transfer status. If the card is in the stand-by state, issue an SD/SDIO SELECT/DESELECT_CARD (CMD7) command to place it in the transfer state.†

Busy Signal After CE-ATA RW_BLK Write Transfer

During CE-ATA RW_BLK write transfers, the MMC busy signal might be asserted after the last block. If the CE-ATA card device interrupt is disabled (the nIEN bit in the card device's ATA control register is set to 1), the `dto` bit in the `rintsts` register is set to 1 even though the card sends MMC BUSY. The host cannot issue the CMD60 command to check the ATA busy status after a CMD61 command. Instead, the host must perform one of the following actions:†

- Issue the SEND_STATUS command and check the MMC busy status before issuing a new CMD60 command†
- Issue the CMD39 command and check the ATA busy status before issuing a new CMD60 command†

For the data transfer commands, software must set the `ctype` register to the bus width that is programmed in the card.†

Data Transfer Interrupts

The controller generates an interrupt for different conditions during data transfer, which are reflected in the following `rintsts` register bits:†

1. `dto`—Data transfer is over or terminated. If there is a response timeout error, the controller does not attempt any data transfer and the Data Transfer Over bit is never set.†
2. Transmit FIFO data request bit (`txdr`)—The FIFO buffer threshold for transmitting data is reached; software is expected to write data, if available, into the FIFO buffer.†
3. Receive FIFO data request bit (`rxdr`)—The FIFO buffer threshold for receiving data is reached; software is expected to read data from the FIFO buffer.†
4. `hto`—The FIFO buffer is empty during transmission or is full during reception. Unless software corrects this condition by writing data for empty condition, or reading data for full condition, the controller cannot continue with data transfer. The clock to the card is stopped.†
5. `bds`—The card has not sent data within the timeout period.†
6. `dcrc`—A CRC error occurred during data reception.†
7. `sbe`—The start bit is not received during data reception.†
8. `ebe`—The end bit is not received during data reception, or for a write operation. A CRC error is indicated by the card.†

`dcrc`, `sbe`, and `ebe` indicate that the received data might have errors. If there is a response timeout, no data transfer occurs.†

Single-Block or Multiple-Block Read

To implement a single-block or multiple-block read, the software performs the following steps:†

1. Write the data size in bytes to the `bytcnt` register. For a multi-block read, `bytcnt` must be a multiple of the block size.†
2. Write the block size in bytes to the `blksiz` register. The controller expects data to return from the card in blocks of size `blksiz`.†
3. If the read round trip delay, including the card delay, is greater than half of `sdmmc_clk_divided`, write to the card threshold control register (`cardthrctl`) to ensure that the card clock does not stop in the

middle of a block of data being transferred from the card to the host. For more information, refer to *Card Read Threshold*.†

Note: If the card read threshold enable bit (`cardrdthren`) is 0, the host system must ensure that the RX FIFO buffer does not become full during a read data transfer by ensuring that the RX FIFO buffer is read at a rate faster than that at which data is written into the FIFO buffer. Otherwise, an overflow might occur.†

4. Write the `cmdarg` register with the beginning data address for the data read.†
5. Write the `cmd` register with the parameters listed in *cmd Register Settings for Single-Block and Multiple-Block Reads*. For SD and MMC cards, use the SD/SDIO READ_SINGLE_BLOCK (CMD17) command for a single-block read and the READ_MULTIPLE_BLOCK (CMD18) command for a multiple-block read. For SDIO cards, use the IO_RW_EXTENDED (CMD53) command for both single-block and multiple-block transfers. The command argument for (CMD53) is shown in the figure, below. After writing to the `cmd` register, the controller starts executing the command. When the command is sent to the bus, the Command Done interrupt is generated.†
6. Software must check for data error interrupts, reported in the `dcrc`, `bds`, `sbe`, and `ebe` bits of the `rintsts` register. If required, software can terminate the data transfer by sending an SD/SDIO STOP command.†
7. Software must check for host timeout conditions in the `rintsts` register:†
   - Receive FIFO buffer data request†
   - Data starvation from host—the host is not reading from the FIFO buffer fast enough to keep up with data from the card. To correct this condition, software must perform the following steps:†
     - Read the `fifo_count` field of the `status` register†
     - Read the corresponding amount of data out of the FIFO buffer†

   In both cases, the software must read data from the FIFO buffer and make space in the FIFO buffer for receiving more data.†
8. When a DTO interrupt is received, the software must read the remaining data from the FIFO buffer.†

cmd Register Settings for Single-Block and Multiple-Block Reads†

Table 14-22: cmd Register Settings for Single-Block and Multiple-Block Reads (Default)

Parameter	Value	Comment
start_cmd	1	This bit resets itself to 0 after the command is committed.
use_hold_reg	1 or 0	Choose the value based on speed mode used.
update_clk_regs_only	0	Does not need to update clock parameters
data_expected	1	Data command
card_number	1	For one card
transfer_mode	0	Block transfer

Parameter	Value	Comment
send_initialization	0	1 for a card reset command such as the SD/SDIO GO_IDLE_STATE command 0 otherwise
stop_abort_cmd	0	1 for a command to stop data transfer such as the SD/SDIO STOP_TRANSMISSION command 0 otherwise
send_auto_stop	0 or 1	Refer to *Auto Stop* for information about how to set this parameter.
read_write	0	Read from card
response_length	0	1 for R2 (long) response 0 for short response
response_expect	1 or 0	0 for commands with no response, such as SD/SDIO GO_IDLE_STATE, SET_DSR, and GO_INACTIVE_STATE. 1 otherwise

Table 14-23: cmd Register Settings for Single-Block and Multiple-Block Reads (User Selectable)

Parameter	Value	Comment
wait_prvdata_complete	1 or 0	0 - sends command to CIU immediately 1 - sends command after previous data transfer ends
check_response_crc	1 or 0	0 - Controller must not check response CRC 1 - Controller must check responce CRC
cmd_index	Command Index	Set this parameter to the command number. For example, set to 17 or 18 for SD/SDIO READ_SINGLE_BLOCK (CMS17) or READ_MULTIPLE_BLOCK (CMD18)

Related Information

Auto-Stop on page 14-28
Refer to this table for information about setting the send_auto_stop parameter.

Single-Block or Multiple-Block Write

The following steps comprise a single-block or multiple-block write:

1. Write the data size in bytes to the `bytcnt` register. For a multi-block write, `bytcnt` must be a multiple of the block size.†
2. Write the block size in bytes to the `blksiz` register. The controller sends data in blocks of size `blksiz` each.†
3. Write the `cmdarg` register with the data address to which data must be written.†
4. Write data into the FIFO buffer. For best performance, the host software should write data continuously until the FIFO buffer is full.†
5. Write the `cmd` register with the parameters listed in *cmd Register Settings for Single-Block and Multiple-Block Write*. For SD and MMC cards, use the SD/SDIO WRITE_BLOCK (CMD24) command for a single-block write and the WRITE_MULTIPLE_BLOCK (CMD25) command for a multiple-block writes. For SDIO cards, use the IO_RW_EXTENDED command for both single-block and multiple-block transfers.†

   After writing to the `cmd` register, the controller starts executing a command if there is no other command already being processed. When the command is sent to the bus, a Command Done interrupt is generated.†
6. Software must check for data error interrupts; that is, for `dcrc`, `bds`, and `ebe` bits of the `rintsts` register. If required, software can terminate the data transfer early by sending the SD/SDIO STOP command.†
7. Software must check for host timeout conditions in the `rintsts` register: †

   - Transmit FIFO buffer data request.†
   - Data starvation by the host—the controller wrote data to the card faster than the host could supply the data.†

   In both cases, the software must write data into the FIFO buffer.†

   There are two types of transfers: open-ended and fixed length.†

   - Open-ended transfers—For an open-ended block transfer, the byte count is 0. At the end of the data transfer, software must send the STOP_TRANSMISSION command (CMD12).†
   - Fixed-length transfers—The byte count is nonzero. You must already have written the number of bytes to the `bytcnt` register. The controller issues the STOP command for you if you set the `send_auto_stop` bit of the `cmd` register to 1. After completion of a transfer of a given number of bytes, the controller sends the STOP command. Completion of the AUTO_STOP command is reflected by the Auto Command Done interrupt. A response to the AUTO_STOP command is written to the `resp1` register. If software does not set the `send_auto_stop` bit in the `cmd` register to 1, software must issue the STOP command just like in the open-ended case.†

When the `dto` bit of the `rintsts` register is set, the data command is complete.†

cmd Register Settings for Single-Block and Multiple-Block Write

Table 14-24: cmd Register Settings for Single-Block and Multiple-Block Write (Default)†

Parameter	Value	Comment
`start_cmd`	1	This bit resets itself to 0 after the command is committed (accepted by the BIU).
`use_hold_reg`	1 or 0	Choose the value based on speed mode used.
`update_clk_regs_only`	0	Does not need to update clock parameters

Parameter	Value	Comment
data_expected	1	Data command
card_number	1	For one card
transfer_mode	0	Block transfer
send_initialization	0	Can be 1, but only for card reset commands such as SD/SDIO GO_IDLE_STATE
stop_abort_cmd	0	Can be 1 for commands to stop data transfer such as SD/SDIO STOP_TRANSMISSION
send_auto_stop	0 or 1	Refer to *Auto Stop* for information about how to set this parameter.
read_write	1	Write to card
response_length	0	Can be 1 for R2 (long) responses
response_expect	1	Can be 0 for commands with no response. For example, SD/SDIO GO_IDLE_STATE, SET_DSR, GO_INACTIVE_STATE etc.

Table 14-25: cmd Register Settings for Single-Block and Multiple-Block Write (User Selectable)†

Parameter	Value	Comment
wait_prvdata_complete	1	0—Sends command to the CIU immediately 1—Sends command after previous data transfer ends
check_response_crc	1	0—Controller must not check response CRC 1—Controller must check response CRC
cmd_index	Command Index	Set this parameter to the command number. For example, set to 24 for SD/SDIO WRITE_BLOCK (CMD24) or 25 for WRITE_MULTIPLE_BLOCK (CMD25).

Related Information

Auto-Stop on page 14-28
Refer to this table for information about setting the send_auto_stop parameter.

Stream Read and Write

In a stream transfer, if the byte count is equal to 0, the software must also send the SD/SDIO STOP command. If the byte count is not 0, when a given number of bytes completes a transfer, the controller sends the STOP command automatically. Completion of this AUTO_STOP command is reflected by the

Auto_command_done interrupt. A response to an AUTO_STOP command is written to the `resp1` register. A stream transfer is allowed only for card interfaces with a 1-bit data bus.†

A stream read requires the same steps as the block read described in *Single-Block or Multiple-Block Read*, except for the following bits in the `cmd` register:†

- `transfer_mode` = 0x1 (for stream transfer)†
- `cmd_index` = 20 (SD/SDIO CMD20)†

A stream write requires the same steps as the block write mentioned in *Single-Block or Multiple-Block Write*, except for the following bits in the `cmd` register:†

- `transfer_mode` = 0x1 (for stream transfer)†
- `cmd_index` = 11 (SD/SDIO CMD11)†

Related Information

- **Single-Block or Multiple-Block Read** on page 14-47
  Refer to this section for more information about a stream read.
- **Single-Block or Multiple-Block Write** on page 14-50
  Refer to this section for more information about a stream write.

Packed Commands

To reduce overhead, read and write commands can be packed in groups of commands—either all read or all write—that transfer the data for all commands in the group in one transfer on the bus. Use the SD/SDIO SET_BLOCK_COUNT (CMD23) command to state ahead of time how many blocks will be transferred. Then issue a single READ_MULTIPLE_BLOCK or WRITE_MULTIPLE_BLOCK command to read or write multiple blocks.†

- SET_BLOCK_COUNT—set block count (number of blocks transferred using the READ_MULTIPLE_BLOCK or WRITE_MULTIPLE_BLOCK command) †
- READ_MULTIPLE_BLOCK—multiple-block read command †
- WRITE_MULTIPLE_BLOCK—multiple-block write command†

Packed commands are organized in packets by the application software and are transparent to the controller.†

Related Information

www.jedec.org
For more information about packed commands, refer to JEDEC Standard No. 84-A441, available on the JEDEC website.

Transfer Stop and Abort Commands

This section describes stop and abort commands. The SD/SDIO STOP_TRANSMISSION command can terminate a data transfer between a memory card and the controller. The ABORT command can terminate an I/O data transfer for only an SDIO card. †

STOP_TRANSMISSION (CMD12)

The host can send the STOP_TRANSMISSION (CMD12) command on the CMD pin at any time while a data transfer is in progress. Perform the following steps to send the STOP_TRANSMISSION command to the SD/SDIO card device:†

1. Set the `wait_prvdata_complete` bit of the `cmd` register to 0.†
2. Set the `stop_abort_cmd` in the `cmd` register to 1, which ensures that the CIU stops.†

The STOP_TRANSMISSION command is a non-data transfer command.†

Related Information

Non-Data Transfer Commands on page 14-44
Refer to this section for information on the STOP_TRANSMISSION command.

ABORT

The ABORT command can only be used with SDIO cards. To abort the function that is transferring data, program the ABORT function number in the ASx[2:0] bits at address 0x06 of the card common control register (CCCR) in the card device, using the IO_RW_DIRECT (CMD52) command. The CCCR is located at the base of the card space 0x00 – 0xFF.†

Note: The ABORT command is a non-data transfer command.†

Related Information

Non-Data Transfer Commands on page 14-44
Refer to this section for information on the ABORT command.

Sending the ABORT Command

Perform the following steps to send the ABORT command to the SDIO card device:†

1. Set the `cmdarg` register to include the appropriate command argument parameters listed in *cmdarg Register Settings for SD/SDIO ABORT Command*.†
2. Send the IO_RW_DIRECT command by setting the following fields of the `cmd` register:†
   - Set the command index to 0x52 (IO_RW_DIRECT).†
   - Set the `stop_abort_cmd` bit of the `cmd` register to 1 to inform the controller that the host aborted the data transfer.†
   - Set the `wait_prvdata_complete` bit of the `cmd` register to 0.†
3. Wait for the `cmd` bit in the `rintsts` register to change to 1.†
4. Read the response to the IO_RW_DIRECT command (R5) in the response registers for any errors.†

For more information about response values, refer to the Physical Layer Simplified Specification, Version 3.01, available on the SD Association website.

Related Information

www.sdcard.org
To learn more about how SD technology works, visit the SD Association website.

cmdarg Register Settings for SD/SDIO ABORT Command†

Table 14-26: cmdarg Register Settings for SD/SDIO ABORT Command

Bits	Contents	Value
31	R/W flag	1
30:28	Function number	0, for access to the CCCR in the card device

Bits	Contents	Value
27	RAW flag	1, if needed to read after write
26	Don't care	-
25:9	Register address	0x06
8	Don't care	-
7:0	Write data	Function number to abort

Internal DMA Controller Operations

For better performance, you can use the internal DMA controller to transfer data between the host and the controller. This section describes the internal DMA controller's initialization process, and transmission sequence, and reception sequence.

Internal DMA Controller Initialization

To initialize the internal DMA controller, perform the following steps:†

1. Set the required `bmod` register bits: †
   - If the internal DMA controller enable bit (`de`) of the `bmod` register is set to 0 during the middle of a DMA transfer, the change has no effect. Disabling only takes effect for a new data transfer command.†
   - Issuing a software reset immediately terminates the transfer. Prior to issuing a software reset, Altera recommends the host reset the DMA interface by setting the `dma_reset` bit of the `ctrl` register to 1.†
   - The `pbl` field of the `bmod` register is read-only and a direct reflection of the contents of the DMA multiple transaction size field (`dw_dma_multiple_transaction_size`) in the `fifoth` register.†
   - The `fb` bit of the `bmod` register has to be set appropriately for system performance.†
2. Write to the `idinten` register to mask unnecessary interrupt causes according to the following guidelines:†
   - When a Descriptor Unavailable interrupt is asserted, the software needs to form the descriptor, appropriately set its own bit, and then write to the poll demand register (`pldmnd`) for the internal DMA controller to re-fetch the descriptor.†
   - It is always appropriate for the software to enable abnormal interrupts because any errors related to the transfer are reported to the software.†
3. Populate either a transmit or receive descriptor list in memory. Then write the base address of the first descriptor in the list to the internal DMA controller's descriptor list base address register (`dbaddr`). The DMA controller then proceeds to load the descriptor list from memory. *Internal DMA Controller Transmission Sequences* and *Internal DMA Controller Reception Sequences* describe this step in detail. †

Related Information

- **Internal DMA Controller Transmission Sequences** on page 14-56
  Refer to this section for information about the Internal DMA Controller Transmission Sequences.
- **Internal DMA Controller Reception Sequences** on page 14-56
  Refer to this section for information about the Internal DMA Controller Reception Sequences.

Internal DMA Controller Transmission Sequences

To use the internal DMA controller to transmit data, perform the following steps:

1. The host sets up the Descriptor fields (DES0—DES3) for transmission and sets the OWN bit (DES0[31]) to 1. The host also loads the data buffer in system memory with the data to be written to the SD card.†
2. The host writes the appropriate write data command (SD/SDIO WRITE_BLOCK or WRITE_MULTIPLE_BLOCK) to the `cmd` register. The internal DMA controller determines that a write data transfer needs to be performed.†
3. The host sets the required transmit threshold level in the `tx_wmark` field in the `fifoth` register.†
4. The internal DMA controller engine fetches the descriptor and checks the OWN bit. If the OWN bit is set to 0, the host owns the descriptor. In this case, the internal DMA controller enters the suspend state and asserts the Descriptor Unable interrupt. The host then needs to set the descriptor OWN bit to 1 and release the DMA controller by writing any value to the `pldmnd` register.†
5. The host must write the descriptor base address to the `dbaddr` register.†
6. The internal DMA controller waits for the Command Done (`CD`) bit in the `rintsts` register to be set to 1, with no errors from the BIU. This condition indicates that a transfer can be done.†
7. The internal DMA controller engine waits for a DMA interface request from BIU. The BIU divides each transfer into smaller chunks. Each chunk is an internal request to the DMA. This request is generated based on the transmit threshold value.†
8. The internal DMA controller fetches the transmit data from the data buffer in the system memory and transfers the data to the FIFO buffer in preparation for transmission to the card.†
9. When data spans across multiple descriptors, the internal DMA controller fetches the next descriptor and continues with its operation with the next descriptor. The Last Descriptor bit in the descriptor DES0 field indicates whether the data spans multiple descriptors or not.†
10. When data transmission is complete, status information is updated in the `idsts` register by setting the `ti` bit to 1, if enabled. Also, the OWN bit is set to 0 by the DMA controller by updating the DES0 field of the descriptor.†

Internal DMA Controller Reception Sequences

To use the internal DMA controller to receive data, perform the following steps:

1. The host sets up the descriptor fields (DES0—DES3) for reception, sets the OWN (DES0 [31]) to 1.†
2. The host writes the read data command to the `cmd` register in BIU. The internal DMA controller determines that a read data transfer needs to be performed.†
3. The host sets the required receive threshold level in the `rx_wmark` field in the `fifoth` register.†
4. The internal DMA controller engine fetches the descriptor and checks the OWN bit. If the OWN bit is set to 0, the host owns the descriptor. In this case, the internal DMA controller enters suspend state and asserts the Descriptor Unable interrupt. The host then needs to set the descriptor OWN bit to 1 and release the DMA controller by writing any value to the `pldmnd` register.†
5. The host must write the descriptor base address to the `dbaddr` register.†
6. The internal DMA controller waits for the `CD` bit in the `rintsts` register to be set to 1, with no errors from the BIU. This condition indicates that a transfer can be done.†
7. The internal DMA controller engine waits for a DMA interface request from the BIU. The BIU divides each transfer into smaller chunks. Each chunk is an internal request to the DMA. This request is generated based on the receive threshold value.†

8. The internal DMA controller fetches the data from the FIFO buffer and transfers the data to system memory.†
9. When data spans across multiple descriptors, the internal DMA controller fetches the next descriptor and continues with its operation with the next descriptor. The Last Descriptor bit in the descriptor indicates whether the data spans multiple descriptors or not.†
10. When data reception is complete, status information is updated in the `idsts` register by setting the `ri` bit to 1, if enabled. Also, the OWN bit is set to 0 by the DMA controller by updating the DES0 field of the descriptor.†

Commands for SDIO Card Devices

This section describes the commands to temporarily halt the transfers between the controller and SDIO card device.

Suspend and Resume Sequence

For SDIO cards, a data transfer between an I/O function and the controller can be temporarily halted using the SUSPEND command. This capability might be required to perform a high-priority data transfer with another function. When desired, the suspended data transfer can be resumed using the RESUME command.†

The SUSPEND and RESUME operations are implemented by writing to the appropriate bits in the CCCR (Function 0) of the SDIO card. To read from or write to the CCCR, use the controller's IO_RW_DIRECT command.†

Suspend

To suspend data transfer, perform the following steps:†

1. Check if the SDIO card supports the SUSPEND/RESUME protocol. This can be done through the SBS bit in the CCCR at offset 0x08 of the card.†
2. Check if the data transfer for the required function number is in process. The function number that is currently active is reflected in the function select bits (FSx) of the CCCR, bits 3:0 at offset 0x0D of the card.†

   Note: If the bus status bit (BS), bit 0 at address 0xC, is 1, only the function number given by the FSx bits is valid.†
3. To suspend the transfer, set the bus release bit (BR), bit 2 at address 0xC, to 1.†
4. Poll the BR and BS bits of the CCCR at offset 0x0C of the card until they are set to 0. The BS bit is 1 when the currently-selected function is using the data bus. The BR bit remains 1 until the bus release is complete. When the BR and BS bits are 0, the data transfer from the selected function is suspended.†
5. During a read-data transfer, the controller can be waiting for the data from the card. If the data transfer is a read from a card, the controller must be informed after the successful completion of the SUSPEND command. The controller then resets the data state machine and comes out of the wait state. To accomplish this, set the abort read data bit (`abort_read_data`) in the `ctrl` register to 1.†
6. Wait for data completion, by polling until the `dto` bit is set to 1 in the `rintsts` register. To determine the number of pending bytes to transfer, read the transferred CIU card byte count (`tcbcnt`) register of the controller. Subtract this value from the total transfer size. You use this number to resume the transfer properly.†

Resume

To resume the data transfer, perform the following steps:†

1. Check that the card is not in a transfer state, which confirms that the bus is free for data transfer.†
2. If the card is in a disconnect state, select it using the SD/SDIO SELECT/DESELECT_CARD command. The card status can be retrieved in response to an IO_RW_DIRECT or IO_RW_EXTENDED command.†
3. Check that a function to be resumed is ready for data transfer. Determine this state by reading the corresponding RF<*n*> flag in CCCR at offset 0x0F of the card. If RF<*n*> = 1, the function is ready for data transfer.†

   Note: For detailed information about the RF<*n*> flags, refer to SDIO Simplified Specification Version 2.00, available on the SD Association website.†
4. To resume transfer, use the IO_RW_DIRECT command to write the function number at the FSx bits in the CCCR, bits 3:0 at offset 0x0D of the card. Form the command argument for the IO_RW_DIRECT command and write it to the `cmdarg` register. Bit values are listed in the following table.†

Table 14-27: cmdarg Bit Values for RESUME Command†

Bits	Content	Value
31	R/W flag	1
30:28	Function number	0, for CCCR access
27	RAW flag	1, read after write
26	Don't care	-
25:9	Register address	0x0D
8	Don't care	-
7:0	Write data	Function number that is to be resumed

5. Write the block size value to the `blksiz` register. Data is transferred in units of this block size.†
6. Write the byte count value to the `bytcnt` register. Specify the total size of the data that is the remaining bytes to be transferred. It is the responsibility of the software to handle the data.†

   To determine the number of pending bytes to transfer, read the transferred CIU card byte count register (`tcbcnt`). Subtract this value from the total transfer size to calculate the number of remaining bytes to transfer.†
7. Write to the `cmd` register similar to a block transfer operation. When the `cmd` register is written, the command is sent and the function resumes data transfer. For more information, refer to *Single-Block or Multiple-Block Read* and *Single-Block or Multiple-Block Write*.†
8. Read the resume data flag (DF) of the SDIO card device. Interpret the DF flag as follows:†

- DF=1—The function has data for the transfer and begins a data transfer as soon as the function or memory is resumed.†
- DF=0—The function has no data for the transfer. If the data transfer is a read, the controller waits for data. After the data timeout period, it issues a data timeout error.†

Read-Wait Sequence

Read_wait is used with SDIO cards only. It temporarily stalls the data transfer, either from functions or memory, and allows the host to send commands to any function within the SDIO card device. The host can stall this transfer for as long as required. The controller provides the facility to signal this stall transfer to the card.†

Signalling a Stall

To signal the stall, perform the following steps:†

1. Check if the card supports the read_wait facility by reading the SDIO card's SRW bit, bit 2 at offset 0x8 in the CCCR.†
2. If this bit is 1, all functions in the card support the read_wait facility. Use the SD/SDIO IO_RW_DIRECT command to read this bit.†
3. If the card supports the `read_wait` signal, assert it by setting the read wait bit (`read_wait`) in the `ctrl` register to 1.†
4. Reset the `read_wait` bit to 0 in the `ctrl` register.†

CE-ATA Data Transfer Commands

This section describes CE-ATA data transfer commands.

Related Information

Data Transfer Commands on page 14-46
Refer to this section for information about the basic settings and interrupts generated for different conditions.

Reset and Card Device Discovery Overview

Before starting any CE-ATA operations, the host must perform a MMC reset and initialization procedure. The host and card device must negotiate the MMC transfer (MMC TRAN) state before the card enters the MMC TRAN state.†

The host must follow the existing MMC discovery procedure to negotiate the MMC TRAN state. After completing normal MMC reset and initialization procedures, the host must query the initial ATA task file values using the RW_REG or CMD39 command.†

By default, the MMC block size is 512 bytes—indicated by bits 1:0 of the srcControl register inside the CE-ATA card device. The host can negotiate the use of a 1 KB or 4 KB MMC block sizes. The card indicates MMC block sizes that it can support through the srcCapabilities register in the MMC; the host

reads this register to negotiate the MMC block size. Negotiation is complete when the host controller writes the MMC block size into the srcControl register bits 1:0 of the card.†

Related Information

www.jedec.org
For information about the (MMC TRAN) state, MMC reset and initialization, refer to JEDEC Standard No. 84-A441, available on the JEDEC website.

ATA Task File Transfer Overview

ATA task file registers are mapped to addresses 0x00h through 0x10h in the MMC register space. The RW_REG command is used to issue the ATA command, and the ATA task file is transmitted in a single RW_REG MMC command sequence.†

The host software stack must write the task file image to the FIFO buffer before setting the `cmdarg` and `cmd` registers in the controller. The host processor then writes the address and byte count to the `cmdarg` register before setting the `cmd` register bits.†

For the RW_REG command, there is no CCS from the CE-ATA card device. †

ATA Task File Transfer Using the RW_MULTIPLE_REGISTER (RW_REG) Command

This command involves data transfer between the CE-ATA card device and the controller. To send a data command, the controller needs a command argument, total data size, and block size. Software receives or sends data through the FIFO buffer.†

Implementing ATA Task File Transfer

To implement an ATA task file transfer (read or write), perform the following steps:†

1. Write the data size in bytes to the `bytcnt` register. `bytcnt` must equal the block size, because the controller expects a single block transfer.†
2. Write the block size in bytes to the `blksiz` register.†
3. Write the `cmdarg` register with the beginning register address.†

You must set the `cmdarg`, `cmd`, `blksiz`, and `bytcnt` registers according to the tables in *Register Settings for ATA Task File Transfer*.†

Related Information

Register Settings for ATA Task File Transfer on page 14-60
Refer to this table for information on how to set these registers.

Register Settings for ATA Task File Transfer

Table 14-28: cmdarg Register Settings for ATA Task File Transfer†

Bit	Value	Comment
31	1 or 0	Set to 0 for read operation or set to 1 for write operation
30:24	0	Reserved (bits set to 0 by host processor)
23:18	0	Starting register address for read or write (DWORD aligned)

Bit	Value	Comment
17:16	0	Register address (DWORD aligned)
15:8	0	Reserved (bits set to 0 by host processor)
7:2	16	Number of bytes to read or write (integral number of DWORD)
1:0	0	Byte count in integral number of DWORD

Table 14-29: cmd Register Settings for ATA Task File Transfer†

Bit	Value	Comment
`start_cmd`	1	
`ccs_expected`	0	CCS is not expected
`read_ceata_device`	0 or 1	Set to 1 if RW_BLK or RW_REG read
`update_clk_regs_only`	0	No clock parameters update command
`card_num`	0	
`send_initialization`	0	No initialization sequence
`stop_abort_cmd`	0	
`send_auto_stop`	0	
`transfer_mode`	0	Block transfer mode. Block size and byte count must match number of bytes to read or write
`read_write`	1 or 0	1 for write and 0 for read
`data_expected`	1	Data is expected
`response_length`	0	
`response_expect`	1	
`cmd_index`	Command index	Set this parameter to the command number. For example, set to 24 for SD/SDIO WRITE_BLOCK (CMD24) or 25 for WRITE_MULTIPLE_BLOCK (CMD25).
`wait_prvdata_complete`	1	• 0 for send command immediately • 1 for send command after previous DTO interrupt

Bit	Value	Comment
check_response_crc	1	• 0 for not checking response CRC • 1 for checking response CRC

Table 14-30: blksiz Register Settings for ATA Task File Transfer†

Bit	Value	Comment
31:16	0	Reserved bits set to 0
15:0 (block_size)	16	For accessing entire task file (16, 8-bit registers). Block size of 16 bytes

Table 14-31: bytcnt Register Settings for ATA Task File Transfer

Bit	Value	Comment
31:0	16	For accessing entire task file (16, 8-bit registers). Byte count value of 16 is used with the block size set to 16.

ATA Payload Transfer Using the RW_MULTIPLE_BLOCK (RW_BLK) Command

This command involves data transfer between the CE-ATA card device and the controller. To send a data command, the controller needs a command argument, total data size, and block size. Software receives or sends data through the FIFO buffer. †

Implementing ATA Payload Transfer

To implement an ATA payload transfer (read or write), perform the following steps:†

1. Write the data size in bytes to the bytcnt register.†
2. Write the block size in bytes to the blksiz register. The controller expects a single/multiple block transfer.†
3. Write to the cmdarg register to indicate the data unit count.†

Register Settings for ATA Payload Transfer

You must set the cmdarg, cmd, blksiz, and bytcnt registers according to the following tables.†

Table 14-32: cmdarg Register Settings for ATA Payload Transfer†

Bits	Value	Comment
31	1 or 0	Set to 0 for read operation or set to 1 for write operation
30:24	0	Reserved (bits set to 0 by host processor)
23:16	0	Reserved (bits set to 0 by host processor)
15:8	Data count	Data Count Unit [15:8]

Bits	Value	Comment
7:0	Data count	Data Count Unit [7:0]

Table 14-33: cmd Register Settings for ATA Payload Transfer†

Bits	Value	Comment
start_cmd	1	-
ccs_expected	1	CCS is expected. Set to 1 for the RW_BLK command if interrupts are enabled in CE-ATA card device (the nIEN bit is set to 0 in the ATA control register)
read_ceata_device	0 or 1	Set to 1 for a RW_BLK or RW_REG read command
update_clk_regs_only	0	No clock parameters update command
card_num	0	-
send_initialization	0	No initialization sequence
stop_abort_cmd	0	-
send_auto_stop	0	-
transfer_mode	0	Block transfer mode. Byte count must be integer multiple of 4kB. Block size can be 512, 1k or 4k bytes
read_write	1 or 0	1 for write and 0 for read
data_expected	1	Data is expected
response_length	0	-
response_expect	1	-
cmd_index	Command index	Set this parameter to the command number. For example, set to 24 for SD/SDIO WRITE_BLOCK (CMD24) or 25 for WRITE_MULTIPLE_BLOCK (CMD25).
wait_prvdata_complete	1	• 0 for send command immediately • 1 for send command after previous DTO interrupt

Bits	Value	Comment
check_response_crc	1	• 0 for not checking response CRC • 1 for checking response CRC

Table 14-34: blksiz Register Settings for ATA Payload Transfer†

Bits	Value	Comment
31:16	0	Reserved bits set to 0
15:0 (block_size)	512, 1024 or 4096	MMC block size can be 512, 1024 or 4096 bytes as negotiated by host

Table 14-35: bytcnt Register Settings for ATA Payload Transfer

Bits	Value	Comment
31:0	<n>*block_size	Byte count must be an integer multiple of the block size. For ATA media access commands, byte count must be a multiple of 4 KB. (<*n*>*block_size = <*x*>*4 KB, where <*n*> and <*x*> are integers)

CE-ATA CCS

This section describes disabling the CCS, recovery after CCS timeout, and recovery after I/O read transmission delay (N_{ACIO}) timeout. †

Disabling the CCS

While waiting for the CCS for an outstanding RW_BLK command, the host can disable the CCS by sending a CCSD command:†

- Send a CCSD command—the controller sends the CCSD command to the CE-ATA card device if the send_ccsd bit is set to 1 in the ctrl register of the controller. This bit can be set only after a response is received for the RW_BLK command.†
- Send an internal stop command—send an internally-generated SD/SDIO STOP_TRANSMISSION (CMD12) command after sending the CCSD pattern. If the send_auto_stop_ccsd bit of the ctrl register is also set to 1 when the controller is set to send the CCSD pattern, the controller sends the internally-generated STOP command to the CMD pin. After sending the STOP command, the controller sets the acd bit in the rintsts register to 1.†

Recovery after CCS Timeout

If a timeout occurs while waiting for the CCS, the host needs to send the CCSD command followed by a STOP command to abort the pending ATA command. The host can set up the controller to send an internally-generated STOP command after sending the CCSD pattern:†

- Send CCSD command—set the `send_ccsd` bit in the `ctrl` register to 1.†
- Send external STOP command—terminate the data transfer between the CE-ATA card device and the controller. For more information about sending the STOP command, refer to *Transfer Stop and Abort Commands*.†
- Send internal STOP command—set the `send_auto_stop_ccsd` bit in the `ctrl` register to 1, which tells the controller to send the internally-generated STOP command. After sending the STOP command, the controller sets the `acd` bit in the `rintsts` register to 1. The `send_auto_stop_ccsd` bit must be set to 1 along with setting the `send_ccsd` bit.†

Related Information

Transfer Stop and Abort Commands on page 14-53
Refer to this section for more information about sending the STOP command.

Recovery after I/O Read Transmission Delay (N_{ACIO}) Timeout

If the I/O read transmission delay (N_{ACIO}) timeout occurs for the CE-ATA card device, perform one of the following steps to recover from the timeout:†

- If the CCS is expected from the CE-ATA card device (that is, the `ccs_expected` bit is set to 1 in the `cmd` register), follow the steps in *Recovery after CCS Timeout*.†
- If the CCS is not expected from the CE-ATA card device, perform the following steps: †

1. Send an external STOP command. †
2. Terminate the data transfer between the controller and CE-ATA card device. †

Related Information

Recovery after CCS Timeout on page 14-64
For more information about what steps to take if the CCS is expected from the CE-ATA card device.

Reduced ATA Command Set

It is necessary for the CE-ATA card device to support the reduced ATA command subset. This section describes the reduced command set.†

The IDENTIFY DEVICE Command

The IDENTIFY DEVICE command returns a 512-byte data structure to the host that describes device-specific information and capabilities. The host issues the IDENTIFY DEVICE command only if the MMC block size is set to 512 bytes. Any other MMC block size has indeterminate results.†

The host issues a RW_REG command for the ATA command, and the data is retrieved with the RW_BLK command.†

The host controller uses the following settings while sending a RW_REG command for the IDENTIFY DEVICE ATA command. The following list shows the primary bit settings:†

- `cmd` register setting: `data_expected` bit set to 0†
- `cmdarg` register settings: †
  - Bit [31] set to 0†
  - Bits [7:2] set to 128 †
  - All other bits set to 0†
- Task file settings: †
  - Command field of the ATA task file set to 0xEC†
  - Reserved fields of the task file set to 0†
- `bytcnt` register and `block_size` field of the `blksiz` register: set to 16†

The host controller uses the following settings for data retrieval (RW_BLK command):†

- `cmd` register settings:†
  - `ccs_expected` set to 1†
  - `data_expected` set to 1†
- `cmdarg` register settings: †
  - Bit [31] set to 0 (read operation) †
  - Bits [15:0] set to 1 (data unit count = 1)†
  - All other bits set to 0†
- `bytcnt` register and `block_size` field of the `blksiz` register: set to 512†

The READ DMA EXT Command

The READ DMA EXT command reads a number of logical blocks of data from the card device using the Data-In data transfer protocol. The host uses a RW_REG command to issue the ATA command and the RW_BLK command for the data transfer.†

The WRITE DMA EXT Command

The WRITE DMA EXT command writes a number of logical blocks of data to the card device using the Data-Out data transfer protocol. The host uses a RW_REG command to issue the ATA command and the RW_BLK command for the data transfer.†

The STANDBY IMMEDIATE Command

This ATA command causes the card device to immediately enter the most aggressive power management mode that still retains internal device context. No data transfer (RW_BLK) is expected for this command.†

For card devices that do not provide a power savings mode, the STANDBY IMMEDIATE command returns a successful status indication. The host issues a RW_REG command for the ATA command, and the status is retrieved with the SD/SDIO CMD39 or RW_REG command. Only the status field of the ATA task file contains the success status; there is no error status.†

The host controller uses the following settings while sending the RW_REG command for the STANDBY IMMEDIATE ATA command: †

- `cmd` register setting: `data_expected` bit set to 0†
- `cmdarg` register settings: †
  - Bit [31] set to 1 †
  - Bits [7:2] set to 4 †
  - All other bits set to 0 †
- Task file settings: †
  - Command field of the ATA task file set to 0xE0†
  - Reserved fields of the task file set to 0†
- `bytcnt` register and `block_size` field of the `blksiz` register: set to 16 †

The FLUSH CACHE EXT Command

For card devices that buffer/cache written data, the FLUSH CACHE EXT command ensures that buffered data is written to the card media. For cards that do not buffer written data, the FLUSH CACHE EXT command returns a success status. No data transfer (RW_BLK) is expected for this ATA command. †

The host issues a RW_REG command for the ATA command, and the status is retrieved with the SD/SDIO CMD39 or RW_REG command. There can be error status for this ATA command, in which case fields other than the status field of the ATA task file are valid.†

The host controller uses the following settings while sending the RW_REG command for the STANDBY IMMEDIATE ATA command:†

- `cmd` register setting: `data_expected` bit set to 0 †
- `cmdarg` register settings: †
  - Bit [31] set to 1 †
  - Bits [7:2] set to 4†
  - All other bits set to 0†
- Task file settings: †
  - Command field of the ATA task file set to 0xEA †
  - Reserved fields of the task file set to 0†
- `bytcnt` register and `block_size` field of the `blksiz` register: set to 16 †

Card Read Threshold

When an application needs to perform a single or multiple block read command, the application must set the `cardthrctl` register with the appropriate card read threshold size in the card read threshold field (`cardrdthreshold`) and set the `cardrdthren` bit to 1. This additional information specified in the controller ensures that the controller sends a read command only if there is space equal to the card read threshold available in the RX FIFO buffer. This in turn ensures that the card clock is not stopped in the middle a block of data being transmitted from the card. Set the card read threshold to the block size of the transfer to guarantee there is a minimum of one block size of space in the RX FIFO buffer before the controller enables the card clock. †

The card read threshold is required when the round trip delay is greater than half of `sdmmc_clk_divided`.†

Table 14-36: Card Read Threshold Guidelines†

Bus Speed Modes	Round Trip Delay (Delay_R) (44)	Is Stopping of Card Clock Allowed?	Card Read Threshold Required?
SDR25	Delay_R > 0.5 * (`sdmmc_clk`/4)	No	Yes
	Delay_R < 0.5 * (`sdmmc_clk`/4)	Yes	No
SDR12	Delay_R > 0.5 * (`sdmmc_clk`/4)	No	Yes
	Delay_R < 0.5 * (`sdmmc_clk`/4)	Yes	No

Related Information

http://www.altera.com/literature/hb/arria-v/av_51002.pdf

(44) Delay_R = Delay_O + tODLY + Delay_I †

Where: †

Delay_O = `sdmmc_clk` to `sdmmc_cclk_out` delay (including I/O pin delay) †

Delay_I = Input I/O pin delay + routing delay to the input register †

tODLY = `sdmmc_cclk_out` to card output delay (varies across card manufactures and speed modes) †

For the delay numbers needed for above calculation, refer to Arria 10 Datasheet. †

Recommended Usage Guidelines for Card Read Threshold

1. The `cardthrctl` register must be set before setting the `cmd` register for a data read command.†
2. The `cardthrctl` register must not be set while a data transfer command is in progress.†
3. The `cardrdthreshold` field of the `cardthrctl` register must be set to at the least the block size of a single or multiblock transfer. A `cardrdthreshold` field setting greater than or equal to the block size of the read transfer ensures that the card clock does not stop in the middle of a block of data.†
4. If the round trip delay is greater than half of the card clock period, card read threshold must be enabled and the card threshold must be set as per guideline 3 to guarantee that the card clock does not stop in the middle of a block of data.†
5. If the `cardrdthreshold` field is set to less than the block size of the transfer, the host must ensure that the receive FIFO buffer never overflows during the read transfer. Overflow can cause the card clock from the controller to stop. The controller is not able to guarantee that the card clock does not stop during a read transfer.†

Note: If the `cardrdthreshold` field of the `cardthrctl` register, and the `rx_wmark` and `dw_dma_multiple_transaction_size` fields of the `fifoth` register are set incorrectly, the card clock might stop indefinitely, with no interrupts generated by the controller.†

Card Read Threshold Programming Sequence

Most cards, such as SDHC or SDXC, support block sizes that are either specified in the card or are fixed to 512 bytes. For SDIO, MMC, and standard capacity SD cards that support partial block read (READ_BL_PARTIAL set to 1 in the CSD register of the card device), the block size is variable and can be chosen by the application.†

To use the card read threshold feature effectively and to guarantee that the card clock does not stop because of a FIFO Full condition in the middle of a block of data being read from the card, follow these steps:†

1. Choose a block size that is a multiple of four bytes.†
2. Enable card read threshold feature. The card read threshold can be enabled only if the block size for the given transfer is less than or equal to the total depth of the FIFO buffer:†

   (block size / 4) ≤ 1024†
3. Choose the card read threshold value: †
   - If (block size / 4) ≥ 512, choose `cardrdthreshold` such that:†
     - `cardrdthreshold` ≤ (block size / 4) in bytes†
   - If (block size / 4) < 512, choose `cardrdthreshold` such that:†
     - `cardrdthreshold` = (block size / 4) in bytes†
4. Set the `dw_dma_multiple_transaction_size` field in the `fifoth` register to the number of transfers that make up a DMA transaction. For example, size = 1 means 4 bytes are moved. The possible values for the size are 1, 4, 8, 16, 32, 64, 128, and 256 transfers. Select the size so that the value (block size / 4) is evenly divided by the size.†
5. Set the `rx_wmark` field in the `fifoth` register to the size – 1.†

For example, if your block size is 512 bytes, legal values of `dw_dma_multiple_transaction_size` and `rx_wmark` are listed in the following table.

Table 14-37: Legal Values of dw_dma_multiple_transaction_size and rx_wmark for Block Size = 512†

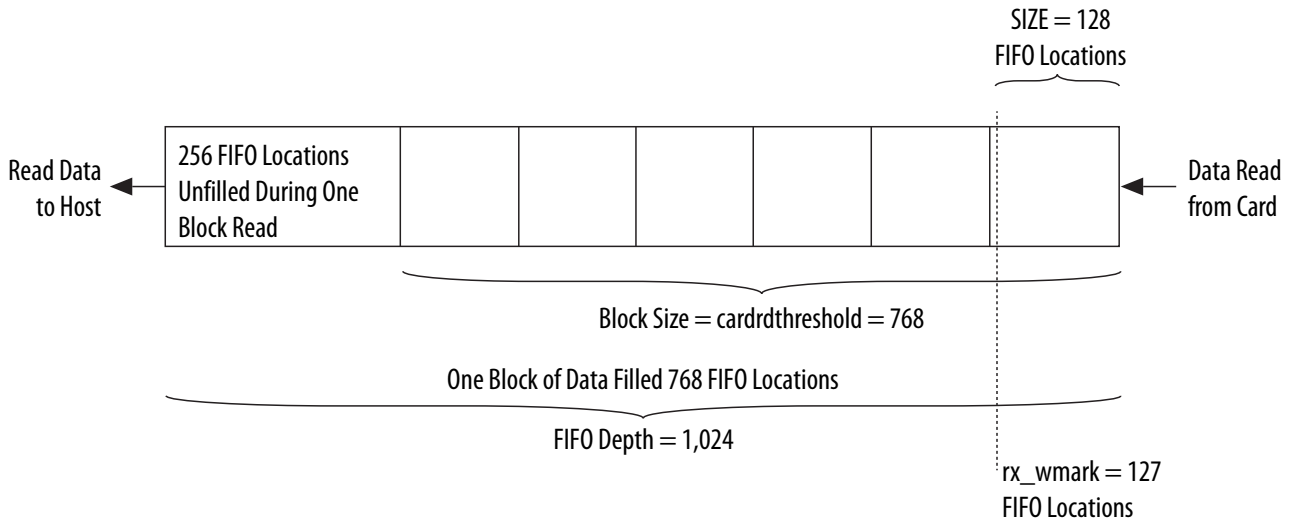
Block Size	dw_dma_multiple_transaction_size	rx_wmark
512	1	0
512	4	3
512	8	7
512	16	15
512	32	31
512	64	63
512	128	127

Card Read Threshold Programming Examples

This section shows examples of how to program the card read threshold.†

- Choose a block size that is a multiple of 4 (the number of bytes per FIFO location), and less than 4096 (1024 FIFO locations). For example, a block size of 3072 bytes is legal, because 3072 / 4 = 768 FIFO locations.†
- For DMA mode, choose the size so that block size is a multiple of the size. For example size = 128, where block size%size = 0.†
- Set the `rx_wmark` field = size – 1. For example, the `rx_wmark` field = 128 – 1 = 127.†
- Because block size > ½ FifoDepth, set the `cardrdthreshold` field to the block size. For example, the `cardrdthreshold` field = 3072 bytes.†

Figure 14-13: FIFO Buffer content when Card Read Threshold is set to 768†



Interrupt and Error Handling

This section describes how to use interrupts to handle errors. On power-on or reset, interrupts are disabled (the `int_enable` bit in the `ctrl` register is set to 0), and all the interrupts are masked (the `intmask` register default is 0). The controller error handling includes the following types of errors:

- Response and data timeout errors—For response time-outs, the host software can retry the command. For data time-outs, the controller has not received the data start bit from the card, so software can either retry the whole data transfer again or retry from a specified block onwards. By reading the contents of the `tcbcnt` register later, the software can decide how many bytes remain to be copied (read). †
- Response errors—Set to 1 when an error is received during response reception. If the response received is invalid, the software can retry the command. †
- Data errors—Set to 1 when a data receive error occurs. Examples of data receive errors: †
  - Data CRC†
  - Start bit not found †
  - End bit not found †

  These errors can be occur on any block. On receipt of an error, the software can issue an SD/SDIO STOP or SEND_IF_COND command, and retry the command for either the whole data or partial data.†
- Hardware locked error—Set to 1 when the controller cannot load a command issued by software. When software sets the `start_cmd` bit in the `cmd` register to 1, the controller tries to load the command. If the command buffer already contains a command, this error is raised, and the new command is discarded, requiring the software to reload the command.†
- FIFO buffer underrun/overrun error—If the FIFO buffer is full and software tries to write data to the FIFO buffer, an overrun error is set. Conversely, if the FIFO buffer is empty and the software tries to read data from the FIFO buffer, an underrun error is set. Before reading or writing data in the FIFO buffer, the software must read the FIFO buffer empty bit (`fifo_empty`) or FIFO buffer full bit (`fifo_full`) in the `status` register.†
- Data starvation by host timeout—This condition occurs when software does not service the FIFO buffer fast enough to keep up with the controller. Under this condition and when a read transfer is in process, the software must read data from the FIFO buffer, which creates space for further data reception. When a transmit operation is in process, the software must write data to fill the FIFO buffer so that the controller can write the data to the card.†
- CE-ATA errors†
- CRC error on command—If a CRC error is detected for a command, the CE-ATA card device does not send a response, and a response timeout is expected from the controller. The ATA layer is notified that an MMC transport layer error occurred.

- CRC error on command—If a CRC error is detected for a command, the CE-ATA card device does not send a response, and a response timeout is expected from the controller. The ATA layer is notified that an MMC transport layer error occurred.†
- Write operation—Any MMC transport layer error known to the card device causes an outstanding ATA command to be terminated. The ERR bits are set in the ATA status registers and the appropriate error code is sent to the Error Register (Error) on the ATA card device.†

  If the device interrupt bit of the CE-ATA card (the nIEN bit in the ATA control register) is set to 0, the CCS is sent to the host.†

  If the device interrupt bit is set to 1, the card device completes the entire data unit count if the host controller does not abort the ongoing transfer.†

  Note: During a multiple-block data transfer, if a negative CRC status is received from the card device, the data path signals a data CRC error to the BIU by setting the `dcrc` bit in the `rintsts` register to 1. It then continues further data transmission until all the bytes are transmitted.†
- Read operation—If MMC transport layer errors are detected by the host controller, the host completes the ATA command with an error status. The host controller can issue a CCSD command followed by a STOP_TRANSMISSION (CMD12) command to abort the read transfer. The host can also transfer the entire data unit count bytes without aborting the data transfer.†

Booting Operation for eMMC and MMC

This section describes how to set up the controller for eMMC and MMC boot operation.

Note: The BootROM and initial software do not use the boot partitions that are in the MMC card. This means that there is no boot partition support of the SD/MMC controller.

Boot Operation by Holding Down the CMD Line

The controller can boot from MMC4.3, MMC4.4, and MMC4.41 cards by holding down the CMD line.

For information about this boot method, refer to the following specifications, available on the JEDEC website:

- JEDEC Standard No. 84-A441
- JEDEC Standard No. 84-A44
- JEDEC Standard No. JESD84-A43

Related Information

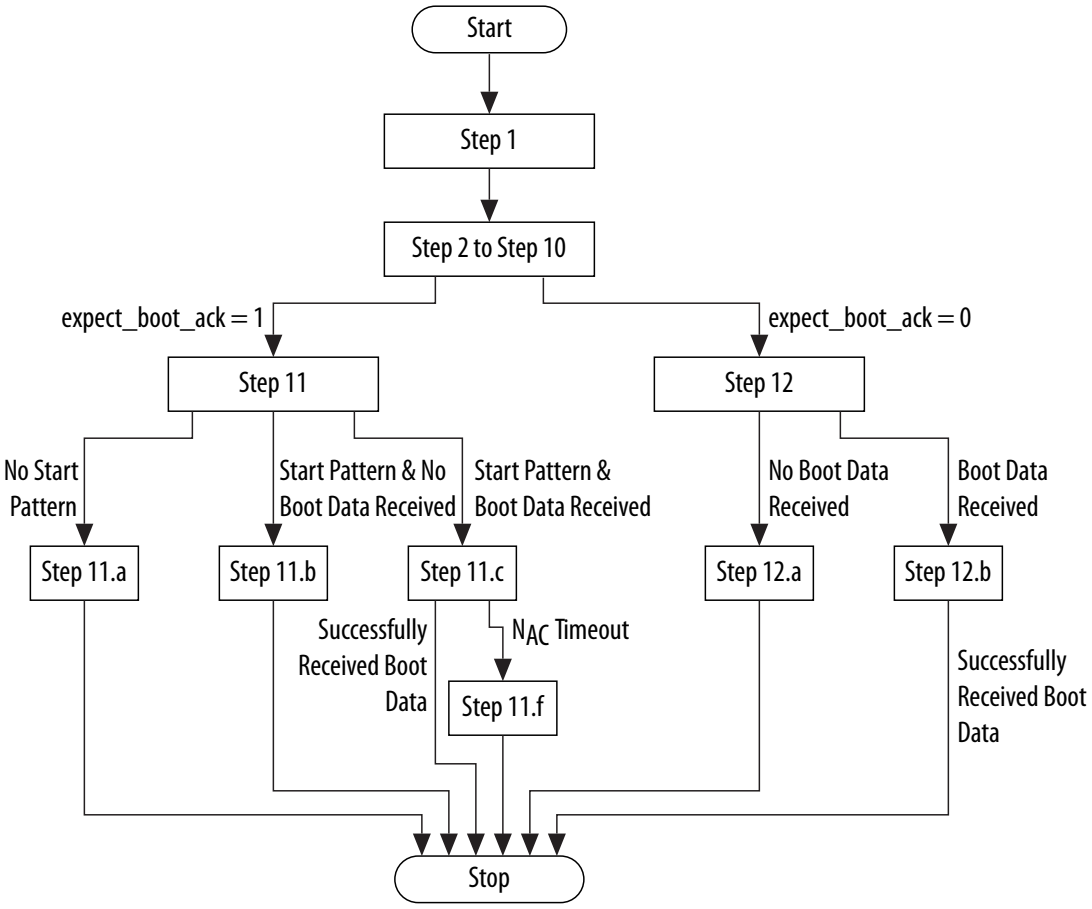
www.jedec.org

For more information about this boot method, refer to the following JEDEC Standards available on the JEDEC website: No. 84-A441, No. 84-A44, and No. JESD84-A43.

Boot Operation for eMMC Card Device

The following figure illustrates the steps to perform the boot process for eMMC card devices. The detailed steps are described following the flow chart.

Figure 14-14: Flow for eMMC Boot Operation†



1. The software driver performs the following checks: †
   - If the eMMC card device supports boot operation (the BOOT_PARTITION_ENABLE bit is set to 1 in the EXT_CSD register of the eMMC card).†
   - The BOOT_SIZE_MULT and BOOT_BUS_WIDTH values in the EXT_CSD register, to be used during the boot process.†
2. The software sets the following bits: †
   - Sets masks for interrupts, by setting the appropriate bits to 0 in the `intmask` register.†
   - Sets the global `int_enable` bit of the `ctrl` register to 1. Other bits in the `ctrl` register must be set to 0. †

   Note: Altera recommends that you write 0xFFFFFFFF to the `rintsts` and `idsts` registers to clear any pending interrupts before setting the `int_enable` bit. For internal DMA controller mode, the software driver needs to unmask all the relevant fields in the `idinten` register.†
3. If the software driver needs to use the internal DMA controller to transfer the boot data received, it must perform the following steps: †

- Set up the descriptors as described in *Internal DMA Controller Transmission Sequences* and *Internal DMA Controller Reception Sequences*". †
- Set the `use_internal_dmac` bit of the `ctrl` register to 1.†

4. Set the card device frequency to 400 kHz using the `clkdiv` registers. For more information, refer to Clock Setup.†
5. Set the `data_timeout` field of the `tmout` register equal to the card device total access time, N_{AC}. †
6. Set the `blksiz` register to 0x200 (512 bytes). †
7. Set the `bytcnt` register to a multiple of 128 KB, as indicated by the BOOT_SIZE_MULT value in the card device.†
8. Set the `rx_wmark` field in the `fifoth` register. Typically, the threshold value can be set to 512, which is half the FIFO buffer depth.†
9. Set the following fields in the `cmd` register:†
   - Initiate the command by setting `start_cmd` = 1†
   - Enable boot (`enable_boot`) = 1†
   - Expect boot acknowledge (`expect_boot_ack`): †
     - If a start-acknowledge pattern is expected from the card device, set `expect_boot_ack` to 1.†
     - If a start-acknowledge pattern is not expected from the card device, set `expect_boot_ack` to 0.†
   - Card number (`card_number`) = 0†
   - `data_expected` = 1†
   - Reset the remainder of `cmd` register bits to 0†
10. If no start-acknowledge pattern is expected from the card device (`expect_boot_ack` set to 0) proceed to **step 12**.†
11. This step handles the case where a start-acknowledge pattern is expected (`expect_boot_ack` was set to 1 in **step 9**).†
    a. If the Boot ACK Received interrupt is not received from the controller within 50 ms of initiating the command (**step 9**), the software driver must set the following `cmd` register fields: †
       - `start_cmd` = 1†
       - Disable boot (`disable_boot`)= 1†
       - `card_number` = 0 †
       - All other fields = 0†

       The controller generates a Command Done interrupt after deasserting the `CMD` pin of the card interface.†

       If internal DMA controller mode is used for the boot process, the controller performs the following steps after the Boot ACK Received timeout:†
       - The DMA descriptor is closed.†
       - The `ces` bit in the `idsts` register is set, indicating the Boot ACK Received timeout.†
       - The `ri` bit of the `idsts` register is not set.†

    b. If the Boot ACK Received interrupt is received, the software driver must clear this interrupt by writing 1 to the `ces` bit in the `idsts` register.†

       Within 0.95 seconds of the Boot ACK Received interrupt, the Boot Data Start interrupt must be received from the controller. If this does not occur, the software driver must write the following `cmd` register fields:†
       - `start_cmd` = 1†
       - disable_boot = 1†
       - card_number = 0†
       - All other fields = 0†

The controller generates a Command Done interrupt after deasserting the CMD pin of the card interface.†

If internal DMA controller mode is used for the boot process, the controller performs the following steps after the Boot ACK Received timeout:†

- The DMA descriptor is closed†
- The ces bit in the idsts register is set, indicating Boot Data Start timeout†
- The ri bit of the idsts register is not set†

c. If the Boot Data Start interrupt is received, it indicates that the boot data is being received from the card device. When the DMA engine is not in internal DMA controller mode, the software driver can then initiate a data read from the controller based on the rxdr interrupt bit in the rintsts register.†

In internal DMA controller mode, the DMA engine starts transferring the data from the FIFO buffer to the system memory as soon as the level set in the rx_wmark field of the fifoth register is reached.†

At the end of a successful boot data transfer from the card, the following interrupts are generated:†

- The cmd bit and dto bit in the rintsts register†
- The ri bit in the idsts register, in internal DMA controller mode only†

d. If an error occurs in the boot ACK pattern (0b010) or an EBE occurs: †

- The controller automatically aborts the boot process by pulling the CMD line high†
- The controller generates a Command Done interrupt†
- The controller does not generate a Boot ACK Received interrupt†
- The application aborts the boot transfer†

e. In internal DMA controller mode:†

- If the software driver creates more descriptors than required by the received boot data, the extra descriptors are not closed by the controller. Software cannot reuse the descriptors until they are closed.†
- If the software driver creates fewer descriptors than required by the received boot data, the controller generates a Descriptor Unavailable interrupt and does not transfer any further data to system memory.†

f. If N_{AC} is violated between data block transfers, the DRTO interrupt is asserted. In addition, if there is an error associated with the start or end bit, the SBE or EBE interrupt is also generated.†

The boot operation for eMMC card devices is complete. Do not execute the remaining (**step 12**).†

12. This step handles the case where no start-acknowledge pattern is expected (expect_boot_ack was set to 0 in **step 9**).†

a. If the Boot Data Start interrupt is not received from the controller within 1 second of initiating the command (**step 9**), the software driver must write the cmd register with the following fields:†

- start_cmd = 1†
- disable_boot = 1†
- card_number = 0†
- All other fields = 0†

The controller generates a Command Done interrupt after deasserting the CMD line of the card. In internal DMA controller mode, the descriptor is closed and the ces bit in the idsts register is set to 1, indicating a Boot Data Start timeout.†

b. If a Boot Data Start interrupt is received, it indicates that the boot data is being received from the card device. When the DMA engine is not in internal DMA controller mode, the software driver

can then initiate a data read from the controller based on the `rxdr` interrupt bit in the `rintsts` register.†

In internal DMA controller mode, the DMA engine starts transferring the data from the FIFO buffer to the system memory as soon as the level specified in the `rx_wmark` field of the `fifoth` register is reached.†

At the end of a successful boot data transfer from the card, the following interrupts are generated:†

- The `cmd` bit and `dto` bit in the `rintsts` register†
- The `ri` bit in the `idsts` register, in internal DMA controller mode only†

c. In internal DMA controller mode:†

- If the software driver creates more descriptors than required by the received boot data, the extra descriptors are not closed by the controller.†
- If the software driver creates fewer descriptors than required by the received boot data, the controller generates a Descriptor Unavailable interrupt and does not transfer any further data to system memory.†

The boot operation for eMMC card devices is complete.†

Boot Operation for Removable MMC4.3, MMC4.4 and MMC4.41 Cards

Removable MMC4.3, MMC4.4, and MMC4.41 Differences

Removable MMC4.3, MMC4.4, and MMC4.41 cards differ with respect to eMMC in that the controller is not aware whether these cards support the boot mode of operation when plugged in. Thus, the controller must: †

1. Discover these cards as it would discover MMC4.0/4.1/4.2 cards for the first time†
2. Know the card characteristics †
3. Decide whether to perform a boot operation or not†

Booting Removable MMC4.3, MMC4.4 and MMC4.41 Cards

For removable MMC4.3, MMC4.4 and MMC4.41 cards, the software driver must perform the following steps:†

1. Discover the card as described in *Enumerated Card Stack*.†
2. Read the EXT_CSD register of the card and examine the following fields: †
   - BOOT_PARTITION_ENABLE †
   - BOOT_SIZE_MULT†
   - BOOT_INFO †
3. If necessary, the software can manipulate the boot information in the card. †

Note: For more information, refer to "Access to Boot Partition" in the following specifications available on the JEDEC website:

- JEDEC Standard No. 84-A441
- JEDEC Standard No. 84-A44
- JEDEC Standard No. JESD84-A43

4. If the host processor needs to perform a boot operation at the next power-up cycle, it can manipulate the EXT_CSD register contents by using a SWITCH_FUNC command. †
5. After this step, the software driver must power down the card by writing to the `pwren` register. †
6. From here on, use the same steps as in *Alternative Boot Operation for eMMC Card Devices*.†

Related Information

- **Enumerated Card Stack** on page 14-40
  Refer to this section for more information on discovering removable MMC cards.
- **http://www.jedec.org**
- **Alternative Boot Operation for eMMC Card Devices** on page 14-76
  Refer to this section for information about alternative boot operation steps.

Alternative Boot Operation

The alternative boot operation differs from the previous boot operation in that software uses the SD/SDIO GO_IDLE_STATE command to boot the card, rather than holding down the CMD line of the card. The alternative boot operation can be performed only if bit 0 in the BOOT_INFO register is set to 1. BOOT_INFO is located at offset 228 in the EXT_CSD registers. †

For detailed information about alternative boot operation, refer to the following specifications available on the JEDEC website:

- JEDEC Standard No. 84-A441
- JEDEC Standard No. 84-A44
- JEDEC Standard No. JESD84-A43

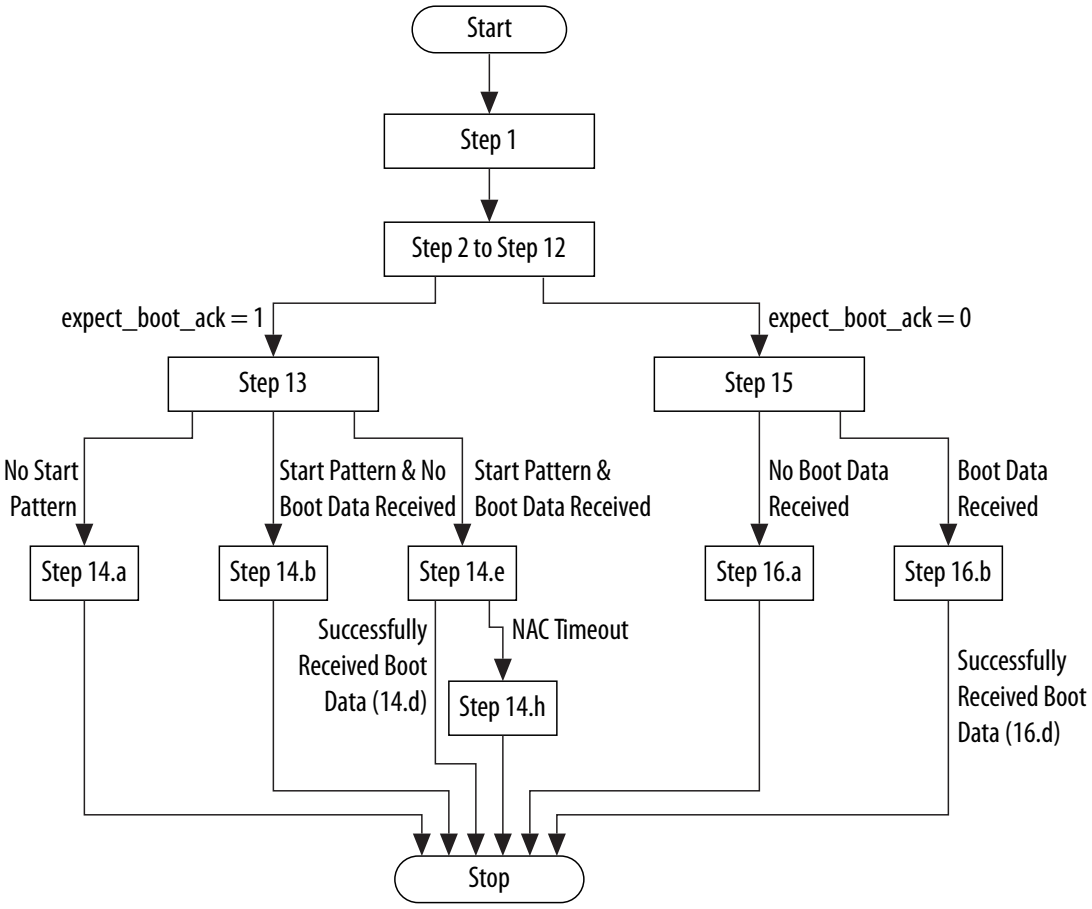
Related Information

www.jedec.org
For more information about alternative boot operation, refer to the following JEDEC Standards available on the JEDEC website: No. 84-A441, No. 84-A44, and No. JESD84-A43.

Alternative Boot Operation for eMMC Card Devices

The following figure illustrates the sequence of steps required to perform the alternative boot operation for eMMC card devices. The detailed steps are described following the flow chart.

Figure 14-15: Flow for eMMC Alternative Boot Operation†



1. The software driver checks:†
   - If the eMMC card device supports alternative boot operation (the BOOT_INFO bit is set to 1 in the eMMC card).†
   - The BOOT_SIZE_MULT and BOOT_BUS_WIDTH values in the card device to use during the boot process.†
2. The software sets the following bits: †
   - Sets masks for interrupts by resetting the appropriate bits to 0 in the `intmask` register.†
   - Sets the `int_enable` bit of the `ctrl` register to 1. Other bits in the `ctrl` register must be set to 0. †

     Note: Altera recommends writing 0xFFFFFFFF to the `rintsts` register and `idsts` register to clear any pending interrupts before setting the `int_enable` bit. For internal DMA controller mode, the software driver needs to unmask all the relevant fields in the `idinten` register.†
3. If the software driver needs to use the internal DMA controller to transfer the boot data received, it must perform the following actions: †
   - Set up the descriptors as described in *Internal DMA Controller Transmission Sequences* and *Internal DMA Controller Reception Sequences*. †
   - Set the use internal DMAC bit (`use_internal_dmac`) of the `ctrl` register to 1. †
4. Set the card device frequency to 400 kHz using the `clkdiv` registers. For more information, refer to *Clock Setup*. Ensure that the card clock is running.†

5. Wait for a time that ensures that at least 74 card clock cycles have occurred on the card interface.†
6. Set the `data_timeout` field of the `tmout` register equal to the card device total access time, N_{AC}. †
7. Set the `blksiz` register to 0x200 (512 bytes).†
8. Set the `bytcnt` register to multiples of 128K bytes, as indicated by the BOOT_SIZE_MULT value in the card device.†
9. Set the `rx_wmark` field in the `fifoth` register. Typically, the threshold value can be set to 512, which is half the FIFO buffer depth.†
10. Set the `cmdarg` register to 0xFFFFFFFA. †
11. Initiate the command, by setting the `cmd` register with the following fields: †
    - `start_cmd` = 1†
    - `enable_boot` = 1†
    - `expect_boot_ack`:†
      - If a start-acknowledge pattern is expected from the card device, set `expect_boot_ack` to 1.†
      - If a start-acknowledge pattern is not expected from the card device, set `expect_boot_ack` to 0. †
    - `card_number` = 0 †
    - `data_expected` = 1†
    - `cmd_index` = 0†
    - Set the remainder of `cmd` register bits to 0.†
12. If no start-acknowledge pattern is expected from the card device (`expect_boot_ack` set to 0) jump to **step 15**. †
13. Wait for the Command Done interrupt.†
14. This step handles the case where a start-acknowledge pattern is expected (`expect_boot_ack` was set to 1 in **step 11**).†
    a. If the Boot ACK Received interrupt is not received from the controller within 50 ms of initiating the command (**step 11**), the start pattern was not received. The software driver must discontinue the boot process and start with normal discovery. †

       If internal DMA controller mode is used for the boot process, the controller performs the following steps after the Boot ACK Received timeout:†
       - The DMA descriptor is closed.†
       - The `ces` bit in the `idsts` register is set to 1, indicating the Boot ACK Received timeout.†
       - The `ri` bit of the `idsts` register is not set.†

    b. If the Boot ACK Received interrupt is received, the software driver must clear this interrupt by writing 1 to it. †

       Within 0.95 seconds of the Boot ACK Received interrupt, the Boot Data Start interrupt must be received from the controller. If this does not occur, the software driver must discontinue the boot process and start with normal discovery.†

       If internal DMA controller mode is used for the boot process, the controller performs the following steps after the Boot ACK Received timeout: †
       - The DMA descriptor is closed.†
       - The `ces` bit in the `idsts` register is set to 1, indicating Boot Data Start timeout.†
       - The `ri` bit of the `idsts` register is not set.†

    c. If the Boot Data Start interrupt is received, it indicates that the boot data is being received from the card device. When the DMA engine is not in internal DMA controller mode, the software driver can then initiate a data read from the controller based on the `rxdr` interrupt bit in the `rintsts` register.†

In internal DMA controller mode, the DMA engine starts transferring the data from the FIFO buffer to the system memory as soon as the level specified in the `rx_wmark` field of the `fifoth` register is reached. †

d. The software driver must terminate the boot process by instructing the controller to send the SD/SDIO GO_IDLE_STATE command:†

- Reset the `cmdarg` register to 0.†
- Set the `start_cmd` bit of the `cmd` register to 1, and all other bits to 0.†

e. At the end of a successful boot data transfer from the card, the following interrupts are generated: †

- The `cmd` bit and `dto` bit in the `rintsts` register†
- The `ri` bit in the `idsts` register, in internal DMA controller mode only†

f. If an error occurs in the boot ACK pattern (0b010) or an EBE occurs: †

- The controller does not generate a Boot ACK Received interrupt. †
- The controller detects Boot Data Start and generates a Boot Data Start interrupt. †
- The controller continues to receive boot data. †
- The application must abort the boot process after receiving a Boot Data Start interrupt.†

g. In internal DMA controller mode: †

- If the software driver creates more descriptors than required by the received boot data, the extra descriptors are not closed by the controller. †
- If the software driver creates fewer descriptors than required by the received boot data, the controller generates a Descriptor Unavailable interrupt and does not transfer any further data to system memory.†

h. If N_{AC} is violated between data block transfers, a DRTO interrupt is asserted. Apart from this, if there is an error associated with the start or end bit, the SBE or EBE interrupt is also generated.†

The alternative boot operation for eMMC card devices is complete. Do not execute the remaining steps (**15** and **16**). †

15. Wait for the Command Done interrupt.†

16. This step handles the case where a start-acknowledge pattern is not expected (`expect_boot_ack` was set to 0 in **step 11**). †

a. If the Boot Data Start interrupt is not received from the controller within 1 second of initiating the command (**step 11**), the software driver must discontinue the boot process and start with normal discovery. † In internal DMA controller mode:†

- The DMA descriptor is closed.†
- The `ces` bit in the `idsts` register is set to 1, indicating Boot Data Start timeout.†
- The `ri` bit of the `idsts` register is not set.†

b. If a Boot Data Start interrupt is received, the boot data is being received from the card device. When the DMA engine is not in internal DMA controller mode, the software driver can then initiate a data read from the controller based on the `rxdr` interrupt bit in the `rintsts` register.†

In internal DMA controller mode, the DMA engine starts transferring the data from the FIFO buffer to the system memory as soon as the level specified in the `rx_wmark` field of the `fifoth` register is reached.†

c. The software driver must terminate the boot process by instructing the controller to send the SD/SDIO GO_IDLE_STATE (CMD0) command: †

- Reset the `cmdarg` register to 0.†
- Set the `start_cmd` bit in the `cmd` register to 1, and all other bits to 0.†

d. At the end of a successful boot data transfer from the card, the following interrupts are generated: †

- The `cmd` bit and `dto` bit in the `rintsts` register†
- The `ri` bit in the `idsts` register, in internal DMA controller mode only †

e. In internal DMA controller mode: †

- If the software driver creates more descriptors than required by the received boot data, the extra descriptors are not closed by the controller. †
- If the software driver creates fewer descriptors than required by the received boot data, the controller generates a Descriptor Unavailable interrupt and does not transfer any further data to system memory.†

The alternative boot operation for eMMC card devices is complete.†

Alternative Boot Operation for MMC4.3 Cards

Removable MMC4.3 Boot Mode Support

Removable MMC4.3 cards differ with respect to eMMC in that the controller is not aware whether these cards support the boot mode of operation. Thus, the controller must: †

1. Discover these cards as it would discover MMC4.0/4.1/4.2 cards for the first time †
2. Know the card characteristics †
3. Decide whether to perform a boot operation or not†

Discovering Removable MMC4.3 Boot Mode Support

For removable MMC4.3 cards, the software driver must perform the following steps: †

1. Discover the card as described in *Enumerated Card Stack*.†
2. Read the MMC card device's EXT_CSD registers and examine the following fields: †
   - BOOT_PARTITION_ENABLE †
   - BOOT_SIZE_MULT †
   - BOOT_INFO †

   Note: For more information, refer to "Access to Boot Partition" in JEDEC Standard No. JESD84-A43, available on the JEDEC website.†
3. If the host processor needs to perform a boot operation at the next power-up cycle, it can manipulate the contents of the EXT_CSD registers in the MMC card device, by using a SWITCH_FUNC command. †
4. After this step, the software driver must power down the card by writing to the `pwren` register. †
5. From here on, use the same steps as in *Alternative Boot Operation for eMMC Card Devices*. †

   Note: Ignore the EBE if it is generated during an abort scenario.

   If a boot acknowledge error occurs, the boot acknowledge received interrupt times out. †

In internal DMA controller mode, the application needs to depend on the descriptor close interrupt instead of the data done interrupt. †

ctrl Fields

Bit	Name	Description	Access	Reset
25	use_internal_dmac	Enable and Disable Internal DMA transfers. **Value** **Description** 0x0 The host performs data transfers thru slave interface 0x1 Internal DMAC used for data transfer	RW	0x0
11	ceata_device_interrupt_status	Software should appropriately write to this bit after power-on reset or any other reset to CE-ATA device. After reset, usually CE-ATA device interrupt is disabled (nIEN = 1). If the host enables CE-ATA device interrupt, then software should set this bit. **Value** **Description** 0x0 Interrupts not enabled in CE-ATA device 0x1 Interrupts are enabled in CE-ATA device	RW	0x0
10	send_auto_stop_ccsd	Always set send_auto_stop_ccsd and send_ccsd bits together; send_auto_stop_ccsd should not be set independent of send_ccsd. When set, SD/MMC automatically sends internally generated STOP command (CMD12) to CE-ATA device. After sending internally-generated STOP command, Auto Command Done (ACD) bit in RINTSTS is set and generates interrupt to host if Auto CommandDone interrupt is not masked. After sending the CCSD, SD/MMC automatically clears send_auto_stop_ccsd bit. **Value** **Description** 0x0 Clear bit if SD/MMC does not reset the bit 0x1 Send internally generated STOP.	RW	0x0

Bit	Name	Description	Access	Reset
9	send_ccsd	When set, SD/MMC sends CCSD to CE-ATA device. Software sets this bit only if current command is expecting CCS (that is, RW_BLK) and interrupts are enabled in CE-ATA device. Once the CCSD pattern is sent to device, SD/MMC automatically clears send_ccsd bit. It also sets Command Done (CD) bit in RINTSTS register and generates interrupt to host if Command Done interrupt is not masked. NOTE: Once send_ccsd bit is set, it takes two card clock cycles to drive the CCSD on the CMD line. Due to this, during the boundary conditions it may happen that CCSD is sent to the CE-ATA device, even if the device signalled CCS. **Value** — **Description** 0x0 — Clear bit if SD/MMC does not reset the bit 0x1 — Send Command Completion Signal Disable (CCSD) to CE-ATA device	RW	0x0
8	abort_read_data	After suspend command is issued during read-transfer, software polls card to find when suspend happened. Once suspend occurs software sets bit to reset data state-machine, which is waiting for next block of data. Bit automatically clears once data statemachine resets to idle. Used in SDIO card suspend sequence. **Value** — **Description** 0x0 — No change 0x1 — Abort Read	RW	0x0
7	send_irq_response	Bit automatically clears once response is sent. To wait for MMC card interrupts, host issues CMD40, and SD/MMC waits for interrupt response from MMC card(s). In meantime, if host wants SD/MMC to exit waiting for interrupt state, it can set this bit, at which time SD/MMC command state-machine sends CMD40 response on bus and returns to idle state. **Value** — **Description** 0x0 — No change 0x1 — Send auto IRQ response	RW	0x0

Bit	Name	Description	Access	Reset
6	read_wait	For sending read-wait to SDIO cards. **Value** **Description** 0x0 Read Wait 0x1 Assert Read Wait	RW	0x0
4	int_enable	This bit enables and disable interrupts if one or more unmasked interrupts are set. **Value** **Description** 0x0 Disable Interrupts 0x1 Enable interrupts	RW	0x0
2	dma_reset	This bit resets the DMA interface control logic **Value** **Description** 0x0 No change 0x1 Reset internal DMA interface control logic	RW	0x0
1	fifo_reset	This bit resets the FIFO. This bit is auto-cleared after completion of reset operation. **Value** **Description** 0x0 No change 0x1 Reset to data FIFO To reset FIFO pointers	RW	0x0
0	controller_reset	This bit resets the controller. This bit is auto-cleared after two l4_mp_clk and two sdmmc_clk clock cycles. This resets: - BIU/CIU interface - CIU and state machines - abort_read_data, send_irq_response, and read_wait bits of control register -start_cmd bit of command register Does not affect any registers, DMA interface, FIFO or host interrupts. **Value** **Description** 0x0 No change -default 0x1 Reset SD/MMC controller	RW	0x0

pwren

Power on/off switch for card; once power is turned on, firmware should wait for regulator/switch ramp-up time before trying to initialize card.

Module Instance	Base Address	Register Address
sdmmc	0xFF704000	0xFF704004

Offset: 0x4

Access: RW

Bit Fields

block_size RW 0x200															

blksiz Fields

Bit	Name	Description	Access	Reset
15:0	block_size	The size of a block in bytes.	RW	0x200

bytcnt

The number of bytes to be transferred.

Module Instance	Base Address	Register Address
sdmmc	0xFF704000	0xFF704020

Offset: 0x20

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
byte_count RW 0x200															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
byte_count RW 0x200															

bytcnt Fields

Bit	Name	Description	Access	Reset
31:0	byte_count	This value should be an integer multiple of the Block Size for block transfers. For undefined number of byte transfers, byte count should be set to 0. When byte count is set to 0, it is responsibility of host to explicitly send stop/abort command to terminate data transfer. Note: In SDIO mode, if a single transfer is greater than 4 bytes and non-DWORD-aligned, the transfer should be broken where only the last transfer is non-DWORD-aligned and less than 4 bytes. For example, if a transfer of 129 bytes must occur, then the driver should start at least two transfers; one with 128 bytes and the other with 1 byte.	RW	0x200

intmask

Allows Masking of Various Interrupts

Module Instance	Base Address	Register Address
sdmmc	0xFF704000	0xFF704024

Offset: 0x24

Access: RW

Bit Fields

cmd Fields

Bit	Name	Description	Access	Reset
31	start_cmd	Once command is taken by CIU, bit is cleared. If Start Cmd issued host should not attempt to write to any command registers. If write is attempted, hardware lock error is set in raw interrupt register. Once command is sent and response is received from SD_MMC_CEATA cards, Command Done bit is set in raw interrupt register. **Value** — **Description** 0x0 — No Start Cmd 0x1 — Start Cmd Issued	RW	0x0
29	use_hold_reg	Set to one for SDR12 and SDR25 (with non-zero phase-shifted cclk_in_drv); zero phase shift is not allowed in these modes. -Set to 1'b0 for SDR50, SDR104, and DDR50 (with zero phase-shifted cclk_in_drv). -Set to 1'b1 for SDR50, SDR104, and DDR50 (with non-zero phase-shifted cclk_in_drv). **Value** — **Description** 0x0 — CMD and DATA sent to card bypassing HOLD Register 0x1 — CMD and DATA sent to card through the HOLD Register	RW	0x1

Bit	Name	Description	Access	Reset
28	volt_switch	Voltage switch bit. When set must be set for CMD11 only. **Value** **Description** 0x0 No voltage switching - default 0x1 Voltage switching enabled	RW	0x0
27	boot_mode	Type of Boot Mode. **Value** **Description** 0x0 Mandatory Boot Operation 0x1 Alternate Boot Operation	RW	0x0
26	disable_boot	When software sets this bit along with start_cmd, CIU terminates the boot operation. Do NOT set disable_boot and enable_boot together. **Value** **Description** 0x0 Boot not Terminated 0x1 Terminate Boot	RW	0x0
25	expect_boot_ack	When Software sets this bit along with enable_boot, CIU expects a boot acknowledge start pattern of 0-1-0 from the selected card. **Value** **Description** 0x0 No Boot ACK 0x1 Expect Boot ACK	RW	0x0
24	enable_boot	This bit should be set only for mandatory boot mode. When Software sets this bit along with start_cmd, CIU starts the boot sequence for the corresponding card by asserting the CMD line low. Do NOT set disable_boot and enable_boot together **Value** **Description** 0x0 Disable Boot 0x1 Enable Boot	RW	0x0

Bit	Name	Description	Access	Reset
23	ccs_expected	If the command expects Command Completion Signal (CCS) from the CE-ATA device, the software should set this control bit. SD/MMC sets Data Transfer Over (DTO) bit in RINTSTS register and generates interrupt to host if Data Transfer Over interrupt is not masked. **Value** — **Description** 0x0 — Interrupts are not enabled in CE-ATA device (nIEN = 1 in ATA control register), or command does not expect CCS from device 0x1 — Interrupts are enabled in CE-ATA device (nIEN = 0), and RW_BLK command expects command completion signal from CE-ATA device	RW	0x0
22	read_ceata_device	Software should set this bit to indicate that CE-ATA device is being accessed for read transfer. This bit is used to disable read data timeout indication while performing CE-ATA read transfers. Maximum value of I/O transmission delay can be no less than 10 seconds. SD/MMC should not indicate read data timeout while waiting for data from CE-ATA device. **Value** — **Description** 0x0 — Host is not performing read access (RW_REG or RW_BLK) towards CE-ATA device 0x1 — Host is performing read access (RW_REG or RW_BLK) towards CE-ATA device	RW	0x0

Bit	Name	Description	Access	Reset
21	update_clock_registers_only	Following register values transferred into card clock domain: CLKDIV, CLRSRC, CLKENA. Changes card clocks (change frequency, truncate off or on, and set low-frequency mode); provided in order to change clock frequency or stop clock without having to send command to cards. During normal command sequence, when update_clock_registers_only = 0, following control registers are transferred from BIU to CIU: CMD, CMDARG, TMOUT, CTYPE, BLKSIZ, BYTCNT. CIU uses new register values for new command sequence to card(s). When bit is set, there are no Command Done interrupts because no command is sent to SD_MMC_CEATA cards. **Value** **Description** 0x0 Normal command sequence 0x1 Do not send commands, just update clock register value into card clock domain	RW	0x0
20:16	card_number	Card number in use must always be 0.	RW	0x0
15	send_initialization	After power on, 80 clocks must be sent to the card for initialization before sending any commands to card. Bit should be set while sending first command to card so that controller will initialize clocks before sending command to card. This bit should not be set for either of the boot modes (alternate or mandatory). **Value** **Description** 0x0 Do not send initialization sequence (80 clocks of 1) before sending this command 0x1 Send initialization sequence before sending this command	RW	0x0

Bit	Name	Description	Access	Reset
14	stop_abort_cmd	When open-ended or predefined data transfer is in progress, and host issues stop or abort command to stop data transfer, bit should be set so that command/data state-machines of CIU can return correctly to idle state. This is also applicable for Boot mode transfers. To Abort boot mode, this bit should be set along with CMD[26] = disable_boot. Note: If abort is sent to function-number currently selected or not in data-transfer mode, then bit should be set to 0. **Value** **Description** 0x0 Don't stop or abort command to stop current data transfer in progress 0x1 Stop or Abort command, intended to stop current data transfer in progress	RW	0x0
13	wait_prvdata_complete	Determines when command is sent. The send command at once option is typically used to query status of card during data transfer or to stop current data transfer. **Value** **Description** 0x0 Send command at once 0x1 Wait for previous data transfer completion	RW	0x0
12	send_auto_stop	When set, SD/MMC sends stop command to SD_MMC_CEATA cards at end of data transfer. Determine the following: *-when send_auto_stop bit should be set, since some data transfers do not need explicit stop commands. *-open-ended transfers that software should explicitly send to stop command. Additionally, when resume is sent to resume-suspended memory access of SD-Combo card, bit should be set correctly if suspended data transfer needs send_auto_stop. Don't care if no data expected from card. **Value** **Description** 0x0 No stop command sent at end of data transfer 0x1 Send stop command at end of data transfer	RW	0x0

Bit	Name	Description	Access	Reset
11	transfer_mode	Block transfer command. Don't care if no data expected **Value** **Description** 0x0 Block data transfer command 0x1 Stream data transfer command	RW	0x0
10	read_write	Read/Write from card. Don't care if no data transfer expected. **Value** **Description** 0x0 Read from card 0x1 Write to card	RW	0x0
9	data_expected	Set decision on data transfer expecetd or not. **Value** **Description** 0x0 No data transfer expected (read/write) 0x1 Data transfer expected (read/write)	RW	0x0
8	check_response_crc	Some of command responses do not return valid CRC bits. Software should disable CRC checks for those commands in order to disable CRC checking by controller. **Value** **Description** 0x0 Do not check response CRC 0x1 Check Response CRC	RW	0x0
7	response_length	Provides long and short response **Value** **Description** 0x0 Short response expected from card 0x1 Long response expected from card	RW	0x0
6	response_expect	Response expected from card. **Value** **Description** 0x0 No response expected from card 0x1 Response expected from card	RW	0x0

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				tx_wmark RW 0x0											

fifoth Fields

Bit	Name	Description	Access	Reset
30:28	dw_dma_multiple_transaction_size	Burst size of multiple transaction; should be programmed same as DMA controller multiple-transaction-size SRC/DEST_MSIZE. The units for transfers is 32 bits. A single transfer would be signalled based on this value. Value should be sub-multiple of 512. Allowed combinations for MSize and TX_WMark. **Value** — **Description** 0x0 — Msize 1 and TX_WMARK 1-1023 0x1 — Msize 4 and TX_WMARK 256 0x2 — Msize 8 and TX_WMARK 128 0x3 — Msize 16 and TX_WMARK 64 0x5 — Msize 1 and RX_WMARK 512 0x6 — Msize 4 and RX_WMARK 128 0x7 — Msize 8 and RX_WMARK 64	RW	0x0
27:16	rx_wmark	FIFO threshold watermark level when receiving data to card. When FIFO data count reaches greater than this number, DMA/FIFO request is raised. During end of packet, request is generated regardless of threshold programming in order to complete any remaining data. In non-DMA mode, when receiver FIFO threshold (RXDR) interrupt is enabled, then interrupt is generated instead of DMA request. During end of packet, interrupt is not generated if threshold programming is larger than any remaining data. It is responsibility of host to read remaining bytes on seeing Data Transfer Done interrupt. In DMA mode, at end of packet, even if remaining bytes are less than threshold, DMA request does single transfers to flush out any remaining bytes before Data Transfer Done interrupt is set. 12 bits - 1 bit less than FIFO-count of status register, which is 13 bits. Limitation: RX_WMark <= 1022 Recommended: 511; means greater than (FIFO_DEPTH/2) - 1) NOTE: In DMA mode during CCS time-out, the DMA does not generate the request at the end of packet, even if remaining bytes are less than threshold. In this case, there will be some data left in the FIFO. It is the responsibility of the application to reset the FIFO after the CCS timeout.	RW	0x3FF

Bit	Name	Description	Access	Reset
11:0	tx_wmark	FIFO threshold watermark level when transmitting data to card. When FIFO data count is less than or equal to this number, DMA/FIFO request is raised. If Interrupt is enabled, then interrupt occurs. During end of packet, request or interrupt is generated, regardless of threshold programming. In non-DMA mode, when transmit FIFO threshold (TXDR) interrupt is enabled, then interrupt is generated instead of DMA request. During end of packet, on last interrupt, host is responsible for filling FIFO with only required remaining bytes (not before FIFO is full or after CIU completes data transfers, because FIFO may not be empty). In DMA mode, at end of packet, if last transfer is less than burst size, DMA controller does single cycles until required bytes are transferred. 12 bits - 1 bit less than FIFO-count of status register, which is 13 bits. Limitation: TX_WMark >= 1; Recommended: FIFO_DEPTH/2 = 512; (means less than or equal to 512)	RW	0x0

Quad SPI Flash Controller 15

2014.12.15

av_5v4

The hard processor system (HPS) provides a quad serial peripheral interface (SPI) flash controller for access to serial NOR flash devices. The quad SPI flash controller supports standard SPI flash devices as well as high-performance dual and quad SPI flash devices. The quad SPI flash controller is based on Cadence Quad SPI Flash Controller (QSPI_FLASH_CTRL).

Features of the Quad SPI Flash Controller

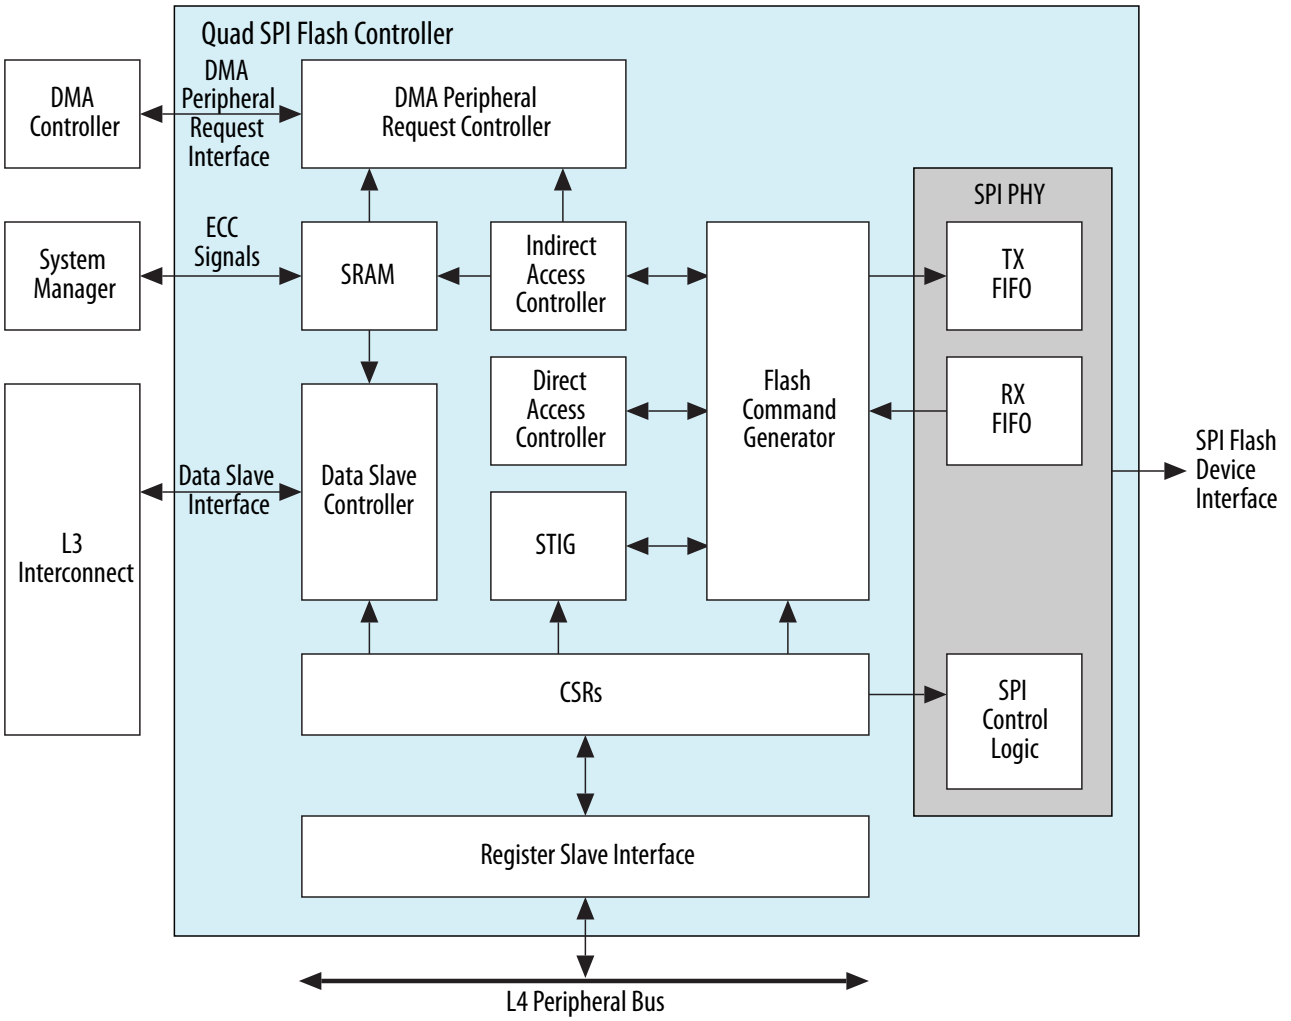
The quad SPI flash controller supports the following features:

- Single, dual, and quad I/O commands
- Device frequencies up to 108 MHz(*)
- Direct access and indirect access modes
- External direct memory access (DMA) controller support for indirect transfers
- Configurable clock polarity and phase
- Programmable write-protected regions
- Programmable delays between transactions
- Programmable device sizes
- Read data capture tuning
- Local buffering with error correction code (ECC) logic for indirect transfers
- Up to four devices
-
- Supports the Micron N25Q512A (512 MB, 108 MHz) and Micron N25Q00AA (1024 MB, 108 MHz) Quad SPI flash memories that have been verified to work properly with the HPS.
- eXecute-In-Place (XIP) mode

(*) The quad SPI controller supports any device frequencies, but this speed is limited by the supported flash devices.

Quad SPI Flash Controller Block Diagram and System Integration

Figure 15-1: Quad SPI Flash Controller Block Diagram and System Integration



The quad SPI controller consists of the following blocks and interfaces:

- Register slave interface—Slave interface that provides access to the control and status registers (CSRs)
- Data slave controller—Slave interface and controller that provides the following functionality:
  - Performs data transfers to and from the level 3 (L3) interconnect
  - Validates incoming accesses
  - Performs byte or half-word reordering
  - Performs write protection
  - Forwards transfer requests to direct and indirect controller
- Direct access controller—provides memory-mapped slaves direct access to the flash memory
- Indirect access controller—provides higher-performance access to the flash memory through local buffering and software transfer requests

- Software triggered instruction generator (STIG)—generates flash commands through the flash command register (`flashcmd`) and provides low-level access to flash memory
- Flash command generator—generates flash command and address instructions based on instructions from the direct and indirect access controllers or the STIG
- DMA peripheral request controller—issues requests to the DMA peripheral request interface to communicate with the external DMA controller
- SPI PHY—serially transfers data and commands to the external SPI flash devices

Functional Description of the Quad SPI Flash Controller

Overview

The quad SPI flash controller uses the register slave interface to select the operation modes and configure the data slave interface for data transfers. The quad SPI flash controller uses the data slave interface for direct and indirect accesses, and the register slave interface for software triggered instruction generator (STIG) operation and SPI legacy mode accesses.

Accesses to the data slave are forwarded to the direct or indirect access controller. If the access address is within the configured indirect address range, the access is sent to the indirect access controller.

Data Slave Interface

The quad SPI flash controller uses the data slave interface for direct, indirect, and SPI legacy mode accesses.

The data slave interface is 32 bits wide and permits byte, half-word, and word accesses. For write accesses, incrementing burst lengths of 1, 4, 8 and 16 are supported. For read accesses, all burst types and sizes are supported.

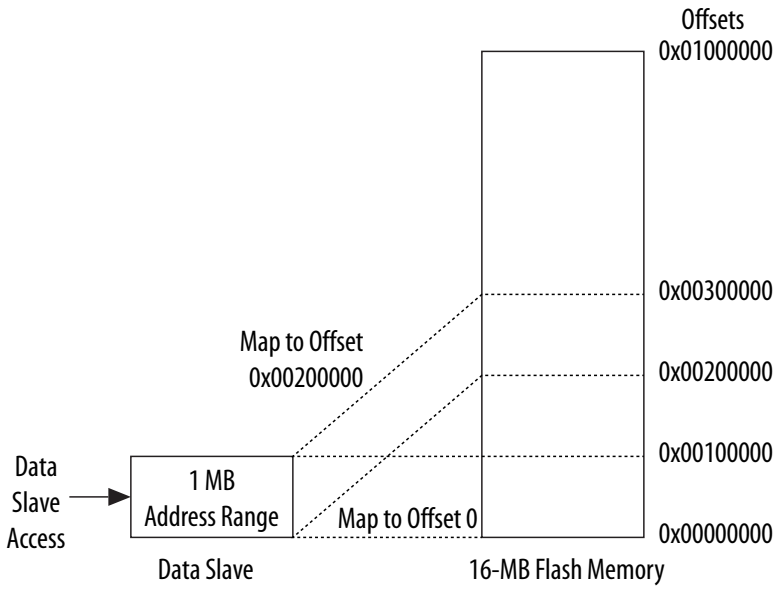
Direct Access Mode

Direct access mode is memory mapped and can be used to both access and directly execute code from external FLASH memory. Any incoming AMBA data slave interface access that is not recognized as being within the programmable indirect trigger region is assumed to be a direct access and is serviced by the direct access controller.

Note: Accesses that use the direct access controller do not use the embedded SRAM.

Data Slave Remapping Example

Figure 15-2: Data Slave Remapping Example



To remap the data slave to access other 1 MB regions of the flash device, enable address remapping in the enable ARM® AMBA® advanced high speed bus (AHB) address remapping field (`enahbremap`) of the `cfg` register. All incoming data slave accesses remap to the offset specified in the remap address register (`remapaddr`).

The 20 LSBs of incoming addresses are used for accessing the 1 MB region and the higher bits are ignored.

Note: The quad SPI controller does not issue any error status for accesses that lie outside the connected flash memory space.

AHB

The data slave interface is throttled as the read or write burst is carried out. The latency is designed to be as small as possible and is kept to a minimum when the use of XIP read instructions are enabled.

FLASH erase operations, which may be required before a page write, are triggered by software using the documented programming interface. They are not issued automatically.

Once a page program cycle has been started, the QSPI Flash Controller will automatically poll for the write cycle to complete before allowing any further data slave interface accesses to complete. This is achieved by holding any subsequent AHB direct accesses in wait state.

Indirect Access Mode

In indirect access mode, flash data is temporarily buffered in the quad SPI controller's static RAM (SRAM). Software controls and triggers indirect accesses through the register slave interface. The controller transfers data through the data slave interface.

Indirect Read Operation

An indirect read operation reads data from the flash memory, places the data into the SRAM, and transfers the data to an external master through the data slave interface. The indirect read operations are controlled by the following registers:

- Indirect read transfer register (`indrd`)
- Indirect read transfer watermark register (`indrdwater`)
- Indirect read transfer start address register (`indrdstaddr`)
- Indirect read transfer number bytes register (`indrdcnt`)
- Indirect address trigger register (`indaddrtrig`)

These registers need to be configured prior to issuing indirect read operations. The start address needs to be defined in the `indrdstaddr` register and the total number of bytes to be fetched is specified in the `indircnt` register. Writing 1 to the start indirect read bit (`start`) of the `indrd` register triggers the indirect read operation from the flash memory to populate the SRAM with the returned data.

To read data from the flash device into the SRAM, an external master issues 32-bit read transactions to the data slave interface. The address of the read access must be in the indirect address range. You can configure the indirect address through the `indaddrtrig` register. The external master can issue 32-bit reads until the last word of an indirect transfer. On the final read, the external master may issue a 32-bit, 16-bit or 8-bit read to complete the transfer. If there are less than four bytes of data to read on the last transfer, the external master can still issue a 32-bit read and the quad SPI controller will pad the upper bits of the response data with zeros.

Assuming the requested data is present in the SRAM at the time the data slave read is received by the quad SPI controller, the data is fetched from SRAM and the response to the read burst is achieved with minimum latency. If the requested data is not immediately present in the SRAM, the data slave interface enters a wait state until the data has been read from flash memory into SRAM. Once the data has been read from SRAM by the external master, the quad SPI controller frees up the associated resource in the SRAM. If the SRAM is full, reads on the SPI interface are backpressured until space is available in the SRAM. The quad SPI controller completes any current read burst, waits for SRAM to free up, and issues a new read burst at the address where the previous burst was terminated.

The processor can also use the SRAM fill level in the SRAM fill register (`sramfill`) to control when data should be fetched from the SRAM.

Another alternative is to use the fill level watermark of the SRAM, which you configure in the `indrdwater` register. When the SRAM fill level passes the watermark level, the indirect transfer watermark interrupt is generated. You can disable the watermark feature by writing zero to the `indrdwater` register.

For the final bytes of data read by the quad SPI controller and placed in the SRAM, if the watermark level is greater than zero, the indirect transfer watermark interrupt is generated even when the actual SRAM fill level has not risen above the watermark.

If the address of the read access is outside the range of the indirect trigger address, one of the following actions occurs:

- When direct access mode is enabled, the read uses direct access mode.
- When direct access mode is disabled, the slave returns an error back to the requesting master.

You can cancel an indirect operation by setting the cancel indirect read bit (`cancel`) of the `indrd` register to 1. For more information, refer to the *"Indirect Read Operation with DMA Disabled"* section.

Related Information

Indirect Read Operation with DMA Disabled on page 15-15

Indirect Write Operation

An indirect write operation programs data from the SRAM to the flash memory. The indirect write operations are controlled by the following registers:

- Indirect write transfer register (`indwr`)
- Indirect write transfer watermark register (`indwrwater`)
- Indirect write transfer start address register (`indwrstaddr`)
- Indirect write transfer number bytes register (`indwrcnt`)
- `indaddrtrig` register

These registers need to be configured prior to issuing indirect write operations. The start address needs to be defined in the `indwrstaddr` register and the total number of bytes to be written is specified in the `indwrcnt` register. The start indirect write bit (`start`) of the `indwr` register triggers the indirect write operation from the SRAM to the flash memory.

To write data from the SRAM to the flash device, an external master issues 32-bit write transactions to the data slave. The address of the write access must be in the indirect address range. You can configure the indirect address through the `indaddrtrig` register. The external master can issue 32-bit writes until the last word of an indirect transfer. On the final write, the external master may issue a 32-bit, 16-bit or 8-bit write to complete the transfer. If there are less than four bytes of data to write on the last transfer, the external master can still issue a 32-bit write and the quad SPI controller discards the extra bytes.

The SRAM size can limit the amount of data that the quad SPI controller can accept from the external master. If the SRAM is not full at the point of the write access, the data is pushed to the SRAM with minimum latency. If the external master attempts to push more data to the SRAM than the SRAM can accept, the quad SPI controller backpressures the external master with wait states. When the SRAM resource is freed up by pushing the data from SRAM to the flash memory, the SRAM is ready to receive more data from the external master. When the SRAM holds an equal or greater number of bytes than the size of a flash page, or when the SRAM holds all the remaining bytes of the current indirect transfer, the quad SPI controller initiates a write operation to the flash memory.

The processor can also use the SRAM fill level, in the `sramfill` register, to control when to write more data into the SRAM.

Alternatively, you can configure the fill level watermark of the SRAM in the `indwrwater` register. When the SRAM fill level falls below the watermark level, an indirect transfer watermark interrupt is generated to tell software to write the next page of data to SRAM. Because the quad SPI controller initiates non-end-of-data writes to the flash memory only when the SRAM contains a full flash page of data, you must set the watermark level to a value greater than one flash page to avoid the system stalling. You can disable the watermark feature by writing zero to the `indwrwater` register.

If the address of the write access is outside the range of the indirect trigger address, one of the following actions occurs:

- When direct access mode is enabled, the write uses direct access mode.
- When direct access mode is disabled, the slave returns an error back to the requesting master.

You can cancel an indirect operation by setting the cancel indirect write bit (`cancel`) of the `indwr` register to 1. For more information, refer to the *"Indirect Write Operation with DMA Disabled"* section.

Related Information

Indirect Write Operation with DMA Disabled on page 15-16

Consecutive Reads and Writes

It is possible to trigger two indirect operations at a time by triggering the `start` bit of the `indrd` or `indwr` register twice in short succession. The second operation can be triggered while the first operation is in

progress. For example, software may trigger an indirect read or write operation while an indirect write operation is in progress. The corresponding start and count registers must be configured properly before software triggers each transfer operation.

This approach allows for a short turnaround time between the completion of one indirect operation and the start of a second operation. Any attempt to queue more than two operations causes the indirect read reject interrupt to be generated.

SPI Legacy Mode

SPI legacy mode allows software to access the internal TX FIFO and RX FIFO buffers directly, thus bypassing the direct, indirect and STIG controllers. Software accesses the TX FIFO and RX FIFO buffers by writing any value to any address through the data slave while legacy mode is enabled. You can enable legacy mode with the legacy IP mode enable bit (`enlegacyip`) of the `cfg` register.

Legacy mode allows the user to issue any flash instruction to the flash device, but imposes a heavy software overhead in order to manage the fill levels of the FIFO buffers effectively. The legacy SPI mode is bidirectional in nature, with data continuously being transferred both directions while the chip select is enabled. If the driver only needs to read data from the flash device, dummy data must be written to ensure the chip select stays active, and vice versa for write transactions.

For example, to perform a basic read of four bytes to a flash device that has three address bytes, software must write a total of eight bytes to the TX FIFO buffer. The first byte would be the instruction opcode, the next three bytes are the address, and the final four bytes would be dummy data to ensure the chip select stays active while the read data is returned. Similarly, because eight bytes were written to the TX FIFO buffer, software should expect eight bytes to be returned in the RX FIFO buffer. The first four bytes of this would be discarded, leaving the final four bytes holding the data read from the device.

Because the TX FIFO and RX FIFO buffers are four bytes deep each, software must maintain the FIFO buffer levels to ensure the TX FIFO buffer does not underflow and the RX FIFO buffer does not overflow. Interrupts are provided to indicate when the fill levels pass the watermark levels, which are configurable through the TX threshold register (`txtresh`) and RX threshold register (`rxtresh`).

Register Slave Interface

The quad SPI flash controller uses the register slave interface to configure the quad SPI controller through the quad SPI configuration registers, and to access flash memory under software control, through the `flashcmd` register in the STIG.

STIG Operation

The Software Triggered Instruction Generator (STIG) is used to access the volatile and non-volatile configuration registers, the legacy SPI status register, and other status and protection registers. The STIG also is used to perform ERASE functions. The direct and indirect access controllers are used only to transfer data. The `flashcmd` register uses the following parameters to define the command to be issued to the flash device:

- Instruction opcode
- Number of address bytes
- Number of dummy bytes
- Number of write data bytes
- Write data
- Number of read data bytes

The address is specified through the flash command address register (`flashcmdaddr`). Once these settings have been specified, software can trigger the command with the execute command field (`execcmd`) of the

flashcmd register and wait for its completion by polling the command execution status bit (cmdexecstat) of the flashcmd register. A maximum of eight data bytes may be read from the flash command read data lower (flashcmdrddatalo) and flash command read data upper (flashcmdrddataup) registers or written to the flash command write data lower (flashcmdwrdatalo) and flash command write data upper (flashcmdwrdataup) registers per command.

Commands issued through the STIG have a higher priority than all other read accesses and therefore interrupt any read commands being requested by the direct or indirect controllers. However, the STIG does not interrupt a write sequence that may have been issued through the direct or indirect access controller. In these cases, it might take a long time for the cmdexecstat bit of the flashcmd register indicates the operation is complete.

Note: Altera recommends using the STIG instead of the SPI legacy mode to access the flash device registers and perform erase operations.

Local Memory Buffer

The SRAM local memory buffer is a 128 by 32-bit (512 total bytes) memory and includes support for error correction code (ECC). The ECC logic provides outputs to notify the system manager when single-bit correctable errors are detected (and corrected) and when double-bit uncorrectable errors are detected. The ECC logic also allows the injection of single- and double-bit errors for test purposes.

The SRAM has two partitions, with the lower partition reserved for indirect read operations and the upper partition for indirect write operations, as shown in **Figure 15-1**. The size of the partitions is specified in the SRAM partition register (srampart), based on 32-bit word sizes. For example, to specify four bytes of storage, write the value 1. The value written to the indirect read partition size field (addr) defines the number of entries reserved for indirect read operations. For example, write the value 32 (0x20) to partition the 128-entry SRAM to 32 entries (25%) for read usage and 96 entries (75%) for write usage.

For more information about ECC, refer to the *System Manager* chapter in volume 3 of the Arria® V Device Handbook.

System Manager on page 5-1

DMA Peripheral Request Controller

The DMA peripheral request controller is only used for the indirect mode of operation where data is temporarily stored in the SRAM. The quad SPI flash controller uses the DMA peripheral request interface to trigger the external DMA into performing data transfers between memory and the quad SPI controller.

There are two DMA peripheral request interfaces, one for indirect reads and one for indirect writes. The DMA peripheral request controller can issue two types of DMA requests, single or burst, to the external DMA. The number of bytes for each single or burst request is specified in the number of single bytes (numsglreqbytes) and number of burst bytes (numburstreqbytes) fields of the DMA peripheral register (dmaper). The DMA peripheral request controller splits the total amount of data to be transferred into a number of DMA burst and single requests by dividing the total number of bytes by the number of bytes specified in the burst request, and then dividing the remainder by the number of bytes in a single request.

Note: When programming the DMA controller, the burst request size must match the burst request size set in the quad SPI controller to avoid quickly reaching an overflow or underflow condition.

For indirect reads, the DMA peripheral request controller only issues DMA requests after the data has been retrieved from flash memory and written to SRAM. The rate at which DMA requests are issued depends on the watermark level. The indrdwater register defines the minimum fill level in bytes at which the DMA peripheral request controller can issue the DMA request. The higher this number is, the more

data that must be buffered in SRAM before the external DMA moves the data. When the SRAM fill level passes the watermark level, the transfer watermark reached interrupt is generated.

For example, consider the following conditions:

- The total amount of data to be read using indirect mode is 256 bytes
- The SRAM watermark level is set at 128 bytes
- Software configures the burst type transfer size to 64 bytes

Under these conditions, the DMA peripheral request controller issues the first DMA burst request when the SRAM fill level passes 128 bytes (the watermark level). The DMA peripheral request controller triggers consecutive DMA burst requests as long as there is sufficient data in the SRAM to perform burst type requests. In this example, DMA peripheral request controller can issue at least two consecutive DMA burst requests to transfer a total of 128 bytes. If there is sufficient data in the SRAM, the DMA peripheral request controller requests the third DMA burst immediately. Otherwise the DMA peripheral request controller waits for the SRAM fill level to pass the watermark level again to trigger the next burst request. When the watermark level is triggered, there is sufficient data in the SRAM to perform the third and fourth burst requests to complete the entire transaction.

For the indirect writes, the DMA peripheral request controller issues DMA requests immediately after the transfer is triggered and continues to do so until the entire indirect write transfer has been transferred. The rate at which DMA requests are issued depends on the watermark level. The `indwrwater` register defines the maximum fill level in bytes at which the controller can issue the first DMA burst or single request. When the SRAM fill level falls below the watermark level, the transfer watermark reached interrupt is generated. When there is one flash page of data in the SRAM, the quad SPI controller initiates the write operation from SRAM to the flash memory.

Software can disable the DMA peripheral request interface with the `endma` field of the `cfg` register. If a master other than the DMA performs the data transfer for indirect operations, the DMA peripheral request interface must be disabled. By default, the indirect watermark registers are set to zero, which means the DMA peripheral request controller can issue DMA request as soon as possible.

For more information about the HPS DMA controller, refer to the *DMA Controller* chapter in volume 3 of the Arria® V Device Handbook.

DMA Controller on page 16-1

Arbitration between Direct/Indirect Access Controller and STIG

When multiple controllers are active simultaneously, a fixed-priority arbitration scheme is used to arbitrate between each interface and access the external FLASH. The fixed priority is defined as follows, highest priority first.

1. The Indirect Access Write
2. The Direct Access Write
3. The STIG
4. The Direct Access Read
5. The Indirect Access Read

Each controller is back pressured while waiting to be serviced.

Configuring the Flash Device

For read and write accesses, software must initialize the device read instruction register (`devrd`) and the device write instruction register (`devwr`). These registers include fields to initialize the instruction opcodes that should be used as well as the instruction type, and whether the instruction uses single, dual or quad pins for address and data transfer. To ensure the quad SPI controller can operate from a reset state, the opcode registers reset to opcodes compatible with single I/O flash devices.

The quad SPI flash controller uses the instruction transfer width field (`instwidth`) of the `devrd` register to set the instruction transfer width for both reads and writes. There is no `instwidth` field in the `devwr` register. If instruction type is set to dual or quad mode, the address transfer width (`addrwidth`) and data transfer width (`datawidth`) fields of both registers are redundant because the address and data type is based on the instruction type. Thus, software can support the less common flash instructions where the opcode, address, and data are sent on two or four lanes. For most instructions, the opcodes are sent serially to the flash device, even for dual and quad instructions. One of the flash devices that supports instructions that can send the opcode over two or four lanes is the Micron N25Q128. For reference, **Table 15-1** and **Table 15-2** show how software should configure the quad SPI controller for each specific read and write instruction, respectively, supported by the Micron N25Q128 device.

Table 15-1: Quad SPI Configuration for Micron N25Q128 Device (Read Instructions)

Instruction	Lanes Used By Opcode	Lanes Used to Send Address	Lanes Used to Send Data	instwidth Value	addrwidth Value	datawidth Value
Read	1	1	1	0	0	0
Fast read	1	1	1	0	0	0
Dual output fast read (DOFR)	1	1	2	0	0	1
Dual I/O fast read (DIOFR)	1	2	2	0	1	1
Quad output fast read (QOFR)	1	1	4	0	0	2
Quad I/O fast read (QIOFR)	1	4	4	0	2	2
Dual command fast read (DCFR)	2	2	2	1	Don't care	Don't care
Quad command fast read (QCFR)	4	4	4	2	Don't care	Don't care

Table 15-2: Quad SPI Configuration for Micron N25Q128 Device (Write Instructions)

Instruction	Lanes Used By Opcode	Lanes Used to Send Address	Lanes Used to Send Data	instwidth Value	addrwidth Value	datawidth Value
Page program	1	1	1	0	0	0
Dual input fast program (DIFP)	1	1	2	0	0	1
Dual input extended fast program (DIEFP)	1	2	2	0	1	1

Dual command fast program (DCFP)	2	2	2	1	Don't care	Don't care
Quad command fast program (QCFP)	4	4	4	2	Don't care	Don't care

XIP Mode

The quad SPI controller supports XIP mode, if the flash devices support XIP mode. Depending on the flash device, XIP mode puts the flash device in read-only mode, reducing command overhead.

The quad SPI controller must instruct the flash device to enter XIP mode by sending the mode bits. When the enter XIP mode on next read bit (`enterxipnextrd`) of the `cfg` register is set to 1, the quad SPI controller and the flash device are ready to enter XIP mode on the next read instruction. When the enter XIP mode immediately bit (`enterxipimm`) of the `cfg` register is set to 1, the quad SPI controller and flash device enter XIP mode immediately.

When the `enterxipnextrd` or `enterxipimm` bit of the `cfg` register is set to 0, the quad SPI controller and flash device exit XIP mode on the next read instruction. For more information, refer to the *"XIP Mode Operations"* section.

Related Information

XIP Mode Operations on page 15-17

Write Protection

You can program the controller to write protect a specific region of the flash device. The protected region is defined as a set of blocks, specified by a starting and ending block. Writing to an area of protected flash region memory generates an error and triggers an interrupt.

You define the block size by specifying the number of bytes per block through the number of bytes per block field (`bytespersubsector`) of the device size register (`devsz`). The lower write protection register

(lowwrprot) specifies the first flash block in the protected region. The upper write protection register (uppwrprot) specifies the last flash block in the protected region.

The write protection enable bit (en) of the write protection register (wrprot) enables and disables write protection. The write protection inversion bit (inv) of the wrprot register flips the definition of protection so that the region specified by lowwrprt and uppwrprt is unprotected and all flash memory outside that region is protected.

Data Slave Sequential Access Detection

The quad SPI flash controller detects sequential accesses to the data slave interface by comparing the current access with the previous access. An access is sequential when it meets the following conditions:

- The address of the current access sequentially follows the address of the previous access.
- The direction of the current access (read or write) is the same as previous access.
- The size of the current access (byte, half-word, or word) is the same as previous access.

When the access is detected as nonsequential, the sequential access to the flash device is terminated and a new sequential access begins. Altera recommends accessing the data slave sequentially. Sequential access has less command overhead, and therefore, increases data throughput.

Clocks

There are two clock inputs to the quad SPI controller (l4_mp_clk and qspi_clk) and one clock output (sclk_out). The quad SPI flash controller uses the l4_mp_clk clock to clock the data slave transfers and register slave accesses. The qspi_clk clock is the reference clock for the quad SPI controller and is used to serialize the data and drive the external SPI interface. The sclk_out clock is the clock source for the connected flash devices.

The qspi_clk clock must be greater than two times the l4_mp_clk. The sclk_out clock is derived by dividing down the qspi_clk clock by the baud rate divisor field (bauddiv) of the cfg register.

Related Information

Clock Manager on page 2-1

Resets

A single reset signal (qspi_flash_rst_n) is provided as an input to the quad SPI controller. The Reset Manager drives the reset signal to the ECC controller on a cold or warm reset. This resets the logic inside the ECC controller.

Related Information

Reset Manager on page 3-1

Taking the Quad SPI Flash Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the MPU boots up, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

Interrupts

All interrupt sources are combined to create a single level-sensitive, active-high interrupt (qspi_intr). Software can determine the source of the interrupt by reading the interrupt status register (irqstat). By

default, the interrupt source is cleared when software writes a one (1) to the interrupt status register. The interrupts are individually maskable through the interrupt mask register (`irqmask`). **Table 15-3** lists the interrupt sources in the `irqstat` register.

Table 15-3: Interrupt Sources in the irqstat Register

Interrupt Source	Description
Underflow detected	When 0, no underflow has been detected. When 1, the data slave write data is being supplied too slowly. This situation can occur when data slave write data is being supplied too slowly to keep up with the requested write operation This bit is reset only by a system reset and cleared only when a 1 is written to it.
Indirect operation complete	The controller has completed a triggered indirect operation.
Indirect read reject	An indirect operation was requested but could not be accepted because two indirect operations are already in the queue.
Protected area write attempt	A write to a protected area was attempted and rejected.
Illegal data slave access detected	An illegal data slave access has been detected. Data slave wrapping bursts and the use of split and retry accesses can cause this interrupt. It is usually an indicator that soft masters in the FPGA fabric are attempting to access the HPS in an unsupported way.
Transfer watermark reached	The indirect transfer watermark level has been reached.
Receive overflow	This condition occurs only in legacy SPI mode. When 0, no overflow has been detected. When 1, an over flow to the RX FIFO buffer has occurred. This bit is reset only by a system reset and cleared to zero only when this register is written to. If a new write to the RX FIFO buffer occurs at the same time as a register is read, this flag remains set to 1.
TX FIFO not full	This condition occurs only in legacy SPI mode. When 0, the TX FIFO buffer is full. When 1, the TX FIFO buffer is not full.
TX FIFO full	This condition occurs only in legacy SPI mode. When 0, the TX FIFO buffer is not full. When 1, the TX FIFO buffer is full.

Interrupt Source	Description
RX FIFO not empty	This condition occurs only in legacy SPI mode. When 0, the RX FIFO buffer is empty. When 1, the RX FIFO buffer is not empty.
RX FIFO full	This condition occurs only in legacy SPI mode. When 0, the RX FIFO buffer is not full. When 1, the RX FIFO buffer is full.
Indirect read partition overflow	Indirect Read Partition of SRAM is full and unable to immediately complete indirect operation

Interface Signals

The quad SPI controller provides four chip select outputs to allow control of up to four external quad SPI flash devices. The outputs serve different purposes depending on whether the device is used in single, dual, or quad operation mode. The following table lists the I/O pin use of the quad SPI controller interface signals for each operation mode.

Table 15-4: Interface Signals

Signal	Mode	Direction	Function
`data[0]`	Single	Output	Data output 0
	Dual or quad	Bidirectional	Data I/O 0
`data[1]`	Single	Input	Data input 0
	Dual or quad	Bidirectional	Data I/O 1
`data[2]`	Single or dual	Output	Active low write protect
	Quad	Bidirectional	Data I/O 2
`data[3]`	Single, dual, or quad	Bidirectional	Data I/O 3
`ss_n[0]`	Single, dual, or quad	Output	Active low slave select 0
`ss_n[1]`			Active low slave select 1
`ss_n[2]`			Active low slave select 2
`ss_n[3]`			Active low slave select 3
`sclk`	Single, dual, or quad	Output	Serial Clock

Quad SPI Flash Controller Programming Model

Setting Up the Quad SPI Flash Controller

The following steps describe how to set up the quad SPI controller:

1. Wait until any pending operation has completed.
2. Disable the quad SPI controller with the quad SPI enable field (`en`) of the `cfg` register.
3. Update the `instwidth` field of the `devrd` register with the instruction type you wish to use for indirect and direct writes and reads.
4. If mode bit enable bit (`enmodebits`) of the `devrd` register is enabled, update the mode bit register (`modebit`).
5. Update the `devsz` register as needed. Parts or all of this register might have been updated after initialization. The number of address bytes is a key configuration setting required for performing reads and writes. The number of bytes per page is required for performing any write. The number of bytes per device block is only required if the write protect feature is used.
6. Update the device delay register (`delay`). This register allows the user to adjust how the chip select is driven after each flash access. Each device may have different timing requirements. If the serial clock frequency is increased, these timing requirements become more critical. The numbers specified in this register are based on the period of the `qspi_clk` clock. For example, an some devices need 50 ns minimum time before the slave select can be reasserted after it has been deasserted. When the device is operating at 100 MHz, the clock period is 10 ns, so 40 ns extra is required. If the `qspi_clk` clock is running at 400 MHz (2.5 ns period), specify a value of at least 16 to the clock delay for chip select deassert field (`nss`) of the `delay` register.
7. Update the `remapaddr` register as needed. This register only affects direct access mode.
8. Set up and enable the write protection registers (`wrprot`, `lowwrprot`, and `uppwrprot`), when write protection is required.
9. Enable required interrupts though the `irqmask` register.
10. Set up the `bauddiv` field of the `cfg` register to define the required clock frequency of the target device.
11. Update the read data capture register (`rddatacap`) as needed. This register delays when the read data is captured and can help when the read data path from the device to the quad SPI controller is long and the device clock frequency is high.
12. Enable the quad SPI controller with the `en` field of the `cfg` register.

Indirect Read Operation with DMA Disabled

The following steps describe the general software flow to set up the quad SPI controller for indirect read operation with the DMA disabled:

1. Perform the steps described in the **Setting Up the Quad SPI Flash Controller** on page 15-15 section.
2. Set the flash memory start address in the `indrdstaddr` register.
3. Set the number of bytes to be transferred in the `indrdcnt` register.
4. Set the indirect transfer trigger address in the `indaddrtrig` register.
5. Set up the required interrupts through the `irqmask` register.
6. If the watermark level is used, set the SRAM watermark level through the `indrdwater` register.
7. Start the indirect read operation by setting the `start` field of the `indrd` register to 1.

8. Either use the watermark level interrupt or poll the SRAM fill level in the `sramfill` register to determine when there is sufficient data in the SRAM.
9. Issue a read transaction to the indirect address to access the SRAM. Repeat **step 8** if more read transactions are needed to complete the indirect read transfer.
10. Either use the indirect complete interrupt to determine when the indirect read operation has completed or poll the completion status of the indirect read operation through the indirect completion status bit (`ind_ops_done_status`) of the `indrd` register.

Related Information

Setting Up the Quad SPI Flash Controller on page 15-15

Indirect Read Operation with DMA Enabled

The following steps describe the general software flow to set up the quad SPI controller for indirect read operation with the DMA enabled:

1. Perform the steps described in the **Setting Up the Quad SPI Flash Controller** on page 15-15 section.
2. Set the flash memory start address in the `indrdstaddr` register.
3. Set the number of bytes to be transferred in the `indrdcnt` register.
4. Set the indirect transfer trigger address in the `indaddrtrig` register.
5. Set the number of bytes for single and burst type DMA transfers in the `dmaper` register.
6. Optionally set the SRAM watermark level in the `indrdwater` register to control the rate DMA requests are issued.
7. Start an indirect read access by setting the `start` field of the `indrd` register to 1.
8. Either use the indirect complete interrupt to determine when the indirect read operation has completed or poll the completion status of the indirect read operation through the `ind_ops_done_status` field of the `indrd` register.

Related Information

Indirect Write Operation with DMA Disabled

The following steps describe the general software flow to set up the quad SPI controller for indirect write operation with the DMA disabled:

1. Perform the steps described in the **Setting Up the Quad SPI Flash Controller** on page 15-15 section.
2. Set the flash memory start address in the `indwrstaddr` register.
3. Set up the number of bytes to be transferred in the `indwrcnt` register.
4. Set the indirect transfer trigger address in the `indaddrtrig` register.
5. Set up the required interrupts through the interrupt mask register (`irqmask`).
6. Optionally set the SRAM watermark level in the `indwrwater` register to control the rate DMA requests are issued. The value set must be greater than one flash page. For more information, refer to the **Indirect Write Operation** on page 15-6 section.

7. Start the indirect write operation by setting the `start` field of the `indwr` register to 1.
8. Either use the watermark level interrupt or poll the SRAM fill level in the `sramfill` register to determine when there is sufficient space in the SRAM.
9. Issue a write transaction to the indirect address to write one flash page of data to the SRAM. Repeat **step 8** if more write transactions are needed to complete the indirect write transfer. The final write may be less than one page of data.

XIP Mode Operations

XIP mode is supported in most SPI flash devices. However, flash device manufacturers do not use a consistent standard approach. Most use signature bits that are sent to the device immediately following the address bytes. Some devices use signature bits and also require a flash device configuration register write to enable XIP mode.

Entering XIP Mode

Micron Quad SPI Flash Devices with Support for Basic-XIP

To enter XIP mode in a Micron quad SPI flash device with support for Basic-XIP, perform the following steps:

1. Save the values in the mode bits, if you intend to restore them upon exit.
2. Disable the direct access controller and indirect access controller to ensure no new read or write accesses are sent to the flash device.
3. Set the XIP mode bits in the `modebit` register to 0x80.
4. Enable the quad SPI controller's XIP mode by setting the `enterxipnextrd` bit of the `cfg` register to 1.
5. Re-enable the direct access controller and, if required, the indirect access controller.

Micron Quad SPI Flash Devices without Support for Basic-XIP

To enter XIP mode in a Micron quad SPI flash device without support for Basic-XIP, perform the following steps:

1. Save the values in the mode bits, if you intend to restore them upon exit.
2. Disable the direct access controller and indirect access controller to ensure no new read or write accesses will be sent to the flash device.
3. Ensure XIP mode is enabled in the flash device by setting the volatile configuration register (VCR) bit 3 to 1. Use the `flashcmd` register to issue the VCR write command.
4. Set the XIP mode bits in the `modebit` register to 0x00.
5. Enable the quad SPI controller's XIP mode by setting the `enterxipnextrd` bit of the `cfg` register to 1.
6. Re-enable the direct access controller and, if required, the indirect access controller.

Winbond Quad SPI Flash Devices

To enter XIP mode in a Winbond quad SPI flash device, perform the following steps:

1. Save the values in the mode bits, if you intend to restore them upon exit.
2. Disable the direct access controller and indirect access controller to ensure no new read or write accesses are sent to the flash device.
3. Set the XIP mode bits in the `modebit` register to 0x20.
4. Enable the quad SPI controller's XIP mode by setting the `enterxipnextrd` bit of the `cfg` register to 1.
5. Re-enable the direct access controller and, if required, the indirect access controller.

Spansion Quad SPI Flash Devices

To enter XIP mode a Spansion quad SPI flash device, perform the following steps:

1. Save the values in the mode bits, if you intend to restore them upon exit.
2. Disable the direct access controller and indirect access controller to ensure no new read or write accesses are sent to the flash device.
3. Set the XIP mode bits in the `modebit` register to 0xA0.
4. Enable the quad SPI controller's XIP mode by setting the `enterxipnextrd` bit of the `cfg` register to 1.
5. Re-enable the direct access controller and, if required, the indirect access controller.

Exiting XIP Mode

To exit XIP mode, perform the following steps:

1. Disable the direct access controller and indirect access controller to ensure no new read or write accesses are sent to the flash device.
2. Restore the mode bits to the values before entering XIP mode, depending on the flash device and manufacturer.
3. Set the `enterxipnextrd` bit of the `cfg` register to 0.

The flash device must receive a read instruction before it can disable its internal XIP mode state. Thus, XIP mode internally stays active until the next read instruction is serviced. Ensure that XIP mode is disabled before the end of any read sequence.

XIP Mode at Power on Reset

Some flash devices can be XIP-enabled as a nonvolatile configuration setting, allowing the flash device to enter XIP mode at power-on reset (POR) without software intervention. Software cannot discover the XIP state at POR through flash status register reads because an XIP-enabled flash device can only be accessed through the XIP read operation. If you known the device will enter XIP mode at POR, have your initial boot software configure the `modebit` register and set the `enterxipimm` bit of the `cfg` register to 1.

If you do not know in advance whether or not the device will enter XIP mode at POR, have your initial boot software issue an XIP mode exit command through the `flashcmd` register, then follow the steps in the *"Entering XIP Mode"* section. Software must be aware of the mode bit requirements of the device, because XIP mode entry and exit varies by device.

cfg Fields

Bit	Name	Description	Access	Reset
31	idle	This is a STATUS read-only bit. Note this is a retimed signal, so there will be some inherent delay on the generation of this status signal. **Value** **Description** 0x1 Idle Mode 0x0 Non-Idle Mode	RO	0x0

Bit	Name	Description	Access	Reset
22:19	bauddiv	SPI baud rate = ref_clk / (2 * baud_rate_divisor) **Value** — **Description** 0x0 — Baud Rate Div/2 0x1 — Baud Rate Div/4 0x2 — Baud Rate Div/6 0x3 — Baud Rate Div/8 0x4 — Baud Rate Div/10 0x5 — Baud Rate Div/12 0x6 — Baud Rate Div/14 0x7 — Baud Rate Div/16 0x8 — Baud Rate Div/18 0x9 — Baud Rate Div/20 0xa — Baud Rate Div/22 0xb — Baud Rate Div/24 0xc — Baud Rate Div/26 0xd — Baud Rate Div/28 0xe — Baud Rate Div/30 0xf — Baud Rate Div/32	RW	0xF
18	enterxipimm	If XIP is enabled, then setting to disabled will cause the controller to exit XIP mode on the next READ instruction. If XIP is disabled, then setting enable will operate the device in XIP mode immediately. Use this register when the external device wakes up in XIP mode (as per the contents of its non- volatile configuration register). The controller will assume the next READ instruction will be passed to the device as an XIP instruction, and therefore will not require the READ opcode to be transferred. Note: To exit XIP mode, this bit should be set to 0. This will take effect in the attached device only after the next READ instruction is executed. Software therefore should ensure that at least one READ instruction is requested after resetting this bit in order to be sure that XIP mode is exited. **Value** — **Description** 0x1 — Enter XIP Mode immediately 0x0 — Exit XIP Mode on next READ instruction	RW	0x0

Bit	Name	Description	Access	Reset
17	enterxipnextrd	If XIP is enabled, then setting to disabled will cause the controller to exit XIP mode on the next READ instruction. If XIP is disabled, then setting to enabled will inform the controller that the device is ready to enter XIP on the next READ instruction. The controller will therefore send the appropriate command sequence, including mode bits to cause the device to enter XIP mode. Use this register after the controller has ensured the FLASH device has been configured to be ready to enter XIP mode. Note : To exit XIP mode, this bit should be set to 0. This will take effect in the attached device only AFTER the next READ instruction is executed. Software should therefore ensure that at least one READ instruction is requested after resetting this bit before it can be sure XIP mode in the device is exited. **Value** **Description** 0x1 Enter XIP Mode on next READ instruction 0x0 Exit XIP Mode on next READ instruction	RW	0x0
16	enahbremap	(Direct Access Mode Only) When enabled, the incoming AHB address will be adapted and sent to the FLASH device as (address + N), where N is the value stored in the remap address register. **Value** **Description** 0x1 Enable AHB Re-mapping 0x0 Disable AHB Re-mapping	RW	0x0
15	endma	Allows DMA handshaking mode. When enabled the QSPI will trigger DMA transfer requests via the DMA peripheral interface. **Value** **Description** 0x1 Enable DMA Mode 0x0 Disable DMA Mode	RW	0x0

Bit	Name	Description	Access	Reset
14	wp	This bit controls the write protect pin of the flash devices. The signal qspi_mo2_wpn needs to be resynchronized to the generated memory clock as necessary. **Value** **Description** 0x1 Enable Write Protect 0x0 Disable Write Protect	RW	0x0
13:10	percslines	Peripheral chip select line output decode type. As per perseldec, if perseldec = 0, the decode is select 1 of 4 decoding on signals, qspi_n_ss_out[3:0], The asserted decode line goes to 0. If perseldec = 1, the signals qspi_n_ss_out[3:0] require an external 4 to 16 decoder.	RW	0x0
9	perseldec	Select between '1 of 4 selects' or 'external 4-to-16 decode'. The qspi_n_ss_out[3:0] output signals are controlled. **Value** **Description** 0x1 Select external 4-to-16 decode 0x0 Selects 1 of 4 qspi_n_ss_out[3:0]	RW	0x0
8	enlegacyip	This bit can select the Direct Access Controller/ Indirect Access Controller or legacy mode.If legacy mode is selected, any write to the controller via the AHB interface is serialized and sent to the FLASH device. Any valid AHB read will pop the internal RX-FIFO, retrieving data that was forwarded by the external FLASH device on the SPI lines, byte transfers of 4, 2 or 1 are permitted and controlled via the HSIZE input. **Value** **Description** 0x1 Legacy Mode 0x0 Use Direct/Indirect Access Controller	RW	0x0

Bit	Name	Description	Access	Reset
7	endiracc	If disabled, the Direct Access Controller becomes inactive once the current transfer of the data word (FF_W) is complete. When the Direct Access Controller and Indirect Access Controller are both disabled, all AHB requests are completed with an error response. **Value** **Description** 0x0 Disable Direct Access Ctrl 0x1 Enable Direct Access Ctrl	RW	0x0
2	selclkphase	Selects whether the clock is in an active or inactive phase outside the SPI word. **Value** **Description** 0x0 SPI clock is quiescent low 0x1 Clock Inactive	RW	0x0
1	selclkpol	Controls spiclk modes of operation. **Value** **Description** 0x1 SPI clock is quiescent low 0x0 SPI clock is quiescent high	RW	0x0
0	en	If this bit is disabled, the QSPI will finish the current transfer of the data word (FF_W) and stop sending. When Enabled, and qspi_n_mo_en = 0, all output enables are inactive and all pins are set to input mode. **Value** **Description** 0x0 Disable the QSPI 0x1 Enable the QSPI	RW	0x0

devrd

Module Instance	Base Address	Register Address

devrd Fields

Bit	Name	Description	Access	Reset
28:24	dummyrdclks	Number of dummy clock cycles required by device for read instruction.	RW	0x0
20	enmodebits	If this bit is set, the mode bits as defined in the Mode Bit Configuration register are sent following the address bytes. **Value** **Description** 0x0 No Order 0x1 Mode Bits follow address bytes	RW	0x0
17:16	datawidth	Sets read data transfer width (1, 2, or 4 bits). **Value** **Description** 0x0 Read data transferred on DQ0. Supported by all SPI flash devices 0x1 Read data transferred on DQ0 and DQ1. Supported by some SPI flash devices that support the Extended SPI Protocol and by all SPI flash devices that support the Dual SP (DIO-SPI) Protocol. 0x2 Read data transferred on DQ0, DQ1, DQ2, and DQ3. Supported by some SPI flash devices that support the Extended SPI Protocol and by all SPI flash devices that support the Quad SP (QIO-SPI) Protocol.	RW	0x0

Bit	Name	Description	Access	Reset
13:12	addrwidth	Sets read address transfer width (1, 2, or 4 bits). **Value** **Description** 0x0 Read address transferred on DQ0. Supported by all SPI flash devices 0x1 Read address transferred on DQ0 and DQ1. Supported by some SPI flash devices that support the Extended SPI Protocol and by all SPI flash devices that support the Dual SP (DIO-SPI) Protocol. 0x2 Read address transferred on DQ0, DQ1, DQ2, and DQ3. Supported by some SPI flash devices that support the Extended SPI Protocol and by all SPI flash devices that support the Quad SP (QIO-SPI) Protocol.	RW	0x0
9:8	instwidth	Sets instruction transfer width (1, 2, or 4 bits). Applies to all instructions sent to SPI flash device (not just read instructions). **Value** **Description** 0x0 Instruction transferred on DQ0. Supported by all SPI flash devices. 0x1 Instruction transferred on DQ0 and DQ1. Supported by all SPI flash devices that support the Dual SP (DIO-SPI) Protocol. 0x2 Instruction transferred on DQ0, DQ1, DQ2, and DQ3. Supported by all SPI flash devices that support the Quad SP (QIO-SPI) Protocol.	RW	0x0
7:0	rdopcode	Read Opcode to use when not in XIP mode **Value** **Description** 0x3 Read Opcode in Non-XIP mode 0xb Fast Read in Non-XIP mode	RW	0x3

devwr

devwr Fields

Bit	Name	Description	Access	Reset
28:24	dummywrclks	Number of dummy clock cycles required by device for write instruction.	RW	0x0
17:16	datawidth	Sets write data transfer width (1, 2, or 4 bits). **Value** — **Description** 0x0 — Write data transferred on DQ0. Supported by all SPI flash devices 0x1 — Read data transferred on DQ0 and DQ1. Supported by some SPI flash devices that support the Extended SPI Protocol and by all SPI flash devices that support the Dual SP (DIO-SPI) Protocol. 0x2 — Read data transferred on DQ0, DQ1, DQ2, and DQ3. Supported by some SPI flash devices that support the Extended SPI Protocol and by all SPI flash devices that support the Quad SP (QIO-SPI) Protocol.	RW	0x0

Bit	Name	Description	Access	Reset
13:12	addrwidth	Sets write address transfer width (1, 2, or 4 bits). **Value** — **Description** 0x0 — Write address transferred on DQ0. Supported by all SPI flash devices 0x1 — Read address transferred on DQ0 and DQ1. Supported by some SPI flash devices that support the Extended SPI Protocol and by all SPI flash devices that support the Dual SP (DIO-SPI) Protocol. 0x2 — Read address transferred on DQ0, DQ1, DQ2, and DQ3. Supported by some SPI flash devices that support the Extended SPI Protocol and by all SPI flash devices that support the Quad SP (QIO-SPI) Protocol.	RW	0x0
7:0	wropcode	Write Opcode	RW	0x2

delay

This register is used to introduce relative delays into the generation of the master output signals. All timings are defined in cycles of the qspi_clk.

Module Instance	Base Address	Register Address
qspiregs	0xFF705000	0xFF70500C

Offset: 0xC

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
nss RW 0x0								btwn RW 0x0							
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
after RW 0x0								init RW 0x0							

delay Fields

Bit	Name	Description	Access	Reset
31:24	nss	Delay in master reference clocks for the length that the master mode chip select outputs are de-asserted between transactions. The minimum delay is always qspi_sck_out period to ensure the chip select is never re-asserted within an qspi_sck_out period.	RW	0x0

Bit	Name	Description	Access	Reset
23:16	btwn	Delay in master reference clocks between one chip select being de-activated and the activation of another. This is used to ensure a quiet period between the selection of two different slaves and requires the transmit FIFO to be empty.	RW	0x0
15:8	after	Delay in master reference clocks between last bit of current transaction and deasserting the device chip select (qspi_n_ss_out). By default, the chip select will be deasserted on the cycle following the completion of the current transaction.	RW	0x0
7:0	init	Delay in master reference clocks between setting qspi_n_ss_out low and first bit transfer.	RW	0x0

rddatacap

Module Instance	Base Address	Register Address
qspiregs	0xFF705000	0xFF705010

Offset: 0x10

Reserved											delay RW 0x0				byp RW 0x1

rddatacap Fields

Bit	Name	Description	Access	Reset
4:1	delay	Delay the read data capturing logic by the programmed number of qspi_clk cycles	RW	0x0
0	byp	Controls bypass of the adapted loopback clock circuit **Value** **Description** 0x0 No Bypass 0x1 Bypass loopback clock circuit	RW	0x1

devsz

Module Instance	Base Address	Register Address
qspiregs	0xFF705000	0xFF705014

Offset: 0x14

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved											bytespersubsector RW 0x10				
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
bytesperdevicepage RW 0x100												numaddrbytes RW 0x2			

devsz Fields

Bit	Name	Description	Access	Reset
20:16	bytespersubsector	Number of bytes per Block. This is required by the controller for performing the write protection logic. The number of bytes per block must be a power of 2 number.	RW	0x10
15:4	bytesperdevicepage	Number of bytes per device page. This is required by the controller for performing FLASH writes up to and across page boundaries.	RW	0x100
3:0	numaddrbytes	Number of address bytes. A value of 0 indicates 1 byte.	RW	0x2

srampart

Module Instance	Base Address	Register Address
qspiregs	0xFF705000	0xFF705018

Offset: 0x18

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved									addr RW 0x40						

srampart Fields

Bit	Name	Description	Access	Reset
6:0	addr	Defines the size of the indirect read partition in the SRAM, in units of SRAM locations. By default, half of the SRAM is reserved for indirect read operations and half for indirect write operations.	RW	0x40

indaddrtrig

Module Instance	Base Address	Register Address
qspiregs	0xFF705000	0xFF70501C

Offset: 0x1C

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
addr RW 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
addr RW 0x0															

indaddrtrig Fields

Bit	Name	Description	Access	Reset
31:0	addr	This is the base address that will be used by the AHB controller. When the incoming AHB read access address matches a range of addresses from this trigger address to the trigger address + 15, then the AHB request will be completed by fetching data from the Indirect Controllers SRAM.	RW	0x0

dmaper

Module Instance	Base Address	Register Address
qspiregs	0xFF705000	0xFF705020

Offset: 0x20

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved				numburstreqbytes RW 0x0				Reserved				numsglreqbytes RW 0x0			

dmaper Fields

Bit	Name	Description	Access	Reset
11:8	numburstreqbytes	Number of bytes in a burst type request on the DMA peripheral request. A programmed value of 0 represents a single byte. This should be setup before starting the indirect read or write operation. The actual number of bytes used is 2**(value in this register) which will simplify implementation.	RW	0x0
3:0	numsglreqbytes	Number of bytes in a single type request on the DMA peripheral request. A programmed value of 0 represents a single byte. This should be setup before starting the indirect read or write operation. The actual number of bytes used is 2**(value in this register) which will simplify implementation.	RW	0x0

remapaddr

This register is used to remap an incoming AHB address to a different address used by the FLASH device.

Module Instance	Base Address	Register Address
qspiregs	0xFF705000	0xFF705024

Offset: 0x24

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
value RW 0x0

Reserved												level RW 0x1			

rxthresh Fields

Bit	Name	Description	Access	Reset
3:0	level	Defines the level at which the receive FIFO not empty interrupt is generated	RW	0x1

irqstat

The status fields in this register are set when the described event occurs and the interrupt is enabled in the mask register. When any of these bit fields are set, the interrupt output is asserted high. The fields are each cleared by writing a 1 to the field. Note that bit fields 7 thru 11 are only valid when legacy SPI mode is active.

irqstat Fields

Bit	Name	Description	Access	Reset
12	indsramfull	Indirect Read Partition of SRAM is full and unable to immediately complete indirect operation **Value** **Description** 0x1 SRAM is full 0x0 SRAM is not full	RW	0x0
11	rxfull	Indicates that the receive FIFO is full or not. Only relevant in SPI legacy mode. **Value** **Description** 0x0 Receive FIFO Not Full 0x1 Receive FIFO Full	RW	0x0
10	rxthreshcmp	Indicates the number of entries in the receive FIFO with respect to the threshold specified in the RXTHRESH register. Only relevant in SPI legacy mode. **Value** **Description** 0x0 FIFO has <= RXTHRESH entries 0x1 FIFO has > RXTHRESH entries	RW	0x0
9	txfull	Indicates that the transmit FIFO is full or not. Only relevant in SPI legacy mode. **Value** **Description** 0x0 Transmit FIFO Not Full 0x1 Transmit FIFO Full	RW	0x0
8	txthreshcmp	Indicates the number of entries in the transmit FIFO with respect to the threshold specified in the TXTHRESH register. Only relevant in SPI legacy mode. **Value** **Description** 0x0 FIFO has > TXTHRESH entries 0x1 FIFO has <= TXTHRESH entries	RW	0x1

Bit	Name	Description	Access	Reset
7	rxover	This should only occur in Legacy SPI mode. Set if an attempt is made to push the RX FIFO when it is full. This bit is reset only by a system reset and cleared only when this register is read. If a new push to the RX FIFO occurs coincident with a register read this flag will remain set. 0 : no overflow has been detected. 1 : an overflow has occurred. **Value** **Description** 0x1 Receive Overflow 0x0 No Receive Overflow	RW	0x0
6	indxfrlvl	Indirect Transfer Watermark Level Reached **Value** **Description** 0x1 Water level reached 0x0 No water level reached	RW	0x0
5	illegalacc	Illegal AHB access has been detected. AHB wrapping bursts and the use of SPLIT/RETRY accesses will cause this error interrupt to trigger. **Value** **Description** 0x1 Illegal AHB attempt 0x0 No Illegal AHB attempt	RW	0x0
4	protwrattempt	Write to protected area was attempted and rejected. **Value** **Description** 0x1 Write Attempt to protected area 0x0 No Write Attempt	RW	0x0
3	indrdreject	Indirect operation was requested but could not be accepted. Two indirect operations already in storage. **Value** **Description** 0x1 Indirect Operation Requested 0x0 No Indirect Operation	RW	0x0

Bit	Name	Description	Access	Reset
2	indopdone	Controller has completed last triggered indirect operation Value: 0x1 — Completed Indirect Operation Value: 0x0 — No Indirect Operation	RW	0x0
1	underflowdet	An underflow is detected when an attempt to transfer data is made when the transmit FIFO is empty. This may occur when the AHB write data is being supplied too slowly to keep up with the requested write operation. This bit is reset only by a system reset and cleared only when the register is read. Value: 0x1 — Underflow Value: 0x0 — No Underflow	RW	0x0

irqmask

If disabled, the interrupt for the corresponding interrupt status register bit is disabled. If enabled, the interrupt for the corresponding interrupt status register bit is enabled.

flashcmd Fields

Bit	Name	Description	Access	Reset
31:24	cmdopcode	The command opcode field should be setup before triggering the command. For example, 0x20 maps to SubSector Erase. Writeing to the execute field (bit 0) of this register launches the command. NOTE : Using this approach to issue commands to the device will make use of the instruction type of the device instruction configuration register. If this field is set to 2'b00, then the command opcode, command address, command dummy bytes and command data will all be transferred in a serial fashion. If this field is set to 2'b01, then the command opcode, command address, command dummy bytes and command data will all be transferred in parallel using DQ0 and DQ1 pins. If this field is set to 2'b10, then the command opcode, command address, command dummy bytes and command data will all be transferred in parallel using DQ0, DQ1, DQ2 and DQ3 pins.	RW	0x0
23	enrddata	If enabled, the command specified in the command opcode field (bits 31:24) requires read data bytes to be received from the device. **Value** — **Description** 0x1 — Command Requires read data 0x0 — No Action	RW	0x0
22:20	numrddatabytes	Up to 8 data bytes may be read using this command. Set to 0 for 1 byte and 7 for 8 bytes. **Value** — **Description** 0x0 — Read 1 Byte 0x1 — Read 2 Byte 0x2 — Read 3 Byte 0x3 — Read 4 Byte 0x4 — Read 5 Byte 0x5 — Read 6 Byte 0x6 — Read 7 Byte 0x7 — Read 8 Byte	RW	0x0

Bit	Name	Description	Access	Reset
19	encmdaddr	If enabled, the command specified in bits 31:24 requires an address. This should be setup before triggering the command via writing a 1 to the execute field. **Value** **Description** 0x1 Command in bits 31:24 requires address 0x0 No Action	RW	0x0
18	enmodebit	Set to 1 to ensure the mode bits as defined in the Mode Bit Configuration register are sent following the address bytes. **Value** **Description** 0x1 Mode Bit follows address bytes 0x0 No Action	RW	0x0
17:16	numaddrbytes	Set to the number of address bytes required (the address itself is programmed in the FLASH COMMAND ADDRESS REGISTERS). This should be setup before triggering the command via bit 0 of this register. 2'b00 : 1 address byte 2'b01 : 2 address bytes 2'b10 : 3 address bytes 2'b11 : 4 address bytes **Value** **Description** 0x0 Write 1 Address Byte 0x1 Write 2 Address Bytes 0x2 Write 3 Address Bytes 0x3 Write 4 Address Bytes	RW	0x0
15	enwrdata	Set to 1 if the command specified in the command opcode field requires write data bytes to be sent to the device. **Value** **Description** 0x1 Command requires write data bytes 0x0 No Action	RW	0x0

Bit	Name	Description	Access	Reset
14:12	numwrdatabytes	Up to 8 Data bytes may be written using this command. Value: Description 0x0: Write 1 Byte 0x1: Write 2 Byte 0x2: Write 3 Byte 0x3: Write 4 Byte 0x4: Write 5 Byte 0x5: Write 6 Byte 0x6: Write 7 Byte 0x7: Write 8 Byte	RW	0x0
11:7	numdummybytes	Set to the number of dummy bytes required This should be setup before triggering the command via the execute field of this register.	RW	0x0
1	cmdexecstat	Command execution in progress. Value: Description 0x1: Command Execution Status 0x0: No Action	RO	0x0

Document Revision History

Table 15-6: Document Revision History

Date	Version	Changes
December 2014	2014.12.15	Maintenance release
July 2014	2014.07.31	Updated address maps and register descriptions
June 2014	2014.06.30	Added address maps and register definitions
February 2014	2014.02.28	Maintenance release
December 2013	2013.12.30	Maintenance release
November 2012	1.2	Minor updates.
May 2012	1.1	Added block diagram and system integration, functional description, programming model, and address map and register definitions sections.
January 2012	1.0	Initial release.

DMA Controller 16

2014.12.15

av_5v4

This chapter describes the direct memory access controller (DMAC) contained in the hard processor system (HPS). The DMAC is used to transfer data between memory and peripherals and other memory locations in the system. The DMA controller is an instance of the ARM Corelink DMA Controller (DMA-330).

Related Information

http://infocenter.arm.com/

For more information about ARM's DMA-330 controller, refer to the *CoreLink DMA Controller DMA-330 Revision: r1p2* Technical Reference Manual on the ARM info center website

Features of the DMA Controller

The HPS provides one DMAC to handle the data transfer between memory-mapped peripherals and memories, off-loading this work from the microprocessor unit (MPU) subsystem.

The DMAC supports multiple transfer types:

- Memory-to-memory
- Memory-to-peripheral
- Peripheral-to-memory

The DMAC supports up to:

- Eight logical channels for different levels of service requirements
- 31 peripheral handshake interfaces for peripheral hardware flow control

The DMAC provides:

- An instruction processing block that enables it to process program code that controls a DMA transfer
- An ARM Advanced Microcontroller Bus Architecture (AMBA) Advanced eXtensible Interface (AXI) master interface unit to fetch the program code from system memory into its instruction cache

  Note: The AXI master interface also performs DMA data transfer. The DMA instruction execution engine executes the program code from its instruction cache and schedules read or write AXI instructions through the respective instruction queues.
- A multi-FIFO (MFIFO) data buffer that stores data that it reads, or writes, during a DMA transfer
- 11 interrupt outputs to enable efficient communication of events to the MPU subsystem

  Note: The peripheral request interfaces support the connection of DMA-capable peripherals to enable memory-to-peripheral and peripheral-to-memory transfers to occur, without intervention from the processor. Because, the HPS supports some peripherals that do not comply with ARM DMA peripheral interface protocol, adapters are added to allow these peripherals to work with the DMAC.

The DMAC supports the following interface protocols:

- Synopsys protocol
  - Serial peripheral interface (SPI)
  - Universal asynchronous receiver/transmitter (UART)
  - Inter-integrated circuit (I^2C)
  - FPGA
- ARM protocol
  - Quad SPI flash controller
  - System trace macrocell (STM)

Dual slave interfaces enable the operation of the DMA controller to be partitioned into the Secure state and Non-secure state. The network interconnect must be configured to ensure that only secure transactions can access the secure interface. The slave interfaces can access status registers and also directly execute instructions in the DMA controller.

The DMAC has the following features:

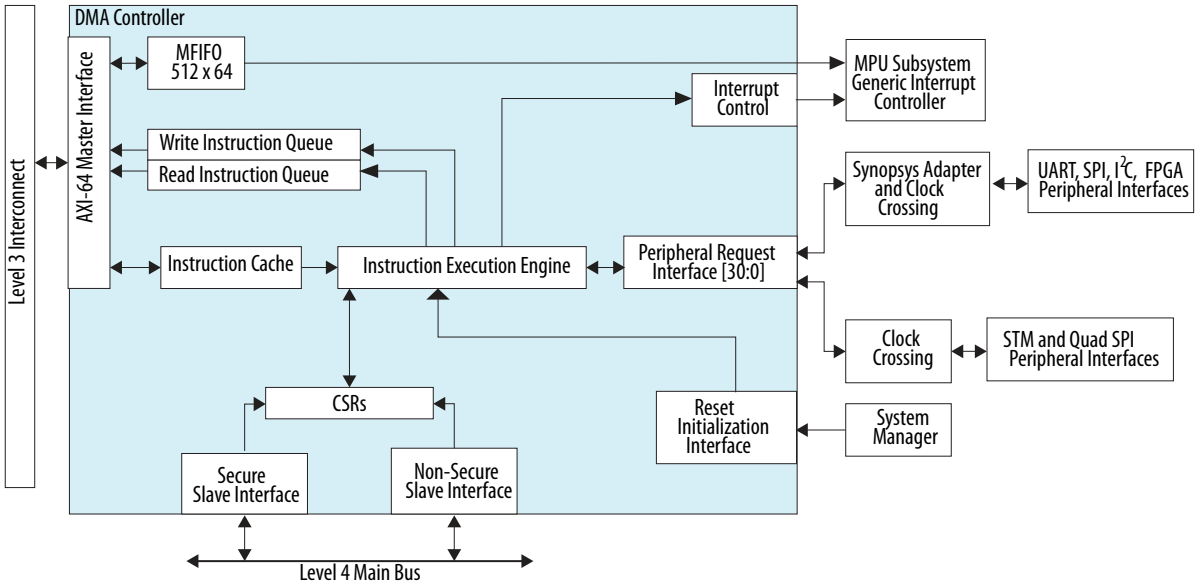
- A small instruction set that provides a flexible method of specifying the DMA operations. This architecture provides greater flexibility than the fixed capabilities of a Linked-List Item (LLI) based DMA controller.
- Supports multiple transfer types:
  - Memory-to-memory
  - Memory-to-peripheral
  - Peripheral-to-memory
  - Scatter-gather
- Supports up to eight DMA channels.
- Supports up to eight outstanding AXI read and eight outstanding AXI write transactions.
- Enables software to schedule up to 16 outstanding read and (16) outstanding write instructions.

- Supports (11) interrupt lines into the MPU subsystem:
  - One (1) for DMA thread abort
  - Eight (8) for events
  - Two (2) for MFIFO buffer ECC
- Single and double bit ECC support
- Supports 31 peripheral request interfaces:
  - Eight (8) for FPGA
  - Eight (8) for I^2C
  - Eight (8) for SPI
  - Two (2) for quad SPI
  - One (1) for System Trace Macrocell
  - Four (4) for UART

DMA Controller Block Diagram and System Integration

The following figure shows a block diagram of the DMAC and how it integrates into the rest of the HPS system.

Figure 16-1: DMA Controller Connectivity



The `l4_main_clk` clock drives the DMA controller, controller logic, and all the interfaces. The DMA controller accesses the level 3 (L3) main switch with its 64-bit AXI master interface.

The DMA controller provides the following slave interfaces:

- Non-secure slave interface
- Secure slave interface

You can use these slave interfaces to access the registers that control the functionality of the DMA controller. The DMA controller implements TrustZone secure technology with one interface operating in the Secure state and the other operating in the Non-secure state.

Functional Description of the DMA Controller

This section describes the major interfaces and components of the DMAC and its operation.

The DMAC contains an instruction processing block that processes program code to control a DMA transfer. The program code is stored in a region of system memory that the DMAC accesses using its AXI master interface. The DMAC stores instructions temporarily in an internal cache.

The DMAC has eight DMA channels. Each channel supports a single concurrent thread of DMA operation. In addition, a single DMA manager thread exists, and you can use it to initialize the DMA channel threads.

The DMAC executes one instruction per clock cycle. To ensure that it regularly executes each active thread, the DMAC alternates by processing the DMA manager thread and then a DMA channel thread. It performs a round-robin process when selecting the next active DMA channel thread to execute.

The DMAC uses variable-length instructions that consist of one to six bytes. It provides a separate program counter (PC) register for each DMA channel.

The DMAC includes a 16-line instruction cache to improve the instruction fetch performance. Each instruction cache line contains eight, four-byte words for a total cache line size of 32 bytes. The DMAC instruction cache size is therefore 16 lines times 32 bytes per line which equals 512 bytes. When a thread requests an instruction from an address, the cache performs a lookup. If a cache hit occurs, then the cache immediately provides the instruction. Otherwise, the thread is stalled while the DMAC performs a cache line fill through the AXI master interface. If an instruction spans the end of a cache line, the DMAC performs multiple cache accesses to fetch the instruction.

Note: When a cache line fill is in progress, the DMAC enables other threads to access the cache. But if another cache miss occurs, the pipeline stalls until the first line fill is complete.

When a DMA channel thread executes a load or store instruction, the DMAC adds the instruction to the relevant read or write queue. The DMAC uses these queues as an instruction storage buffer prior to it issuing the instructions on the AXI. The DMAC also contains an MFIFO data buffer in which it stores data that it reads or writes during a DMA transfer.

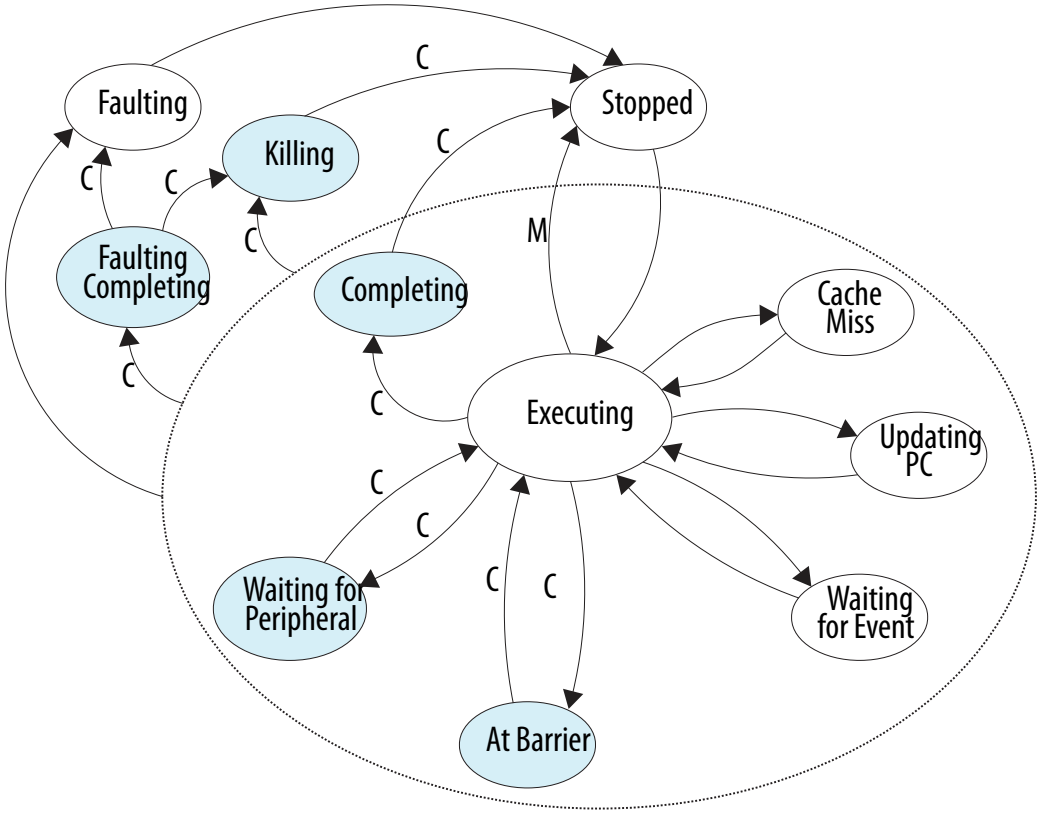
The DMAC provides multiple interrupt outputs to enable efficient communication of events to external microprocessors. The peripheral request interfaces support the connection of DMA-capable peripherals to enable memory-to-peripheral and peripheral-to-memory DMA transfers to occur without intervention from a microprocessor.

Dual slave interfaces enable the operation of the DMAC to be partitioned into the Secure state and Non-secure states. You can access status registers and also directly execute instructions in the DMAC with the slave interfaces.

Operating States

The following figure shows the transitions among operating states for the DMA manager thread and DMA channel threads. The DMAC provides a separate state machine for each thread.

Figure 16-2: Thread Operating States



In the above figure, the DMAC permits all of the following:

- Only DMA channel threads can use states shown in blue
- Arcs with no letter designator indicate state transitions for the DMA manager and DMA channel threads, otherwise use is restricted as follows:
  - C—DMA channel threads only
  - M—DMA manager thread only
- States within the dotted line can transition to the Faulting completing, Faulting, or Killing

After the DMAC exits from reset, it sets all DMA channel threads to the Stopped state, and DMA manager thread moves to the Stopped state.

The following sections describe the *Thread Operating* states:

Stopped

The thread has an invalid PC (Program Counter) and it is not fetching instructions. Depending on the thread type, you can cause the thread to move to the Executing state by all of the following:

- DMA manager thread—Issuing the DMAGO instruction through the slave interface
- DMA channel thread—Programming the DMA manager thread to execute `DMAGO` for a DMA channel thread in the Stopped state

Executing

The thread has a valid PC and therefore the DMAC includes the thread when it arbitrates. The thread can then change to one of the following states under the following conditions:

- Stopped—When the DMA manager thread executes `DMAEND`
- Cache miss—When the instruction cache does not contain the next instruction for either the DMA manager thread or the DMA channel thread
- Updating PC—When the DMAC calculates the address of the next access in the cache
- Waiting for event—When a thread executes `DMAWFE`
- At barrier—When a DMA channel thread either:
  - Executes `DMARMB`, `DMAWMB`, or `DMAFLUSHP`
  - Updates control registers that affect alignment during a DMA Cycle
- Waiting for peripheral—When a DMA channel thread executes `DMAWFP`
- Killing—When a DMA channel thread executes `DMAKILL`
- Faulting completing—For a DMA channel thread when either:
  - The thread executes an undefined or invalid instruction
  - An AXI error occurs during an instruction fetch or data transfer
- Faulting—For the DMA manager thread when either:
  - The thread executes an undefined or invalid instruction
  - An AXI error occurs during an instruction fetch

  For a DMA channel thread when a watchdog timeout abort occurs.
- Completing—When a DMA channel thread executes `DMAEND`

Cache Miss

The thread is stalled and the DMAC is performing a cache line fill. After it completes the cache fill, the thread returns to the Executing state.

Updating PC

The DMAC is calculating the address of the next access in the cache. After it calculates the PC, the thread returns to the Executing state.

Waiting For Event

The thread is stalled and is waiting for the DMAC to execute `DMASEV` using the corresponding event number. After the corresponding event occurs, the thread returns to the Executing state.

At Barrier

A DMA channel thread is stalled and the DMAC is waiting for transactions on the AXI to complete. After the AXI transactions complete, the thread returns to the Executing state.

Waiting For Peripheral

A DMA channel thread is stalled and the DMAC is waiting for the peripheral to provide the requested data. After the peripheral provides the data, the thread returns to the Executing state.

Faulting Completing

A DMA channel thread is waiting for the AXI master interface to signal that the outstanding load or store transactions are complete. After the transactions complete, the thread moves to the Faulting state.

Faulting

The thread is stalled indefinitely. The thread moves to the Stopped state when you use the `DBGCMD` register to instruct the DMAC to execute `DMAKILL` for that thread.

Killing

A DMA channel thread is waiting for the AXI master interface to signal that the outstanding load or store transactions are complete. After the transactions complete, the thread moves to the Stopped state.

Completing

A DMA channel thread is waiting for the AXI master interface to signal that the outstanding load or store transactions are complete. After the transactions complete, the thread moves to the Stopped state.

Initializing the DMAC

The DMAC provides several memory-mapped control signals that initialize its operating state when it exits from reset. The DMAC does not automatically begin executing code when it exits from reset. The system manager controls these memory-mapped control signals.

Related Information

System Manager on page 5-1

How to Set the Security State of the DMA Manager

The `boot_manager_ns` signal is the only method to set the security state of the DMA manager.

When the DMAC exits from reset, it reads the status of the `boot_manager_ns` signal and sets the security of the DMA manager.

Note: When set, the security state remains constant until a state transition on the `dma_rst_n` signal resets the DMAC.

Related Information

How to Set the Security State for the Interrupt Outputs

The DMAC provides the `boot_irq_ns[7:0]` signals to enable you to assign each `irq[x]` signal to a security state.

The `boot_irq_ns[7:0]` signals connect to the system manager. Before taking the DMA out of reset, you should program `boot_irq_ns[7:0]` through the system manager to control which interrupt bits are secure.

Note: The DMAC samples the `boot_irq_ns[7:0]` bits immediately after reset and then ignores them until the next reset.

When set, the security state of each `irq[x]` signal remains constant until a state transition on the `dma_rst_n` signal resets the DMAC.

Related Information

Security Usage on page 16-19
Describes how the security state of the irq[x] signals affects how the DMAC executes the DMAWFE and DMASEV instructions.

How to Set the Security State for a Peripheral Request Interface

The DMAC provides the signals to enable you to assign each peripheral request interface to a security state.

The `boot_periph_ns[31:0]` signals connect to the system manager. Before taking the DMA out of reset, you should program the `boot_periph_ns[31:0]` signals through the system manager to control which peripheral interfaces are secure.

Note: The DMAC samples the `boot_periph_ns[31:0]` bits immediately after reset and then ignores them until the next reset. When set, the security state of each peripheral request interface remains constant until a state transition on the `dma_rst_n` signal resets the DMAC.

Related Information

Security Usage on page 16-19
Describes the effect of the security state of the peripheral request interfaces on the execution of the DMAWFP, DMALDP, DMASTP, or DMAFLUSHP instructions by a DMA channel thread.

Using the Slave Interfaces

The slave interfaces connect the DMAC to the level 4 (L4) main bus and enable the MPU to access the registers. Using these registers, the MPU can perform the following functions:

- Access the status of the DMA manager thread
- Access the status of the DMA channel threads
- Enable or clear interrupts
- Enable events
- Execute an instruction for the DMAC by programming the following debug registers:
  - `DBGCMD` register
  - `DBGINST0` register
  - `DBGINST1` register

Issuing Instructions to the DMAC using a Slave Interface

When the DMAC is operating, you can only issue the following instructions:

- DMAGO—Starts a DMA transaction using a DMA channel that you specify
- DMASEV—Signals the occurrence of an event, or interrupt, using an event number that you specify
- DMAKILL—Terminates a thread

You must ensure that you use the appropriate slave interface, depending on the security state in which the boot_manager_ns signal initializes the DMAC. For example, if the DMAC is in the Secure state, you must issue the instruction using the secure slave interface, otherwise the DMAC ignores the instruction. You can use the secure or non-secure slave interface to start or restart a DMA channel when the DMAC is in the Non-secure state.

Note: Before you can issue instructions using the debug instruction registers or the DBGCMD register, you must read the DBGSTATUS register to ensure that debug is idle, otherwise the DMAC ignores the instructions.

The DMAC immediately processes any instructions received from a slave interface, unless the pipeline is busy processing another instruction.

Note: Prior to issuing DMAGO, you must ensure that the system memory contains a suitable program for the DMAC to execute, starting at the address that the DMAGO specifies.

Using DMAGO with the Debug Instruction Registers

The following example shows the necessary steps to start a DMA channel thread using the debug instruction registers:

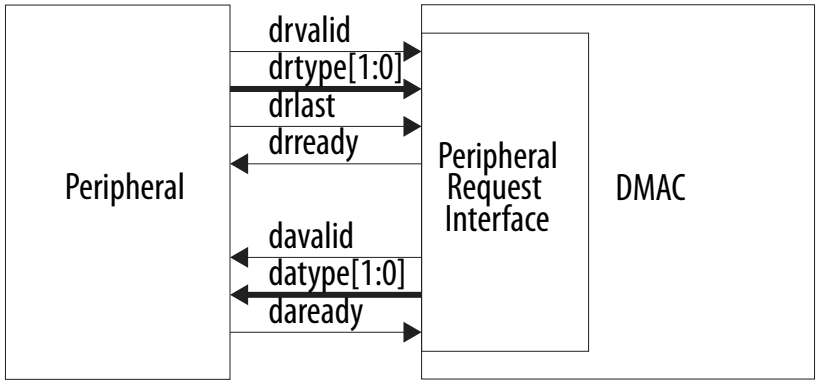
1. Create a program for the DMA channel.
2. Store the program in a region of system memory.
3. Program one of the slave interfaces on the DMAC to a DMAGO instruction as follows:
   a. Poll the DBGSTATUS register to ensure that debug is idle, and the dbgstatus bit is 0.
   b. Write to the DBGINST0 register and enter all of the following:
      - Instruction byte 0 encoding for DMAGO
      - Instruction byte 1 encoding for DMAGO
      - Debug thread bit to 0 to select the DMA manager thread
   c. Write to the DBGINST1 register with the DMAGO instruction byte [5:2] data. You must set these four bytes to the address of the first instruction in the program that is written to system memory in **step 2** above.
4. Instruct the DMAC to execute the instruction that the debug instruction registers contain by writing zero to the DBGCMD register. The DMAC starts the DMA channel thread and sets the dbgstatus bit to 1. After the DMAC completes execution of the instruction, it clears the dbgstatus bit to 0.

Peripheral Request Interface

The following figure shows that the peripheral request interface consists of a peripheral request bus and a DMAC acknowledge bus that use the prefixes:

- dr—The peripheral request bus
- da—The DMAC acknowledge bus

Figure 16-3: Request and Acknowledge Buses on the Peripheral Request Interface



The peripheral indicates the following on the request bus:

- Request a single transfer
- Request a burst transfer
- Acknowledge a flush request

The peripheral indicates the DMAC when it issues the last request of the DMA transfer sequence.

The DMAC can indicate the following on the acknowledge bus:

- When it completes the requested single transfer
- When it completes the requested burst transfer
- When it issues a flush request

You can assign a peripheral request interface to any of the DMA channels. When a DMA channel thread executes `DMAWFP`, the value programmed in the peripheral [4:0] field specifies the peripheral associated with that DMA channel.

The DMAC supports 32 peripheral request handshakes. Each request handshake can receive up to four outstanding requests, and is assigned a specific peripheral device ID. The following table lists the peripheral device ID assignments.

Table 16-1: Peripheral Request Interface Mapping

Peripheral	Request Interface ID	Protocol
FPGA 0	0	Synopsys
FPGA 1	1	Synopsys
FPGA 2	2	Synopsys
FPGA 3	3	Synopsys

UART 0 Rx	29	Synopsys
UART 1 Tx	30	Synopsys
UART 1 Rx	31	Synopsys

Request Acceptance Capability

The DMAC can accept one active request for each peripheral request interface. An active request exists when the DMAC has not started the requested AXI data transfers.

Peripheral Length Management

A peripheral can control the quantity of data that a DMA cycle contains, without the DMAC being aware of how many data transfers it contains. The peripheral controls the DMA cycle in one of the following ways:

- Selects a single transfer
- Selects a burst transfer
- Notifies the DMAC when it commences the final request in the current series

When the DMAC executes a `DMAWFP` peripheral instruction, it halts execution of the thread and waits for the peripheral to send a request. When the peripheral sends the request, the DMAC sets the request flags depending on the state of the following signals:

- `drtype_<x>[1:0]` —The DMAC sets the state of the `request_type` flag:
  - `drtype_<x>[1:0]`=b00—`request_type <x>` = Single
  - `drtype_<x>[1:0]`=b01—`request_type <x>` = Burst
- `drlast_<x>`—The DMAC sets the state of the `request_last` flag:
  - `drlast_<x>`=0—`request_last <x>` = 0
  - `drlast_<x>`=1—`request_last <x>` = 1

Note: If the DMAC executes a `DMAWFP` single or `DMAWFP` burst instruction then the DMAC sets:

- The request_type<x> flag to Single or Burst, respectively
- The request_last<x> flag to 0

`DMALPFE` is an assembler directive that forces the associated `DMALPEND` instruction to have its `nf` bit cleared, creating a program loop that does not use a loop counter to terminate the loop.

The DMAC exits the loop when the `request_last` flag is set.

The DMAC conditionally executes the following instructions, depending on the state of the request_type and request_last flags:

- **DMALD , DMAST , DMALPEND** - When these instructions use the optional B|S suffix then the DMAC executes a DMANOP if the request_type flag does not match.
- **DMALDP<B|S> , DMASTP<B|S>** - The DMAC executes a DMANOP if the request_type <x> flag does not match the B|S.
- **DMALPEND** - When the nf bit is 0, the DMAC executes a DMANOP if the request_last flag is set.

Use the DMALDB, DMALDPB, DMASTB and DMASTPB instructions if you require the DMAC to issue a burst transfer when the DMAC receives a burst request. The values in the CCR*n* register control the amount of data that the DMAC transfers.

Use the DMALDS, DMALDPS, DMASTS and DMASTPS instructions if you require the DMAC to issue a single transfer when the DMAC receives a single request. The DMAC ignores the value of the src_burst_len and dst_burst_len fields in the CCR*n* register and sets the arlen[3:0] or awlen[3:0] buses to 0x0.

DMAC Length Management

The DMAC controls the total amount of data. The peripheral uses the peripheral request interface to notify the DMAC when it requires the DMAC to transfer data to or from the peripheral. The DMA channel thread controls how the DMAC responds to the peripheral requests.

The following constraints apply to DMAC length management:

- The total quantity of data for all the single requests from a peripheral must be less than the quantity of data for a burst request for that peripheral.

  Note: The CCRn register controls how much data is transferred for a burst request and a single request. Altera recommends that you do not update a CCRn register when a transfer is in progress for channel n.

- After the peripheral sends a burst request, the peripheral must not send a single request until the DMAC acknowledges that the burst request is complete.

Program the DMAWFP single instruction when you require the program thread to halt execution until the peripheral request interface receives any request type.

- Single— If the head entry in the request FIFO buffer is a single request type, the DMAC pops the entry from the FIFO buffer and continues program execution.
- Burst—If the head entry in the request FIFO buffer is a burst request type, the DMAC leaves the entry in the FIFO buffer and continues program execution.

  Note: The burst request entry remains in the request FIFO buffer until the DMAC executes a DMAWFP burst instruction or a DMAFLUSHP instruction.

Program the DMAWFP burst instruction when you require the program thread to halt execution until the peripheral request interface receives a burst request.

- Single—If the head entry in the request FIFO buffer is a single request type, the DMAC removes the entry from the FIFO buffer and continues program execution.
- Burst—If the head entry in the request FIFO buffer is a burst request type, the DMAC pops the entry from the FIFO buffer and continues program execution.

Program the DMALDP instruction when you require the DMAC to send an acknowledgment to the peripheral when it completes the AXI read transfers. Similarly, use the DMASTP instruction when you require the DMAC to send an acknowledgment to the peripheral when it completes the AXI write transfers. The DMAC uses the acknowledge bus to signal a transfer acknowledgment to the peripheral.

Note: The DMAC sends an acknowledgment for a read transaction when the rvalid and rlast signals are high and for a write transaction when bvalid signal is high. The DMAC might send an acknowledgment to the peripheral while the transfer of write data to the end destination is still in progress.

Use the DMAFLUSHP instruction to reset the request FIFO buffer for the peripheral request interface. After the DMAC executes DMAFLUSHP, it ignores peripheral requests until the peripheral acknowledges the flush request. This protocol enables the DMAC and peripheral to synchronize with each other.

ARM Protocol

The DMA peripheral request interface communicates with peripherals by either the ARM protocol or the Synopsys protocol.

For peripherals using the ARM protocol, clock-crossing logic is the only logic between the DMA and the peripheral.

Synopsys Protocol Overview

The Synopsys protocol is used for the hardware flow control that is not the same as the ARM® protocol used by the DMA-330 core.

For peripherals using the Synopsys protocol, clock-crossing logic and protocol adaptation logic exist between the DMA and the peripheral.

The Synopsys protocol is described, below:

- A single transfer line is asserted when the peripheral requests a single data transfer.
- A burst transfer line is asserted when the peripheral requests a burst transfer.

  Note: The burst transfer size must be identically set in both the DMA and peripheral to avoid potential data loss or corruption.
- The single and burst transfer lines must remain asserted until the DMA issues an acknowledge back to the peripheral.

  Note: If the peripheral must be reset, then the DMA should be instructed to flush the request which is translated into an acknowledge by the Synopsys protocol adapter.
- When a transfer is acknowledged, the peripheral must deassert the burst and single request lines for the duration of the acknowledgment.

Note: A transmit or receive request is not complete until the DMA issues an acknowledge back to the peripheral.

Using Events and Interrupts

The DMAC can support eight events and interrupts. The INTEN register determines whether each event-interrupt resource is an event or an interrupt.

When the DMAC executes a DMASEV instruction, it modifies the event-interrupt resource that you specify. The INTEN register sets the event-interrupt resource to function as an:

- **Event**—The DMAC generates an event for the specified event-interrupt resource. When the DMAC executes a DMAWFE instruction for the same event-interrupt resource then it clears the event.
- **Interrupt**—The DMAC sets the irq <event_num> signal high, where <event_num> is the number of the specified event resource. To clear the interrupt you must write to the INTCLR register.

Using an Event to Restart DMA Channels

When you program the INTEN register to generate an event, you can use the DMASEV and DMAWFE instructions to restart one or more DMA channels.

DMAC executes DMAWFE before DMASEV

To restart a single DMA channel:

1. The first DMA channel executes DMAWFE and then stalls while it waits for the event to occur.
2. The other DMA channel executes DMASEV using the same event number generating an event and restarting the first DMA channel. The DMAC clears the event, one clock cycle after it executes DMASEV.

You can program multiple channels to wait for the same event. For example, if four DMA channels have all executed DMAWFE for event 2, and another DMA channel executes DMASEV for event 2, the four DMA channels all restart at the same time. The DMAC clears the event, one clock cycle after it executes DMASEV.

DMAC executes DMASEV before DMAWFE

If the DMAC executes DMASEV before another channel executes DMAWFE, the event remains pending until the DMAC executes DMAWFE. When the DMAC executes DMAWFE, it halts execution for one aclk clock cycle, clears the event and then continues execution of the channel thread.

For example, if the DMAC executes DMASEV 6 and none of the other threads have executed DMAWFE 6, then the event remains pending. If the DMAC executes the DMAWFE 6 instruction for channel 4 and then executes the DMAWFE 6 instruction for channel 3, the following actions occur:

1. The DMAC halts execution of the channel 4 thread for one clock cycle.
2. The DMAC clears event 6.
3. The DMAC resumes execution of the channel 4 thread.
4. The DMAC halts execution of the channel 3 thread and the thread stalls while it waits for the next occurrence of event 6.

Interrupting the MPU Subsystem

The DMAC provides the irq[x] signals for use as active-high level-sensitive interrupts to the MPU subsystem. When you program the INTEN register to generate an interrupt, after the DMAC executes DMASEV, it sets the corresponding irq[x] signal high.

The MPU subsystem can clear the interrupt by writing to the INTCLR register.

Note: Executing DMAWFE does not clear an interrupt.

If you use the DMASEV instruction to notify a microprocessor when the DMAC completes a DMALD or DMAST instruction then you should insert a memory barrier instruction before the DMASEV. Otherwise the DMAC might signal an interrupt before the AXI transfers complete.

The following program shows the example of Memory Barrier Instruction.

```
DMALD
DMAST
# Issue a write memory barrier
# Wait for the AXI write transfer to complete before the DMAC
# can send an interrupt
DMAWMB
# The DMAC sends the interrupt
DMASEV
```

Aborts

Abort Types

An abort can be classified as either precise or imprecise, depending on whether the DMAC provides an abort handler with the precise state of the DMAC when the abort occurs.

- Precise Abort - The DMAC updates the PC register with the address of the instruction that created the abort.
- Imprecise Abort - The PC register might contain the address of an instruction that did not cause the abort to occur.

Abort Sources

The DMAC indicates a precise abort under any of the following conditions:

- A DMA channel thread in the Non-secure state attempts to program its CCRn register and generate a secure AXI transaction.
- A DMA channel thread in the Non-secure state executes DMAWFE or DMASEV for an event that is set as secure. The boot_irq_ns memory-mapped control signals initialize the security state for an event.

Note: For each event, the INTEN register controls if the DMAC generates an event or signals an interrupt.

- A DMA channel thread attempts to execute DMAST but the DMAC calculates that when it eventually performs the store, the MFIFO buffer contains insufficient data to enable it to complete the store.
- A DMA channel thread in the Non-secure state executes DMAWFP, DMALDP, DMASTP, or DMAFLUSHP for a peripheral request interface that is set as secure. The boot_periph_ns memory-mapped control signals initialize the security state for a peripheral request interface.
- A DMA manager thread in the Non-secure state executes DMAGO to attempt to start a secure DMA channel thread.
- The DMAC receives an ERROR response on the AXI master interface when it performs an instruction fetch.
- A thread executes an undefined instruction.
- A thread executes an instruction with an operand that is invalid for the configuration of the DMAC.

Note: When the DMAC signals a precise abort, the instruction that triggers the abort is not executed. Instead, the DMAC executes a DMANOP.

The DMAC signals an imprecise abort under the following conditions:

- The DMAC receives an ERROR response on the AXI master interface when it performs a data load.
- The DMAC receives an ERROR response on the AXI master interface when it performs a data store.
- A DMA channel thread executes `DMALD` or `DMAST`, and the MFIFO buffer is too small to hold the required amount of data.
- A DMA channel thread executes `DMAST` but the thread has not executed sufficient `DMALD` instructions.
- A DMA channel thread locks up because of resource starvation, and this causes the internal watchdog timer to time out.

Watchdog Abort

The DMAC can lock up if one or more DMA channel programs are running and the MFIFO buffer is too small to satisfy the storage requirements of the DMA programs.

The DMAC contains logic to prevent it from remaining in a state where it is unable to complete a DMA transfer.

The DMAC detects a lock up when all of the following conditions occur:

- Load queue is empty.
- Store queue is empty.
- All of the running channels are prevented from executing a `DMALD` instruction either because the MFIFO buffer does not have sufficient free space or another channel owns the load-lock.

When the DMAC detects a lockup, it signals an interrupt and can also abort the contributing channels. The DMAC behavior depends on the state of the `wd_irq_only` bit in the `WD` register, if:

- `wd_irq_only=0`—The DMAC aborts all of the contributing DMA channels and sets the `irq_abort` signal high.
- `wd_irq_only=1`—The DMAC sets the `irq_abort` signal high.

Related Information

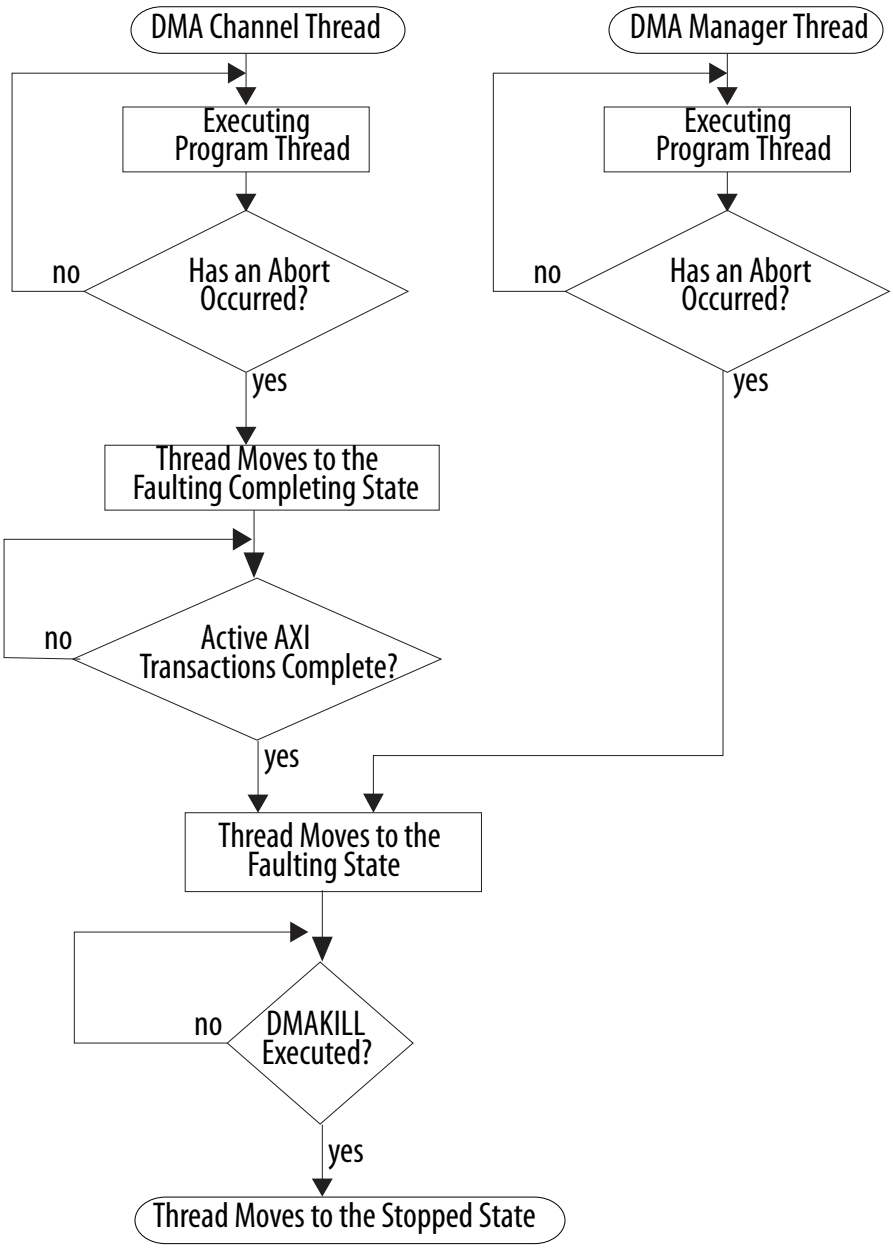
Resource Sharing Between DMA Channels on page 16-24

Abort Handling

The architecture of the DMAC is not designed to recover from an abort. You must use an external agent, such as the MPU, to terminate a thread when an abort occurs.

The following figure shows the operating states for the DMA channel and DMA manager threads after an abort occurs.

Figure 16-4: Abort Process



After an abort occurs, the action of the DMAC depends on the thread type:

- DMA channel thread—The thread immediately moves to the Faulting completing state. In this state, the DMAC performs the following operations:
  - Sets the `irq_abort` signal high.
  - Stops executing instructions for the DMA channel.
  - Invalidates all cache entries for the DMA channel updates the `CPC`*n* register to contain the address of the aborted instruction provided that the abort is precise.
  - Does not generate AXI accesses for any instructions remaining in the read queue and write queue.
  - Permits currently active AXI transactions to complete.

  Note: After the transactions for the DMA channel finish, the thread moves to the Faulting state.
- DMA manager thread—The thread immediately moves to the Faulting state and the DMAC sets the `irq_abort` signal high.

  The external agent can respond to the assertion of the `irq_abort` signal by all of the following:
  - Reading the status of the `FSRD` register to determine if the DMA manager is Faulting. In the Faulting state, the `FSRD` register provides the cause of the abort.
  - Reading the status of the `FSRC` register to determine if a DMA channel is Faulting. In the Faulting state, the `FSRC` register provides the cause of the abort.

  To enable a thread in the Faulting state to move to the Stopped state, the external agent must:
  - Program the `DBGINST0` register with the encoding for the `DMAKILL` instruction.
  - Write to the `DBGCMD` register.

  Note: If the aborted thread is secure, you must use the secure slave interface to update these registers.

  After a thread in the Faulting state executes `DMAKILL`, it moves to the Stopped state.

Security Usage

When the DMAC exits from reset, the status of the configuration signals configures the security for:

- DMA manager thread—The `DNS` bit in the DSR register returns the security state of the DMA manager thread.
- Events and interrupts—The `INS` bit in the `CR3` register returns the security state of the event-interrupt resources.
- Peripheral request interfaces—The `PNS` bit in the `CR4` register returns the security state of these interfaces.

Additionally, each DMA channel thread contains a dynamic non-secure bit, `CNS`, that is valid when the channel is not in the Stopped state.

DMA Manager Thread in Secure State

If the DNS bit is 0, the DMA manager thread operates in the Secure state and performs only secure instruction fetches. When a DMA manager thread in the Secure state processes:

- DMAGO—The DMAC uses the status of the ns bit, to set the security state of the DMA channel thread by writing to the CNS bit for that channel.
- DMAWFE—The DMAC halts execution of the thread until the event occurs. When the event occurs, the DMAC continues execution of the thread, irrespective of the security state of the corresponding INS bit.
- DMASEV—The DMAC sets the corresponding bit in the INT_EVENT_RIS register, irrespective of the security state of the corresponding INS bit.

DMA Manager Thread in Non-Secure State

If the DNS bit is 1, the DMA manager thread operates in the Non-secure state, and it only performs non-secure instruction fetches. When a DMA manager thread in the Non-secure state processes:

DMAGO - The DMAC uses the status of the ns bit to control if it starts a DMA channel thread.

- If ns = 0, then the DMAC does not start a DMA channel thread and instead it:
  - Executes an NOP
  - Sets the FSRD register
  - Sets the dmago_err bit in the FTRD register
  - Moves the DMA manager to the Faulting state
- If ns = 1, then the DMAC starts a DMA channel thread in the non-secure state and programs the CNS bit to be non-secure.

DMAWFE - The DMAC uses the status of the corresponding INS bit in the CR3 register to control whether it waits for the event.

- If INS = 0, then the event is in the secure state. The DMAC:
  - Executes an NOP
  - Sets the FSRD register
  - Sets the mgr_evnt_err bit in the FTRD register
  - Moves the DMA manager to the Faulting state
- If INS = 1, then the event is in the non-secure state. The DMAC halts execution of the thread and waits for the event to occur.

DMASEV - The DMAC uses the status of the corresponding INS bit in the CR3 register to control if it creates the event interrupt.

- If INS = 0, then the event-interrupt resource is in the Secure state. The DMAC:
  - Executes a NOP
  - Sets the FSRD register
  - Sets the mgr_evnt_err bit in the FTRD register
  - Moves the DMA manager to the Faulting state
- If INS = 1, then the event-interrupt resource is in the non-secure state. The DMAC creates the event interrupt.

DMA Channel Thread in Secure State

When the CNS bit is 0, the DMA channel thread is programmed to operate in the secure state and to only perform secure instruction fetches.

When a DMA channel thread in the secure state processes the following instructions:

- DMAWFE - The DMAC halts execution of the thread until the event occurs. When the event occurs, the DMAC continues execution of the thread, regardless of the security state of the corresponding INS bit in the CR3 register.
- DMASEV - The DMAC creates the event interrupt, regardless of the security state of the corresponding INS bit in the CR3 register.
- DMAWFP - The DMAC halts execution of the thread until the peripheral signals a DMA request at which point the DMAC continues execution of the thread, regardless of the security state of the corresponding PNS bit in the CR4 register.
- DMALDP and DMASTP - The DMAC sends a message to the peripheral to communicate that data transfer is complete, regardless of the security state of the corresponding PNS bit in the CR4 register.
- DMAFLUSHP - The DMAC clears the state of the peripheral and sends a message to the peripheral to resend its level status, regardless of the security state of the corresponding PNS bit in the CR4 register.

When a DMA channel thread is in the Secure state, it enables the DMAC to perform secure and non-secure AXI accesses.

DMA Channel Thread in Non-Secure State

When the CNS bit is 1, the DMA channel thread is programmed to operate in the non-secure state and to only perform non-secure instruction fetches.

When a DMA channel thread in the Non-secure state processes the following instructions:

- DMAWFE - The DMAC uses the status of the corresponding INS bit in the CR3 register, to control if it waits for the event.
  - If INS =0, then the event is in the Secure state. The DMAC:
    - Executes an NOP
    - Sets the appropriate bit in the FSRC register corresponding to the DMA channel number
    - Sets the ch_evnt_err bit in the FTRn register
    - Moves the DMA channel to the Faulting completing state
  - If INS =1, then the event is in the Non-secure state. The DMAC halts execution of the thread and waits for the event to occur.
- DMASEV - The DMAC uses the status of the corresponding INS bit in the CR3 register, to control if it creates the event.
  - If INS =0, then the event-interrupt resource is in the Secure state. The DMAC:
    - Executes an NOP
    - Sets the appropriate bit in the FSRC register corresponding to the DMA channel number
    - Sets the ch_evnt_err bit in the FTRn register
    - Moves the DMA channel to the Faulting completing state
  - If INS =1, then the event-interrupt resource is in the Non-secure state. The DMAC creates the event interrupt.
- DMAWFP - The DMAC uses the status of the corresponding PNS bit in the CR4 register, to control if it waits for the peripheral to signal a request.
  - If PNS =0, then the peripheral is in the Secure state. The DMAC:
    - Executes an NOP
    - Sets the appropriate bit in the FSRC register corresponding to the DMA channel number
    - Sets the ch_periph_err bit in the FTRn register
    - Moves the DMA channel to the Faulting completing state
  - If PNS =1, then the peripheral is in the Non-secure state. The DMAC halts execution of the thread and waits for the peripheral to signal a request.
- DMALDP and DMASTP - The DMAC uses the status of the corresponding PNS bit in the CR4 register, to control if it sends an acknowledgement to the peripheral.
  - If PNS =0, then the peripheral is in the Secure state. The DMAC:
    - Executes an NOP
    - Sets the appropriate bit in the FSRC register corresponding to the DMA channel number
    - Sets the ch_periph_err bit in the FTRn register
    - Moves the DMA channel to the Faulting completing state
  - If PNS =1, then the peripheral is in the Non-secure state. The DMAC sends a message to the peripheral to communicate when the data transfer is complete.
- DMAFLUSHP - The DMAC uses the status of the corresponding PNS bit in the CR4 register, to control if it sends a flush request to the peripheral.
  - If PNS =0, then the peripheral is in the Secure state. The DMAC:
    - Executes an NOP
    - Sets the appropriate bit in the FSRC register corresponding to the DMA channel number
    - Sets the ch_periph_err bit in the FTRn register
    - Moves the DMA channel to the Faulting completing state
  - If PNS =1, then the peripheral is in the non-secure state. The DMAC clears the state of the peripheral and sends a message to the peripheral to resend its level status.

When a DMA channel thread is in the non-secure state, and a DMAMOV CCR instruction attempts to program the channel to perform a secure AXI transaction, the DMAC:

1. Executes a DMANOP
2. Sets the appropriate bit in the FSRC register corresponding to the DMA channel number
3. Sets the ch_rdwr_err bit in the FTR*n* register
4. Moves the DMA channel thread to the Faulting completing state

Programming Restrictions

Certain restrictions apply when programming the DMAC.

Fixed Unaligned Bursts

The DMAC does not support fixed unaligned bursts. The DMAC treats the following conditions as programming errors:

- **Unaligned read**
  - src_inc field is 0 in the CCRn register.
  - The SARn register contains an address that is not aligned to the size of data that the src_burst_size field contains.
- **Unaligned write**
  - dst_inc field is 0 in the CCRn register.
  - The DARn register contains an address that is not aligned to the size of data that the dst_burst_size field contains.

Endian Swap Size Restrictions

If you program the endian_swap_size field in the CCRn register, to enable a DMA channel to perform an endian swap, then you must set the corresponding SAR register and the corresponding DARn register to contain an address that is aligned to the size that the endian_swap_size field specifies before executing any DMALD or DMAST instructions.

Note: If you update any of endian_swap_size, SARn, or DARn, for example, using a DMAADDH SAR instruction, then you must ensure that the SARn and DARn registers contain an address aligned to the size that the endian_swap_size field specifies before executing any additional DMALD or DMAST instructions.

If you program the src_inc field in the CCR register to use a fixed address, you must program the src_burst_size field to select a burst size that is greater than or equal to the value that the endian_swap_size field specifies. Similarly, if you program the dst_inc field to select a fixed destination address, you must program the dst_burst_size field to select a burst size that is greater than or equal to the value that the endian_swap_size field specifies.

If you program the dst_inc field in the CCRn register to use an incrementing address, you must program the CCRn register so that dst_burst_len times dst_burst_size is a multiple of endian_swap_size. For example, if endian_swap_size = 2, 32-bit, and dst_burst_size = 1, 2 bytes per beat, then you can program dst_burst_len = 1, 3, 5, ..., 15, that is 2, 4, 6, ..., 16 transfers.

Updating DMA Channel Control Registers During a DMA Cycle

Prior to the DMAC executing a sequence of DMALD and DMAST instructions, the values you program in to the CCRn register, SARn register, and DARn register control the data byte lane manipulation that the DMAC performs when it transfers the data from the source address to the destination address.

You can update these registers during a DMA cycle, but if you change certain register fields, then the DMAC may discard data. The following sections describe the register fields that could have a detrimental impact on a data transfer.

Updates that affect the destination address

If you use a DMAMOV instruction to update the DARn register or CCRn register part way through a DMA cycle, then there may be a discontinuity in the destination data stream.

A discontinuity occurs if you change any of the following:

- endian_swap_size field.
- dst_inc bit.
- dst_burst_size field when dst_inc = 0, that is, fixed-address burst.
- DARn register so that it modifies the destination byte lane alignment. Because the bus width is 64 bits, you change bits [2:0] in the DARn register.

When a discontinuity in the destination data stream occurs, the DMAC:

1. Halts execution of the DMA channel thread.
2. Completes all outstanding read and write operations for the channel. That is, as if the DMAC were executing DMARMB and DMAWMB.
3. Discards any residual MFIFO buffer data for the channel.
4. Resumes execution of the DMA channel thread.

Updates that affect the source address

If you use a DMAMOV instruction to update the SARn register or CCRn register part way through a DMA cycle then this might cause a discontinuity in the source data stream.

A discontinuity occurs if you change any of the following:

- src_inc bit.
- src_burst_size field.
- SAR register so that it modifies the source byte lane alignment. Because the bus width is 64 bits, you change bits [2:0] in the SAR register.

When a discontinuity in the source data stream occurs, the DMAC:

1. Halts execution of the DMA channel thread.
2. Completes all outstanding read operations for the channel. That is, as if the DMAC were executing DMARMB
3. Resumes execution of the DMA channel thread. No data is discarded from the MFIFO buffer.

Resource Sharing Between DMA Channels

DMA channel programs share the MFIFO buffer data storage resource. You must not start a set of concurrently running DMA channel programs with a resource requirement that exceeds 512, the size of

the MFIFO buffer. If you exceed this limit then the DMAC might lock up and generate a Watchdog abort, refer to "Watchdog Abort".

The DMAC includes a mechanism called the *load lock* to ensure that the shared MFIFO buffer resource is used correctly. The load-lock is either owned by one channel or it is free. The channel that owns the load-lock can execute `DMALD` instructions successfully. A channel that does not own the load-lock pauses at a `DMALD` instruction until it takes ownership of the load-lock.

A channel claims ownership of the load lock when:

- It executes a `DMALD` or `DMALDP` instruction
- No other channel currently owns the load-lock.

A channel releases ownership of the load-lock when any of the following occur:

- It executes a `DMAST`, `DMASTP`, or `DMASTZ`
- It reaches a barrier, that is, it executes `DMARMB` or `DMAWMB`
- It waits, that is, it executes `DMAWFP` or `DMAWFE`
- It terminates normally, that is, it executes `DMAEND`
- It aborts for any reason, including `DMAKILL`.

The MFIFO buffer resource usage of a DMA channel program is measured in MFIFO buffer entries, and rises and falls as the program proceeds. The MFIFO buffer resource requirement of a DMA channel program is described using a *static requirement* and a *dynamic requirement* which are affected by the load-lock mechanism.

The static requirement is defined to be the maximum number of MFIFO buffer entries that a channel is currently using before that channel does one of the following:

- Executes a WFP or WFE instruction
- Claims ownership of the load-lock.

The dynamic requirement is defined to be the difference between the static requirement and the maximum number of MFIFO buffer entries that a channel program uses at any time during its

To calculate the total MFIFO buffer requirement, add the largest dynamic requirement to the sum of all the static requirements.

To avoid DMAC lockup, the total MFIFO buffer requirement of the set of channel programs must be equal to or less than 512, the MFIFO buffer depth.

Clocks and Resets

Clock

The DMA controller operates on the `l4_main_clk` input.

Related Information

Clock Manager on page 2-1

Resets

The DMA controller has nine reset signals. The reset manager drives `dma_rst_n` signal to the DMA controller on a cold or warm reset. The reset manager drives the `dma_periph_if_rst_n[7:0]` signals to reset the eight FPGA PRIs.

Table 16-2: Reset inputs to the DMA controller

Reset Signal	Description
`dma_rst_n`	Resets DMA controller
`dma_periph_if_rst_n[7:0]`	Resets the eight FPGA peripheral request interfaces

Related Information

Reset Manager on page 3-1

Taking the DMA Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the MPU boots up, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

Related Information

Reset Manager on page 3-1

Constraints and Limitations of Use

DMA Channel Arbitration

The DMAC uses a round-robin scheme to serve the active DMA channels. To ensure that the DMAC continues to serve the DMA manager, it always serves the DMA manager prior to serving the next DMA channel.

Note: You cannot alter the arbitration process of the DMAC.

DMA Channel Prioritization

The DMAC responds to all active DMA channels with equal priority. You cannot increase the priority of a DMA channel over any other DMA channels.

Instruction Cache Latency

When a cache miss occurs, most of the delay is introduced by the memory containing the DMA code; the DMAC adds minimal delay.

AXI Data Transfer Size

The DMAC can only perform data accesses up to 64 bits in width. If you program the `src_burst_size` or `dst_burst_size` fields to be larger, the DMAC indicates a precise abort.

Related Information

Abort Sources on page 16-16

AXI Bursts Crossing 4 KB Boundaries

The AXI specification does not permit AXI bursts to cross 4 KB address boundaries. If you program the DMAC with a combination of burst start address, size, and length that would cause a single burst to cross a 4 KB address boundary, then the DMAC generates a pair of bursts with a combined length equal to that specified. This operation is transparent to the DMAC channel thread program so that, for example, the DMAC responds to a single `DMALD` instruction by generating the appropriate pair of AXI read bursts.

AXI Burst Types

You can program the DMAC to generate only fixed-address or incrementing-address burst types for data accesses. It does not generate wrapping-address bursts for data accesses or for instruction fetches.

AXI Write Addresses

The DMAC can issue up to eight outstanding write addresses. The DMAC does not issue a write address until it has read in all of the data bytes required to fulfill that write transaction.

AXI Write Data Interleaving

The DMAC does not generate interleaved write data. All write data beats for one write transaction are output before any write data beat for the next write transaction.

DMA Controller Programming Model

Instruction Syntax Conventions

The following conventions are used in assembler syntax prototype lines and their subfields:

- < > - Any item bracketed by < and > is mandatory. A description of the item and of how it is encoded in the instruction is supplied by subsequent text.
- [ ] - Any item bracketed by [and] is optional. A description of the item and of how its presence or absence is encoded in the instruction is supplied by subsequent text.
- " " (spaces) - To separate items, single spaces are used for clarity. When a space is obligatory in the assembler syntax, two or more consecutive spaces are used.

Instruction Set Summary

The DMAC instructions:

- Indicate a DMA prefix, to provide a unique name-space
- Have 8-bit opcodes that might use a variable data payload of 0, 8, 16, or 32 bits
- Indicate suffixes that are consistent.

DMAWFP	Wait For Peripheral	No	Yes	**DMAWFP** on page 16-42
DMAWMB	Write Memory Barrier	No	Yes	**DMAWMB** on page 16-43

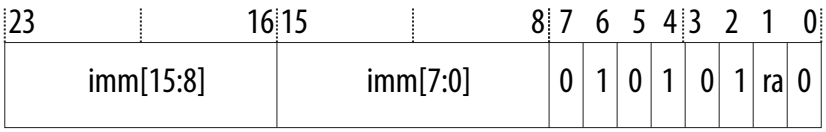
Instructions

DMAADDH

Add Halfword adds an immediate 16-bit value to the SARn register or DARn register, for the DMA channel thread. This enables the DMAC to support two-dimensional DMA operations.

Note: The immediate unsigned 16-bit value is zero-extended before the DMAC adds it to the address, using 32-bit addition. The DMAC discards the carry bit so that addresses wrap from 0xFFFFFFFF to 0x00000000.

Figure 16-5: DMAADDH Instruction Encoding



Assembler syntax

```
DMAADDH <address_register>, <16-bit bit immediate>
```

where:

`<address_register>` Selects the address register to use. It must be either:

- SAR SAR*n* register and sets `ra` to 0
- DAR DAR*n* register and sets `ra` to 1

`<16-bit immediate>` The immediate value to be added to the `<address_register>`.

Operation

You can only use this instruction in a DMA channel thread.

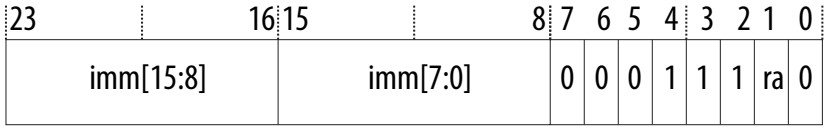
DMAADNH

Add Negative Halfword adds an immediate negative 16-bit value to the SARn register or DARn register, for the DMA channel thread. This enables the DMAC to support two-dimensional DMA operations, or reading or writing an area of memory in a different order to naturally incrementing addresses.

Note: The immediate unsigned 16-bit value is one-extended to 32 bits, to create a value that is the two's complement representation of a negative number between -65536 and -1, before the DMAC adds it to the address using 32-bit addition. The DMAC discards the carry bit so that addresses wrap from

0xFFFFFFFF to 0x00000000. The net effect is to subtract between 65536 and 1 from the current value in the source or destination address register.

Figure 16-6: DMAADNH Encoding



Assembler syntax

`DMAADNH <address_register>, <16 -bit immediate>`

where:

`<address_register>` Selects the address register to use. It must be either:

`SAR SAR`*n* register and sets `ra` to 0

`DAR DAR`*n* register and sets `ra` to 1

`<16- bit immediate>` The immediate value to be added to the `<address_register>`.

Note: You should specify the 16-bit immediate as the number that is to be represented in the instruction encoding. For example, `DMAADNH DAR`, 0xFFF0 causes the value 0xFFFFFFF0 to be added to the current value of the Destination Address register, effectively subtracting 16 from the `DAR`.

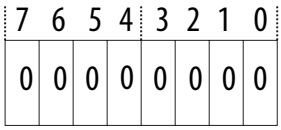
Operation

You can only use this instruction in a DMA channel thread.

DMAEND

End signals to the DMAC that the DMA sequence is complete. After all DMA transfers are complete for the DMA channel, the DMAC moves the channel to the Stopped state. It also flushes data from the MFIFO buffer and invalidates all cache entries for the thread.

Figure 16-7: DMAEND Instruction Encoding



Assembler syntax

`DMAEND`

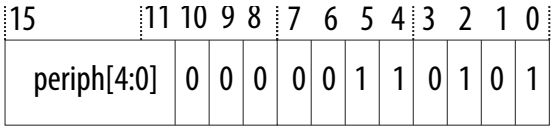
Operation

You can use the instruction with the DMA manager thread and the DMA channel thread.

DMAFLUSHP

Flush Peripheral clears the state in the DMAC that describes the contents of the peripheral and sends a message to the peripheral to resend its level status.

Figure 16-8: DMAFLUSHP Instruction Encoding



Assembler syntax

`DMAFLUSHP <peripheral>`

where:

`<peripheral>` 5-bit immediate, value 0-31

Operation

You can only use this instruction in a DMA channel thread.

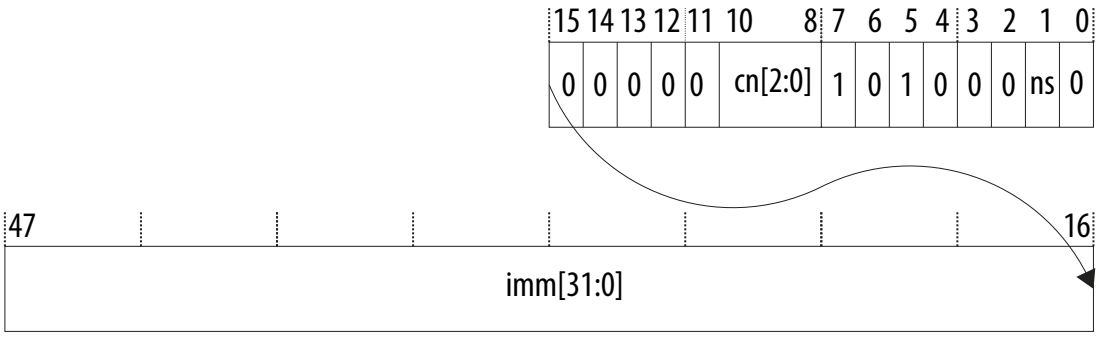
DMAGO

When the DMA manager executes Go for a DMA channel that is in the Stopped state, it performs the following steps on the DMA channel:

1. Moves a 32-bit immediate into the program counter
2. Sets its security state
3. Updates it to the Executing state.

Note: If a DMA channel is not in the Stopped state when the DMA manager executes `DMAGO` then the DMAC does not execute `DMAGO` but instead it executes `DMANOP`.

Figure 16-9: DMAGO Instruction Encoding



Assembler syntax

`DMAGO <channel_number>, <32- bit_immediate> [, ns]`

where:

`<channel_number>` Selects a DMA channel. It must be one of:

`C0` DMA channel 0

`C1` DMA channel 1

`C2` DMA channel 2

C3 DMA channel 3

C4 DMA channel 4

C5 DMA channel 5

C6 DMA channel 6

C7 DMA channel 7

Note: If you provide a channel number that is not available for your configuration of the DMAC, the DMA manager thread aborts.

<32- bit_immediate> The immediate value that is written to the CPC*n* register for the selected <channel_number>.

[ns]

- If ns is present, the DMA channel operates in the Non-secure state.
- Otherwise, the execution of the instruction depends on the security state of the DMA manager:

DMA manager is in the Secure state—DMA channel operates in the Secure state.

DMA manager is in the Non-secure state—The DMAC aborts.

Operation

You can only use this instruction with the DMA manager thread.

DMAKILL

Kill instructs the DMAC to immediately terminate execution of a thread. Depending on the thread type, the DMAC performs the following steps:

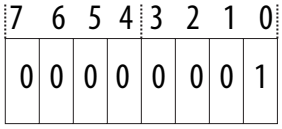
DMA Manager Thread

1. Invalidates all cache entries for the DMA manager.
2. Moves the DMA manager to the Stopped state.

DMA Channel Thread

1. Moves the DMA channel to the Killing state.
2. Waits for AXI transactions, with an ID equal to the DMA channel number, to complete.
3. Invalidates all cache entries for the DMA channel.
4. Remove all entries in the MFIFO buffer for the DMA channel.
5. Remove all entries in the read buffer queue and write buffer queue for the DMA channel.
6. Moves the DMA channel to the Stopped state.

Figure 16-10: DMAKILL Instruction Encoding



Assembler syntax

DMAKILL

Operation

You can use the instruction with the DMA manager thread and the DMA channel thread.

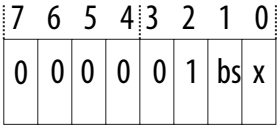
Note: You must not use the DMAKILL instruction in DMA channel programs. To issue a DMAKILL instruction, use the DBGINST0 register.

DMALD[S | B]

Load instructs the DMAC to perform a DMA load, using AXI transactions that the source address registers and channel control registers specify. It places the read data into the MFIFO buffer and tags it with the corresponding channel number. DMALD is an unconditional instruction but DMALDS and DMALDB are conditional on the state of the request_type flag. If the src_inc bit in the channel control registers is set to incrementing, the DMAC updates the source address registers after it executes DMALD[S|B].

Note: The DMAC sets the value of request_type when it executes a DMAWFP instruction.

Figure 16-11: DMALD[S|B] Instruction Encoding



Assembler syntax

```
DMALD[S|B]
```

where:

[S] If S is present, the assembler sets bs to 0 and x to 1. The instruction is conditional on the state of the request_type flag:

- request_type = Single

The DMAC performs a DMALD instruction and it sets arlen[3:0]=0x0 so that the AXI read transaction length is one. The DMAC ignores the value of the src_burst_len field in the channel control registers.

- request_type = Burst

The DMAC performs a DMANOP instruction. The DMAC increments the channel PC to the next instruction. No state change occurs.

[B] If B is present, the assembler sets bs to 1 and x to 1. The instruction is conditional on the state of the request_type flag:

- request_type = Single

The DMAC performs a DMANOP instruction. The DMAC increments the channel PC to the next instruction. No state change occurs.

- request_type = Burst

The DMAC performs a DMALD.

If you do not specify the S or B operand, the assembler sets bs to 0 and x to 0, and the DMAC always executes a DMA load.

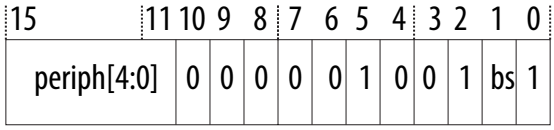
Operation

You can only use this instruction in a DMA channel thread. If you specify the S or B operand, execution of the instruction is conditional on the state of request_type matching that of the instruction.

DMALDP<S | B>

Load and notify Peripheral instructs the DMAC to perform a DMA load, using AXI transactions that source address registers and channel control registers specify. It places the read data into a FIFO buffer that is tagged with the corresponding channel number and after it receives the last data item, it sends an acknowledgement to the peripheral that the data transfer is complete. If the `src_inc` bit in the channel control registers is set to incrementing, the DMAC updates source address registers after it executes `DMALDP<S|B>`.

Figure 16-12: DMALDP<S|B> Instruction Encoding



Assembler syntax

`DMALDP<S|B> <peripheral>`

where:

`<S>` When S is present, the assembler sets `bs` to 0. The instruction is conditional on the state of the `request_type` flag:

- `request_type` = Single

The DMAC performs a `DMALDP` instruction and it sets `arlen[3:0]`=0x0 so that the AXI read transaction length is one. The DMAC ignores the value of the src_burst_len field in the channel control registers.

- `request_type` = Burst

The DMAC performs a `DMANOP`.

`<B>` When B is present, the assembler sets `bs` to 1. The instruction is conditional on the state of the `request_type` flag:

- `request_type` = Single

The DMAC performs a `DMANOP`.

- `request_type` = Burst

The DMAC performs a load using a burst DMA transfer.

`<peripheral>` 5-bit immediate, value 0-31.

Note: The DMAC sets the value of the `request_type` flag when it executes a `DMAWFP` instruction.

Operation

You can only use this instruction in a DMA channel thread. Execution of the instruction is conditional on the state of the `request_type` flag matching that of the instruction.

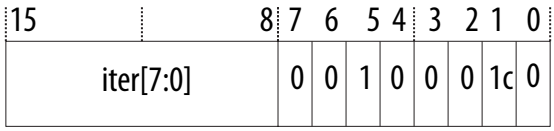
DMALP

Loop instructs the DMAC to load an 8-bit value into the loop counter register you specify.

This instruction indicates the start of a section of instructions, and you set the end of the section using the DMALPEND instruction. The DMAC repeats the set of instructions that you insert between DMALP and DMALPEND until the value in the loop counter register reaches zero.

Note: The DMAC saves the value of the PC for the instruction that follows DMALP. After the DMAC executes DMALPEND, and the loop counter register is not zero, this enables it to execute the first instruction in the loop.

Figure 16-13: DMALP Instruction Encoding



Assembler syntax

DMALP <loop_iterations>

where:

<loop_iterations>

Specifies the number of loops to perform, range 1-256.

- The assembler determines the loop counter register to use and either:
- Sets lc to 0, and the DMAC writes the value loop_iterations minus 1 to the loop counter 0 registers
- Sets lc to 1, and the DMAC writes the value loop_iterations minus 1 to the loop counter 1 registers.

Operation

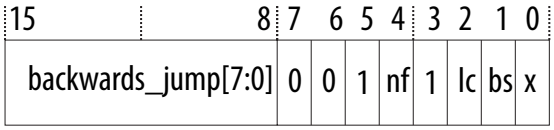
You can only use this instruction in a DMA channel thread.

DMALPEND[S | B]

Loop End indicates the last instruction in the program loop but the behavior of the DMAC depends on whether DMALP or DMALPFE starts the loop. If a loop starts with:

- DMALP The loop has a defined loop count and DMALPEND[S|B] instructs the DMAC to read the value of the loop counter register. If a loop counter register returns:
  - Zero—The DMAC executes a DMANOP and therefore exits the loop.
  - Nonzero—The DMAC decrements the value in the loop counter register and updates the thread PC to contain the address of the first instruction in the program loop, that is, the instruction that follows the DMALP.
- DMALPFE The loop has an undefined loop count and the DMAC uses the state of the request_last flag to control when it exits the loop. If the request_last flag is:
  - 0—The DMAC updates the thread PC to contain the address of the first instruction in the program loop, that is, the instruction that follows the DMALP.
  - 1—The DMAC executes a DMANOP and therefore exits the loop.

Figure 16-14: DMALPEND[S|B] Instruction Encoding



Assembler syntax

`DMALPEND[S|B]`

where:

`[S]` If S is present and the loop starts with `DMALP`, then the assembler sets `bs` to 0 and `x` to 1. The instruction is conditional on the state of the `request_type` flag:

- `request_type` = Single
  - The DMAC executes the `DMALPEND`
- `request_type` = Burst
  - The DMAC performs a `DMANOP` and therefore exits the loop.

`[B]` If B is present and the loop starts with `DMALP`, then the assembler sets `bs` to 1 and `x` to 1. The instruction is conditional on the state of the `request_type` flag:

- `request_type` = Single
  - The DMAC performs a `DMANOP` and therefore exits the loop.
- `request_type` = Burst
  - The DMAC executes the `DMALPEND`

If you do not specify the S or B operand, the assembler sets `bs` to 0 and `x` to 0, and the DMAC always executes the `DMALPEND`.

Note: You must not specify the S or B operand when a loop starts with `DMALPFE`. If you do, the assembler issues a warning message and sets `bs` to 0, `x` to 0, and `nf` to 1. In the same way as for `DMALPFE`, the DMAC uses the state of the `request_last` flag to control when it exits the loop.

Note: The DMAC sets the value of the:

- `request_type` flag when it executes a `DMAWFP` instruction.
- `request_last` flag to 1 when the corresponding peripheral issues the last request command through the peripheral request interface.

To correctly assign the additional bits in the `DMALPEND` instruction, the assembler determines the values for:

`backwards_jump[7:0]` Sets the relative location of the first instruction in the program loop. The assembler calculates the value for `backwards_jump[7:0]` by subtracting the address of the first instruction in the loop from the address of the `DMALPEND`.

- `nf` sets it to:
  - 0 if `DMALPFE` started the program loop
  - 1 if `DMALP` started the program loop.
- `lc` sets it to:
  - 0 if the loop counter 0 registers contains the loop counter value
  - 1 if the loop counter 1 registers contains the loop counter value
  - 1 if `DMALPFE` started the program loop.

Operation

You can only use this instruction in a DMA channel thread. If you specify the S or B operand, execution of the instruction is conditional on the state of the `request_type` flag matching that of the instruction.

Related Information

- **Peripheral Length Management** on page 16-12
- **DMAWFP** on page 16-42

DMALPFE

The assembler uses Loop Forever to configure certain bits in `DMALPEND`.

Note: When the assembler encounters `DMALPFE`, it does not create an instruction for the DMAC, but instead, it modifies the behavior of `DMALPEND`. The insertion of `DMALPFE` in program code identifies the start of the loop.

Assembler syntax

```
DMALPFE
```

Related Information

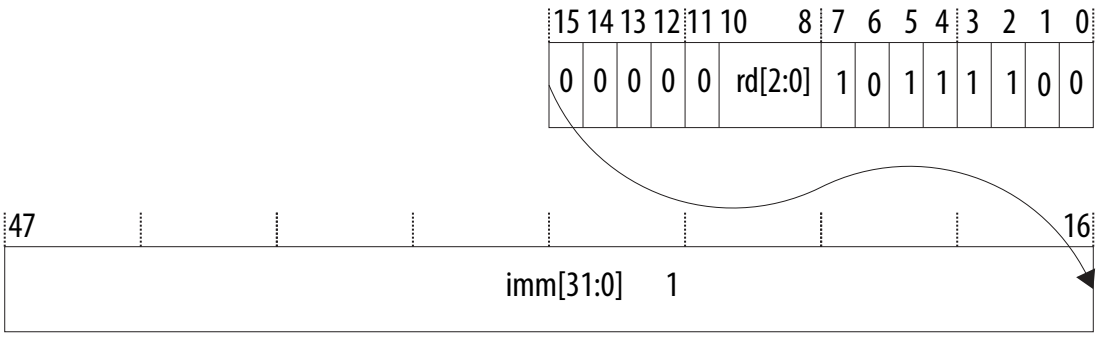
DMALPEND[S | B] on page 16-35

DMAMOV

Move instructs the DMAC to move a 32-bit immediate into the following registers:

- source address registers
- destination address registers
- channel control registers

Figure 16-15: DMAMOV Instruction Encoding



Assembler syntax

```
DMAMOV <destination_register>, <32- bit_immediate>
```

where:

`<destination_register>`

The valid registers are:

- `SAR`—selects the source address registers and sets `rd` to b000
- `CCR`—selects the channel control registers and sets `rd` to b001
- `DAR`—selects the destination address registers and sets `rd` to b010

`<32 -bit_immediate>`

A 32-bit value that is written to the specified destination register.

Note: For information about using the assembler to program the various fields that the channel control registers, refer to DMAMOV CCR section

Operation

You can only use this instruction in a DMA channel thread.

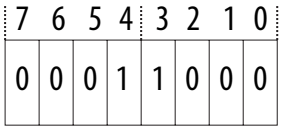
Related Information

DMAMOV CCR on page 16-44
Information about using the assembler to program the various fields that the channel control registers

DMANOP

No Operation does nothing. You can use this instruction for code alignment purposes.

Figure 16-16: DMANOP Instruction Encoding



Assembler syntax

```
DMANOP
```

Operation

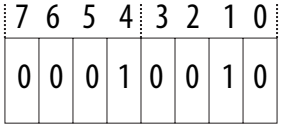
You can use the instruction with the DMA manager thread and the DMA channel thread.

DMARMB

Read Memory Barrier forces the DMA channel to wait until all of the executed `DMALD` instructions for that channel have been issued on the AXI master interface and have completed.

This enables write-after-read sequences to the same address location with no hazards.

Figure 16-17: DMARMB Instruction Encoding



Assembler syntax

```
DMARMB
```

Operation

You can only use this instruction in a DMA channel thread.

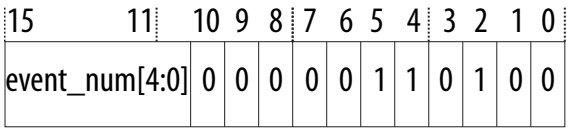
DMASEV

Send Event instructs the DMAC to modify an event-interrupt resource. Depending on how you program the interrupt enable register, this either:

- Generates event <event_num>

  Note: Typically, you use `DMAWFE` to stall a thread and then another thread executes `DMASEV`, using the appropriate event number, to unstall the waiting thread.
- Signals an interrupt using `irq <event_num>`.

Figure 16-18: DMASEV Instruction Encoding



Assembler syntax

```
DMASEV <event_num>
```

where:

`<event_num>` 5-bit immediate, value 0-31

Note: The DMAC aborts the thread if you select an event number that is not available.

Operation

You can use the instruction with the DMA manager thread and the DMA channel thread.

Related Information

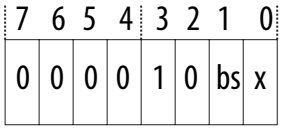
- **Using Events and Interrupts** on page 16-14
- **Using an Event to Restart DMA Channels** on page 16-15

DMAST[S | B]

Store instructs the DMAC to transfer data from the FIFO buffer to the location that the destination address registers specifies, using AXI transactions that the DA register and channel control registers

specify. If the dst_inc bit in the channel control registers is set to incrementing, the DMAC updates the destination address registers after it executes DMAST[S|B].

Figure 16-19: DMAST[S|B] Instruction Encoding



Assembler syntax

DMAST[S|B]

where:

[S] If S is present, the assembler sets bs to 0 and x to 1. The instruction is conditional on the state of the request_type flag:

- request_type = Single
- The DMAC performs a DMAST instruction and it sets awlen[3:0]=0x0 so that the AXI write transaction length is one. The DMAC ignores the v value of the dst_burst_len field in the channel control registers.
- request_type = Burst
- The DMAC performs a DMANOP instruction. The DMAC increments the channel PC to the next instruction. No state change occurs.

[B] If B is present, the assembler sets bs to 1 and x to 1. The instruction is conditional on the state of the request_type flag:

- request_type = Single
- The DMAC performs a DMANOP instruction. The DMAC increments the channel PC to the next instruction. No state change occurs.
- request_type = Burst
- The DMAC performs a DMAST.
- If you do not specify the S or B operand, the assembler sets bs to 0 and x to 0, and the DMAC always executes a DMA store.

Note: The DMAC sets the value of the request_type flag when it executes a DMAWFP instruction.

Operation

You can only use this instruction in a DMA channel thread. If you specify the S or B operand, execution of the instruction is conditional on the state of the request_type flag matching that of the instruction.

The DMAC only commences the burst when the MFIFO buffer contains all of the data necessary to complete the burst transfer.

Related Information

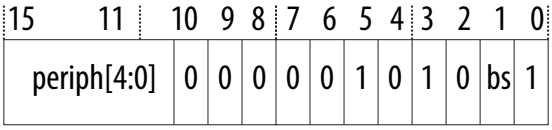
DMAWFP on page 16-42

DMASTP<S | B>

Store and notify Peripheral instructs the DMAC to transfer data from the FIFO buffer to the location that the destination address registers specifies, using AXI transactions that the DA register and channel control registers specify. It uses the DMA channel number to access the appropriate location in the FIFO

buffer. After the DMA store is complete, and the DMAC has received a buffered write response, it issues an acknowledgement to the peripheral that the data transfer is complete. If the dst_inc bit in the channel control registers is set to incrementing, the DMAC updates the destination address registers after it executes DMASTP<S|B>.

Figure 16-20: DMASTP<S|B> Instruction Encoding



Assembler syntax

DMASTP<S|B> <peripheral>

where:

<S> Sets bs to 0. This instructs the DMAC to perform:

- A single DMA store operation if request_type is programmed to Single
- The DMAC ignores the state of the dst_burst_len field in the channel control registers and always performs an AXI transfer with a burst length of one.
- A DMANOP if request_type is programmed to Burst.

<B> Sets bs to 1. This instructs the DMAC to perform:

- The DMA store if request_type is programmed to Burst
- A DMANOP if request_type is programmed to Single.

<peripheral> 5-bit immediate, value 0-31.

Note: The DMAC sets the value of the request_type flag when it executes a DMAWFP instruction.

Operation

You can only use this instruction in a DMA channel thread.

The DMAC only commences the burst when the MFIFO buffer contains all of the data necessary to complete the burst transfer.

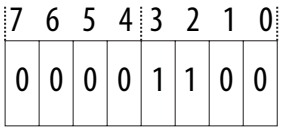
Related Information

DMAWFP on page 16-42

DMASTZ

Store Zero instructs the DMAC to store zeros, using AXI transactions that the destination address registers and channel control registers specify. If the dst_inc bit in the channel control registers is set to incrementing, the DMAC updates the destination address registers after it executes DMASTZ.

Figure 16-21: DMASTZ Instruction Encoding



Assembler syntax

```
DMASTZ
```

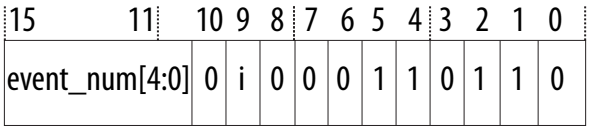
Operation

You can only use this instruction in a DMA channel thread.

DMAWFE

Wait For Event instructs the DMAC to halt execution of the thread until the event, that <event_num> specifies, occurs. When the event occurs, the thread moves to the Executing state and the DMAC clears the event.

Figure 16-22: DMAWFE Instruction Encoding



Assembler syntax

`DMAWFE <event_num>[, invalid]`

where:

`<event_num>` 5-bit immediate, value 0-31

`[invalid]` Sets `i` to 1. If `invalid` is present, the DMAC invalidates the instruction cache for the current DMA thread. If `invalid` is not present, then the assembler sets `i` to 0 and the DMAC does not invalidate the instruction cache for the current DMA.

- The DMAC aborts the thread if you select an event number that is not available for your configuration of the DMAC. To ensure cache coherency, you must use `invalid` when a processor writes the instruction stream for a DMA channel.

Operation

You can use the instruction with the DMA manager thread and the DMA channel thread.

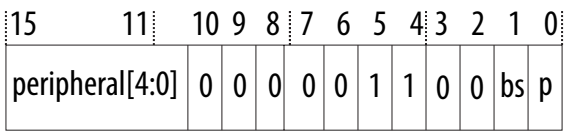
Related Information

Using Events and Interrupts on page 16-14

DMAWFP

Wait For Peripheral instructs the DMAC to halt execution of the thread until the specified peripheral signals a DMA request for that DMA channel.

Figure 16-23: DMAWFP Instruction Encoding



Assembler syntax

`DMAWFP <peripheral>, <single|burst|periph>`

where:

`<peripheral>` 5-bit immediate, value 0-31

Note: The DMAC aborts the thread if you select a peripheral number that is not available.

`<single>` Sets `bs` to 0 and `p` to 0. This instructs the DMAC to continue executing the DMA channel thread after it receives a single or burst DMA request. The DMAC sets the `request_type` to Single, for that DMA channel.

`<burst>` Sets `bs` to 1 and `p` to 0. This instructs the DMAC to continue executing the DMA channel thread after it receives a burst DMA request. The DMAC sets the `request_type` to Burst.

Note: The DMAC ignores single burst DMA requests.

`<periph>` Sets `bs` to 0 and `p` to 1. This instructs the DMAC to continue executing the DMA channel thread after it receives a single or burst DMA request. The DMAC sets the `request_type` to:

- **Single:** When it receives a single DMA request.
- **Burst:** When it receives a burst DMA request.

Operation

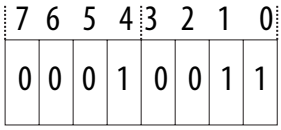
You can only use this instruction in a DMA channel thread.

DMAWMB

Write Memory Barrier forces the DMA channel to wait until all of the executed `DMAST` instructions for that channel have been issued on the AXI master interface and have completed.

This permits read-after-write sequences to the same address location with no hazards.

Figure 16-24: DMAWMB Instruction Encoding



Assembler syntax

`DMAWMB`

Operation

You can only use this instruction in a DMA channel thread.

Assembler Directives

The assembler provides several additional commands.

DCD

Assembler directive to place a 32-bit immediate in the instruction stream.

Syntax

DCD imm32

DCB

Assembler directive to place an 8-bit immediate in the instruction stream.

Syntax

DCB imm8

DMALP

Assembler directive to insert an iterative loop.

Syntax

DMALP [<LC0>|<LC1>] `<loop_iterations>`

where:

`<loop_iterations>`

An 8-bit value that specifies the number of loops to perform.

Note: For clarity in writing assembler instructions, the 8-bit value is the actual number of iterations of the loop to be executed. The assembler decrements this by one to create the actual value, 0-255, that the DMAC uses.

`[LC0]` If `LC0` is present, the DMAC stores `<loop_iterations>` in the loop counter 0 registers.

`[LC1]` If `LC1` is present, the DMAC stores `<loop_iterations>` in the loop counter 1 registers.

Note: If `LC0` or `LC1` is not present, the assembler determines the loop counter register to use.

DMALPFE

Assembler directive to insert a repetitive loop.

Syntax

DMALPFE

Enables the assembler to clear the `nf` bit that is present in `DMALPEND[S | B]`.

DMAMOV CCR

Assembler directive that enables you to program the channel control registers using the specified format.

Syntax

```
DMAMOV CCR,
[SB<1-16>] [SS<8|16|32|64|128>] [SA<I|F>]
[SP<imm3>] [SC<imm4>]
[DB<1-16>] [DS<8|16|32|64|128>] [DA<I|F>]
[DP<imm3>] [DC<imm4>]
[ES<8|16|32|64|128>]
```

Table 16-4: DMAMOV CCR Argument Description and Default Values

Syntax	Description	Options	Default
SA	Source address increment. Sets the value of `arburst[0]`	I = Increment F = Fixed	I
SS	Source burst size in bits. Sets the value of `arsize[2:0]`	8, 16, 32, or 64	8
SB	Source burst length. Sets the value of `arlen[3:0]`	1 to 16	1
SP	Source protection	0 to 7 (45)	0
SC	Source cache	0 to 15 (45)(46)	0
DA	Destination address increment. Sets the value of `awburst[0]`	I = Increment F = Fixed	I
DS	Destination burst size in bits. Sets the value of `awsize[2:0]`	8, 16, 32, or 64	8
DB	Destination burst length. Sets the value of `awlen[3:0]`	1 to 16	1
DP	Destination protection	0 to 7(45)	0
DC	Destination cache	0 to 15(45)(47)	0
ES	Endian swap size, in bits	8, 16, 32, or 64	8

MFIFO Buffer Usage Overview

About MFIFO Buffer Usage Overview

The MFIFO buffer is a shared resource that is utilized on a first-come, first-served basis by all currently active channels. To a program, it appears as a set of variable-depth parallel FIFO buffers, one per channel, with the restriction that the total depth of all the FIFOs cannot exceed the size of the MFIFO, which is 512 entries. The width of the AXI master interface is the same as the MFIFO buffer width.

The DMAC is capable of realigning data from the source to the destination. For example, the DMAC shifts the data by two byte lanes when it reads a word from address 0x103 and writes to address 0x205. All byte manipulations occur when data enters the MFIFO buffer, as a result of an AXI read due to a `DMALD`

(45) You must use decimal values when programming this immediate value.
(46) Because the DMAC ties ARCACHE[3] low, the assembler always sets bit 3 to 0 and uses bits [2:0] of your chosen value for SC.
(47) Because the DMAC ties AWCACHE[2] low, the assembler always sets bit 2 to 0 and uses bit [3] and bits [1:0] of your chosen value for DC.

instruction, so that the DMAC does not need to manipulate the data when it removes it from the MFIFO buffer, as a result of an AXI write due to a DMAST instruction. Therefore the storage and packing of the data in the MFIFO buffer is determined by the destination address and transfer characteristics.

When a program specifies that incrementing transactions are to be performed to the destination, the DMAC packs data into the MFIFO buffer to minimize the usage of the MFIFO buffer entries. For example, the DMAC packs two 32-bit words into a single entry in the MFIFO buffer when the program uses a source address of 0x100, and destination address of 0x200.

The number of entries required to store the data loaded from a source is not a simple calculation of amount of source data divided by MFIFO buffer width in the following situations:

- The source address is not aligned to the AXI bus width.
- The destination address is not aligned to the AXI bus width.
- The transactions are to a fixed destination, that is, a non-incrementing address.

The DMALD and DMAST instructions each specify that an AXI transaction is to be performed. The amount of data transferred by an AXI transaction depends on the values programmed in to the CCR *n* register and the address of the transaction.

The following sections provide several example DMAC programs together with illustrations of the MFIFO buffer usage.

Note: These sections show MFIFO buffer usage in the following ways:

- A graph of the number of MFIFO buffer entries versus time
- A diagram of the byte-lane manipulation that the DMAC performs when data enters the MFIFO buffer.

Note: The numbers 0 and 7 in the MFIFO buffer diagrams indicate the byte lanes in the MFIFO buffer.

Aligned Transfers

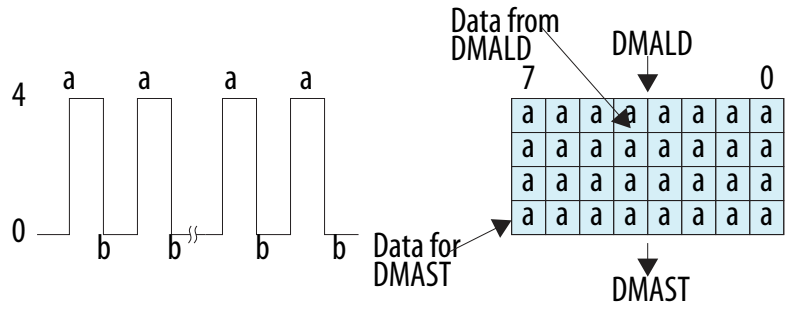
Simple Aligned Program

The following program shows the MFIFO buffer usage. In this program, the source address and destination address are aligned with the AXI data bus width.

```
DMAMOV CCR, SB4 SS64 DB4 DS64
DMAMOV SAR, 0x1000
DMAMOV DAR, 0x4000
DMALP 16
    DMALD    ; shown as a in figure below
               DMAST    ; shown as b in figure below
DMALPEND
DMAEND
```

Figure 16-25: Simple Aligned Program

Each DMALD requires four entries and each DMAST removes four entries.



This example has a static requirement of zero MFIFO buffer entries and a dynamic requirement of four MFIFO buffer entries.

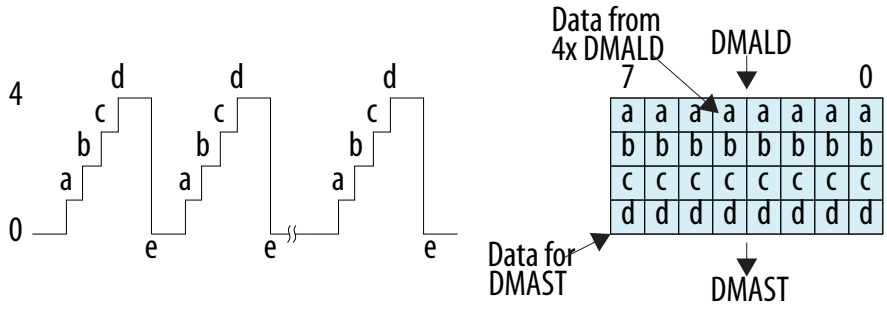
Aligned Asymmetric Program with Multiple Loads

The following program performs four loads for each store and the source address and destination address are aligned with the AXI data bus width.

```
DMAMOV CCR, SB1 SS64 DB4 DS64
DMAMOV SAR, 0x1000
DMAMOV DAR, 0x4000
DMALP 16
    DMALD    ; shown as a in the figure below
    DMALD ; shown as b in the figure below
    DMALD ; shown as c in the figure below
    DMALD ; shown as d in the figure below
    DMAST ; shown as e in the figure below
DMALPEND
DMAEND
```

Figure 16-26: Aligned Asymmetric Program with Multiple Loads

Each DMALD requires one entry and each DMAST removes four entries.



This example has a static requirement of zero MFIFO buffer entries and a dynamic requirement of four MFIFO buffer entries.

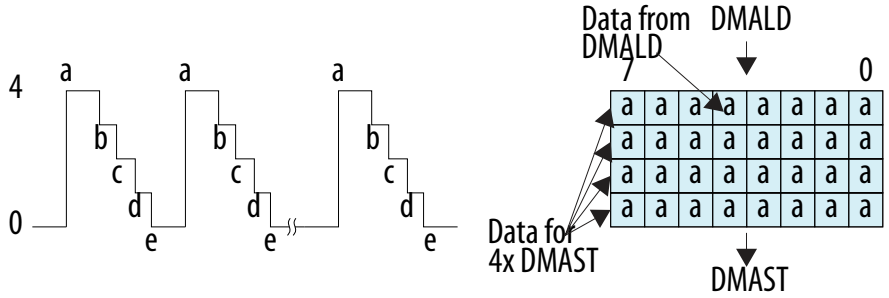
Aligned Asymmetric Program with Multiple Stores

The following program performs four stores for each load and the source address and destination address are aligned with the AXI data bus width.

```
DMAMOV CCR, SB4 SS64 DB1 DS64
DMAMOV SAR, 0x1000
DMAMOV DAR, 0x4000
DMALP 16
    DMALD ; shown as a in the figure below
    DMAST ; shown as b in the figure below
    DMAST ; shown as c in the figure below
    DMAST ; shown as d in the figure below
    DMAST ; shown as e in the figure below
DMALPEND
DMAEND
```

Figure 16-27: Aligned Asymmetric Program with Multiple Stores

Each DMALD requires four entries and each DMAST removes one entry.



This example has a static requirement of zero MFIFO buffer entries and a dynamic requirement of four MFIFO buffer entries.

Unaligned Transfers

Aligned Source Address to Unaligned Destination Address

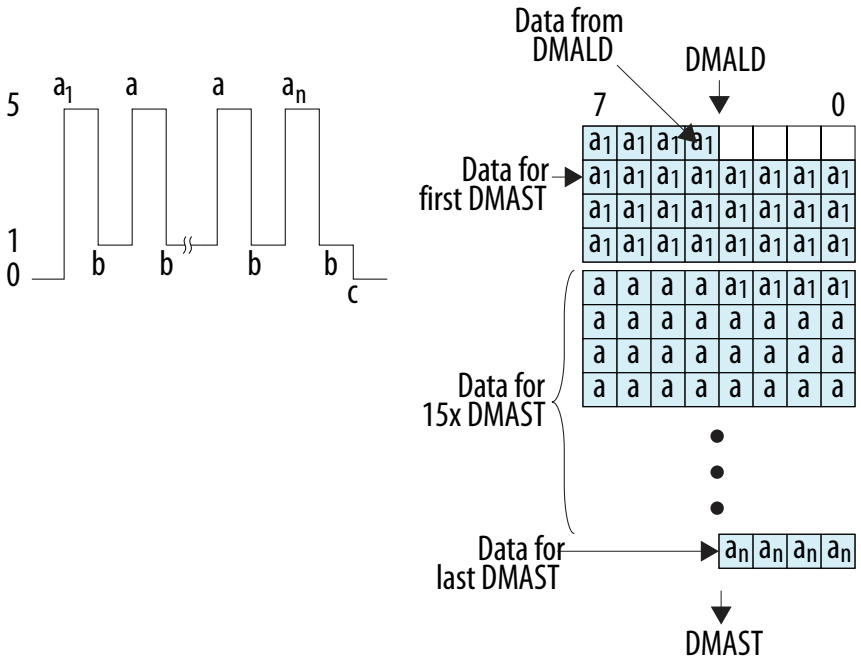
In the following program, the source address is aligned with the AXI data bus width but the destination address is unaligned. The destination address is not aligned to the destination burst size so the first DMAST instruction removes less data than the first DMALD instruction reads. Therefore, a final DMAST of a single word is required to clear the data from the MFIFO buffer.

```
DMAMOV CCR, SB4 SS64 DB4 DS64
DMAMOV SAR, 0x1000
DMAMOV DAR, 0x4004
DMALP 16
    DMALD ; shown as a1, ... a, an in the figure below
    DMAST ; shown as b in the figure below
DMALPEND
DMAMOV CCR, SB4 SS64 DB1 DS32
DMAST ; shown as c in the figure below
DMAEND
```

Figure 16-28: Aligned to Unaligned Program

The first DMALD instruction loads four doublewords but because the destination address is unaligned, the DMAC shifts them by four bytes and therefore uses five entries in the MFIFO buffer.

Each DMAST requires only four entries of data, and therefore the extra entry remains in use for the duration of the program, until it is emptied by the last DMAST.



This example has a static requirement of one MFIFO buffer entry and a dynamic requirement of four MFIFO buffer entries.

Unaligned Source Address to Aligned Destination Address

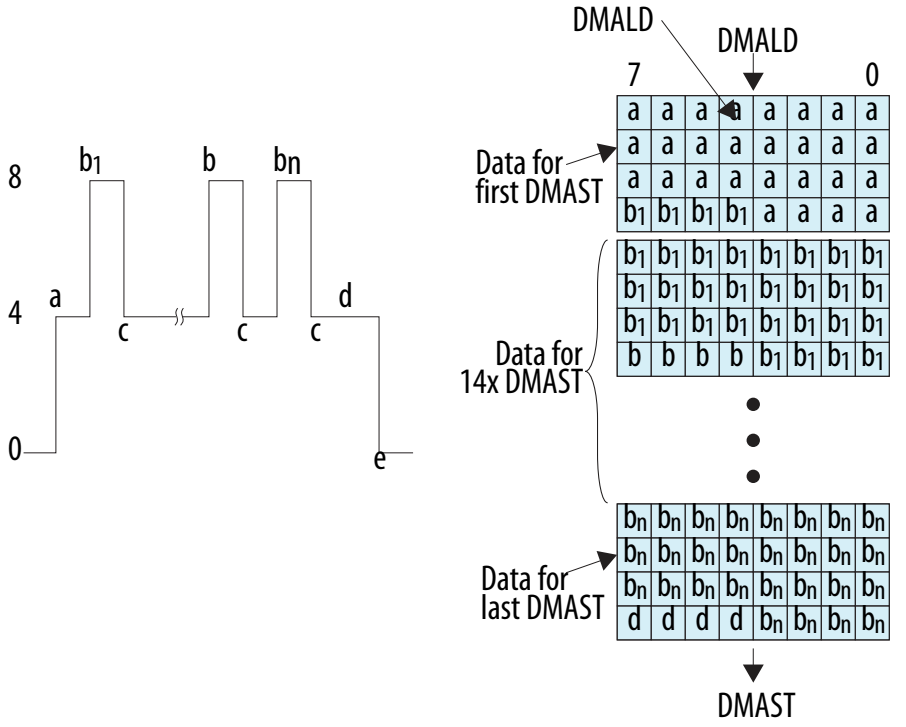
In this program, the source address is unaligned with the AXI data bus width but the destination address is aligned. The source address is not aligned to the source burst size so the first DMALD instruction reads in less data than the DMAST. Therefore, an extra DMALD is required to satisfy the first DMAST.

```
DMAMOV CCR, SB4 SS64 DB4 DS64
DMAMOV SAR, 0x1004
DMAMOV DAR, 0x4000
DMALD ; shown as a in the figure below
DMALP 15
    DMALD ; shown as b1, ... b, bn in the figure below
    DMAST ; shown as c in the figure below
DMALPEND
DMAMOV CCR, SB1 SS32 DB4 DS64
DMALD ; shown as d in the figure below
DMAST ; shown as e in the figure below
DMAEND
```

Figure 16-29: Unaligned to Aligned Program

The first DMALD instruction does not load sufficient data to enable the DMAC to execute a DMAST and therefore the program includes an additional DMALD, prior to the start of the loop.

After the first DMALD, the subsequent DMALDs align with the source burst size. This optimizes the **b** performance but it requires a larger number of MFIFO buffer entries.



Note: The DMALD shown as **d** does not increase the MFIFO buffer usage because it loads four bytes into an MFIFO buffer entry that the DMAC has already allocated to this channel.

This example has a static requirement of four MFIFO buffer entries and a dynamic requirement of four MFIFO buffer entries.

Unaligned Source Address to Aligned Destination Address with Excess Initial Load

This program is an alternative to that described in *Unaligned Source Address to Aligned Destination Address*. The program executes a different sequence of source bursts that might be less efficient, but requires fewer MFIFO buffer entries.

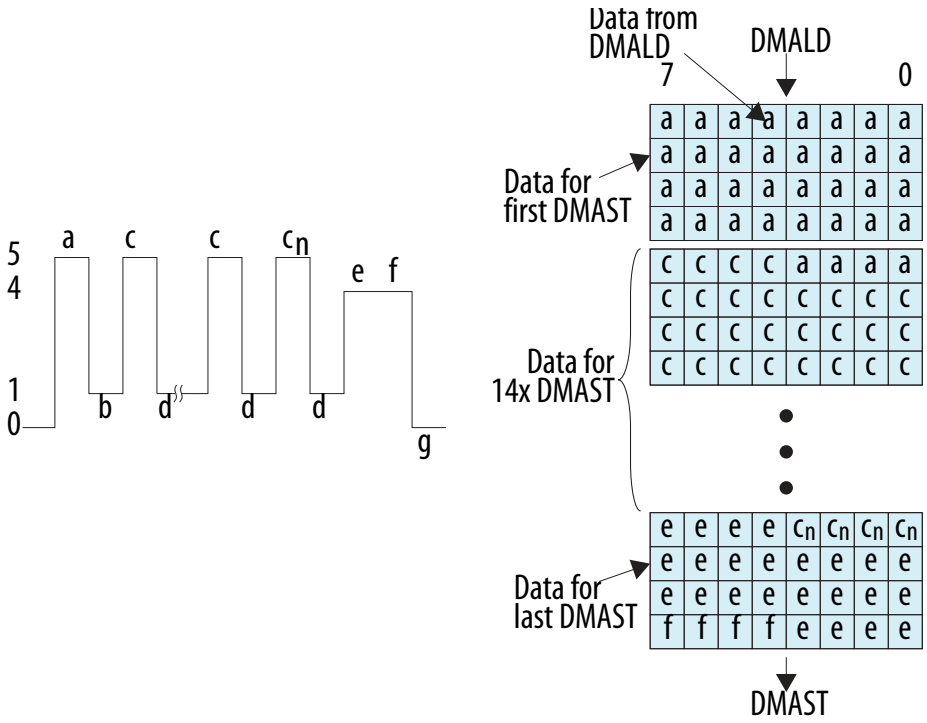
```
DMAMOV CCR, SB5 SS64 DB4 DS64
DMAMOV SAR, 0x1004
DMAMOV DAR, 0x4000
DMALD ; shown as a in the figure below
DMAST ; shown as b in the figure below
DMAMOV CCR, SB4 SS64 DB4 DS64
DMALP 14
    DMALD ; shown as c and cn in the figure below
                DMAST ; shown as d in the figure below
DMALPEND
DMAMOV CCR, SB3 SS64 DB4 DS64
DMALD ; shown as e in the figure below
```

```
DMAMOV CCR, SB1 SS32 DB4 DS64
DMALD ; shown as f in the figure below
DMAST ; shown as g in the figure below
DMAEND
```

Figure 16-30: Unaligned to Aligned with Excess Initial Load

The first DMALD instruction loads five bursts of data to enable the DMAC to execute the first DMAST.

After the first DMALD, the subsequent DMALDs are not aligned to the source burst size, for example the second DMALD reads from address 0x1028. After the loop, the final two DMALDs read the data required to satisfy the final DMAST.



Note: The DMALD shown as **f** does not increase the MFIFO buffer usage because it loads four bytes into an MFIFO buffer entry that the DMAC has already allocated to this channel.

This example has a static requirement of one MFIFO buffer entry and a dynamic requirement of four MFIFO buffer entries.

Related Information

Unaligned Source Address to Aligned Destination Address on page 16-49

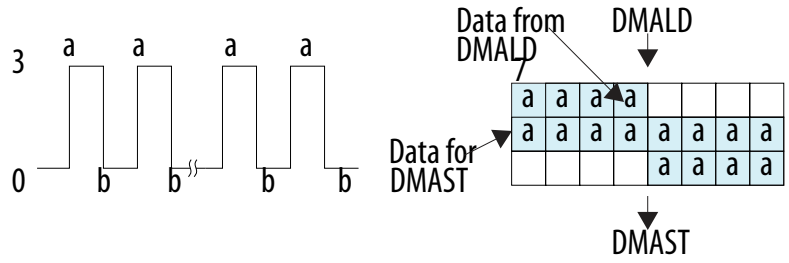
Aligned Burst Size Unaligned MFIFO Buffer

In this program, the destination address, which is narrower than the MFIFO buffer width, aligns with the burst size, but does not align with the MFIFO buffer width.

```
DMAMOV CCR, SB4 SS32 DB4 DS32
DMAMOV SAR, 0x1000
DMAMOV DAR, 0x4004
DMALP 16
```

```
 DMALD ; shown as a in the figure below
 DMAST ; shown as b in the figure below
DMALPEND
DMAEND
```

Figure 16-31: Aligned Burst with Unaligned MFIFO Buffer Width



In this example, the destination address is not 64-bit aligned, it requires three rather than the expected two MFIFO buffer entries.

This example has a static requirement of zero MFIFO buffer entries and a dynamic requirement of three MFIFO buffer entries.

Fixed Transfers

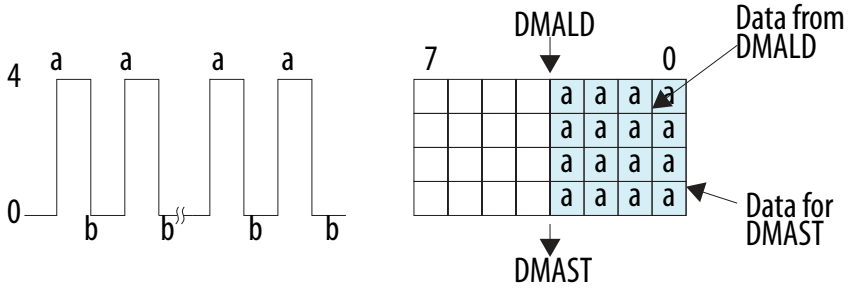
Fixed Destination with Aligned Address

In this program, the source address and destination address are aligned with the AXI data bus width, and the destination address is fixed.

```
DMAMOV CCR, SB2 SS64 DB4 DS32 DAF
DMAMOV SAR, 0x1000
DMAMOV DAR, 0x4000
DMALP 16
    DMALD ; shown as a in the figure below
    DMAST ; shown as b in the figure below
DMALPEND
DMAEND
```

Figure 16-32: Fixed Destination with Aligned Address

Each `DMALD` in the program loads two 64-bit data transfers into the MFIFO buffer. Because the destination address is a 32-bit fixed address, then the DMAC splits each 64-bit data item across two entries in the MFIFO buffer.

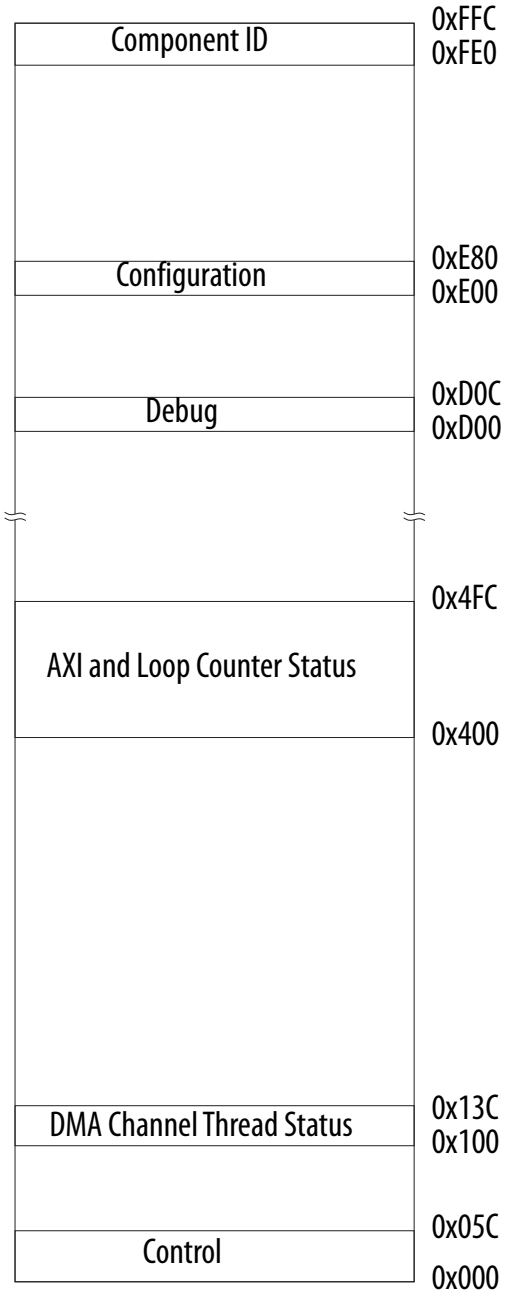


This example has a static requirement of zero MFIFO buffer entries and a dynamic requirement of four MFIFO buffer entries.

DMA Controller Registers

The following DMAC register map spans a 4 KB region, consists of the following sections.

Figure 16-33: DMAC Summary Register Map



- **Control registers—** allow you to control the DMAC.
- **DMA channel thread status registers—**provide the status of the DMA channel threads.
- **AXI and loop counter status registers—**provide the AXI transfer status and the loop counter status for each DMA channel thread.
- **Debug registers—**enable the following functionality:
  - Allow you to send instructions to a thread when debugging the program code.
  - Allow system firmware to send instructions to the DMA manager thread.
- **Configuration registers—**enable system firmware to identify the configuration of the DMAC and control the behavior of the watchdog.
- **Component ID registers—** enable system firmware to identify peripherals. Do not attempt to access reserved or unused address locations. Attempting to access these locations can result in an unpredictable behavior.

Ethernet Media Access Controller 17

2014.12.15

av_5v4

The hard processor system (HPS) provides two Ethernet media access controller (EMAC) peripherals. Each EMAC can be used to transmit and receive data at 10/100/1000 Mbps over Ethernet connections in compliance with the IEEE 802.3 specification. The EMACs are instances of the Synopsys DesignWare 3504-0 Universal 10/100/1000 Ethernet MAC (DWC_gmac).

The EMAC has an extensive memory-mapped control and status register (CSR) set, which can be accessed by the ARM Cortex-A9® MPCore.

For an understanding of this chapter, you should be familiar with the basics of IEEE 802.3 media access control (MAC). [48]

Features of the Ethernet MAC

MAC

- IEEE 802.3-2008 compliant
- Data rates of 10/100/1000 Mbps
- Full duplex and half duplex modes
  - IEEE 802.3x flow control automatic transmission of zero-quanta pause frame on flow control input deassertion
  - Optional forwarding of received pause control frames to the user
  - Packet bursting and frame extension in 1000 Mbps half-duplex
  - IEEE 802.3x flow control in full-duplex
  - Back-pressure support for half-duplex
- 4 KB TX FIFO RAM and 4 KB RX FIFO RAM with ECC support
- IEEE 1588-2002 and IEEE 1588-2008 precision networked clock synchronization
- IEEE 802.3-az, version D2.0 for Energy Efficient Ethernet (EEE)
- IEEE 802.1Q virtual local area network (VLAN) tag detection for reception frames
- Preamble and start-of-frame data (SFD) insertion in transmit and deletion in receive paths
- Automatic cyclic redundancy check (CRC) and pad generation controllable on a per-frame basis
- Options for automatic pad/CRC stripping on receive frames
- Programmable frame length supporting standard and jumbo Ethernet frames (with size up to 9.6 KB)
- Programmable inter-frame gap (IFG), from 40- to 96-bit times in steps of eight
- Preamble of up to 1 byte supported
- Supports internal loopback asynchronous FIFO on the GMII/MII for debugging
- Supports a variety of flexible address filtering modes
  - Up to 31 additional 48-bit perfect destination address (DA) filters with masks for each byte
  - Up to 31 48-bit source address (SA) comparison check with masks for each byte
  - 256-bit hash filter (optional) for multicast and unicast DAs
  - Option to pass all multicast addressed frames
  - Promiscuous mode support to pass all frames without any filtering for network monitoring
  - Passes all incoming packets (as per filter) with a status report

DMA

- 32-bit interface
- Programmable burst size for optimal bus utilization
- Single-channel mode transmit and receive engines
- Byte-aligned addressing mode for data buffer support
- Dual-buffer (ring) or linked-list (chained) descriptor chaining
- Descriptors can each transfer up to 8 KB of data
- Independent DMA arbitration for transmit and receive with fixed priority or round robin

Management Interface

- 32-bit host interface to CSR set
- Comprehensive status reporting for normal operation and transfers with errors
- Configurable interrupt options for different operational conditions
- Per-frame transmit/receive complete interrupt control
- Separate status returned for transmission and reception packets

Acceleration

Transmit and receive checksum offload for transmission control protocol (TCP), user datagram protocol (UDP), or Internet control message protocol (ICMP) over Internet protocol (IP)

PHY Interface

Different external PHY interfaces are provided depending on whether the Ethernet Controller signals are routed through the HPS I/O pins or the FPGA I/O pins.

The PHY interfaces supported using the HPS I/O pins are:

- Reduced Gigabit Media Independent Interface (RGMII)

The PHY interfaces supported using adaptor logic to route signals to the FPGA I/O pins are:

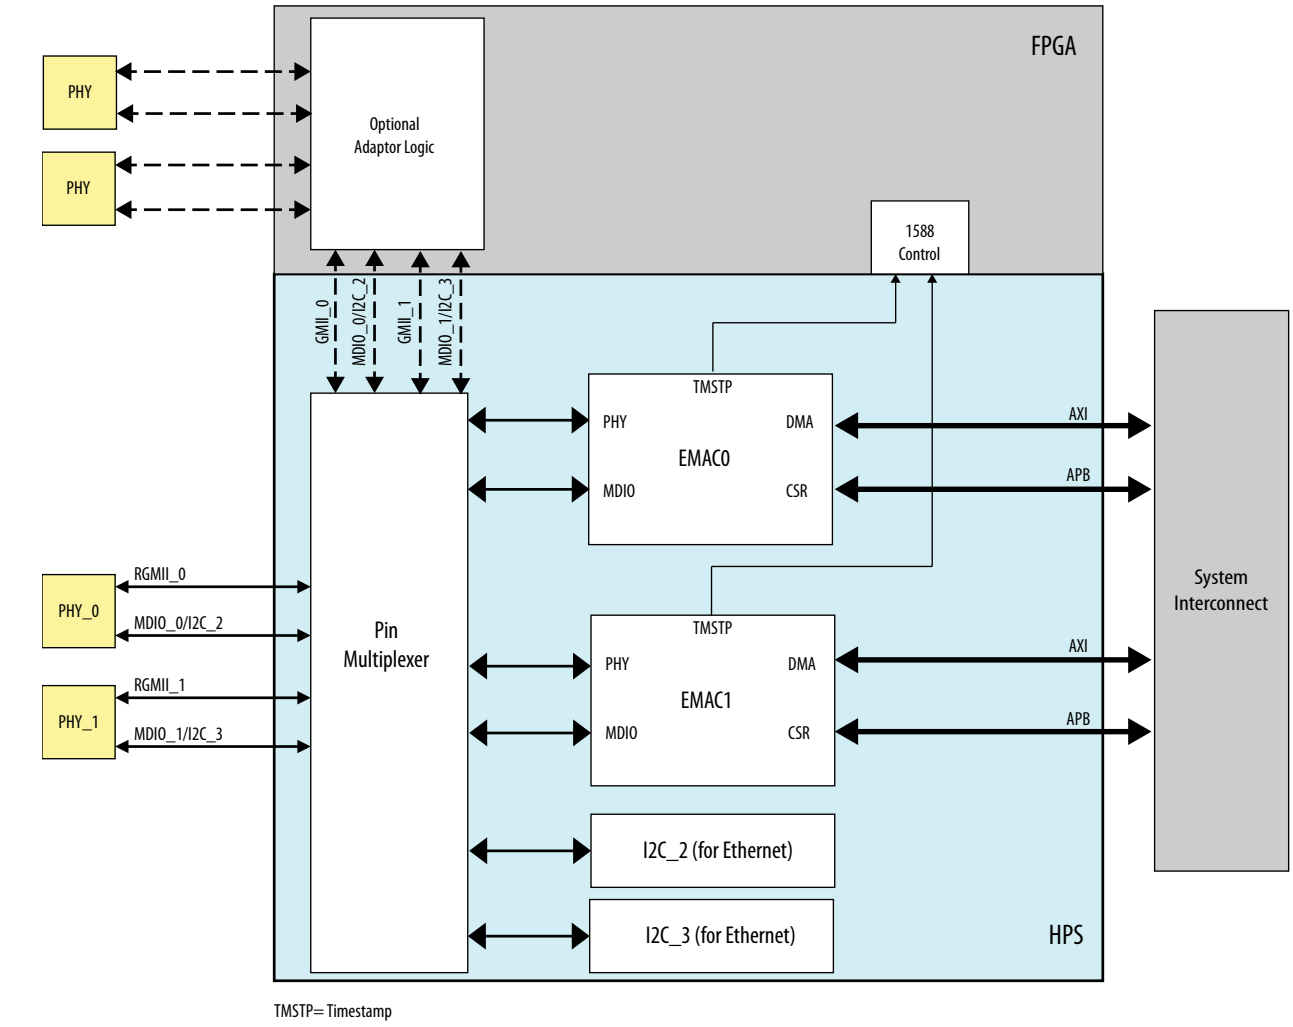
- Media Independent Interface (MII)
- Gigabit Media Independent Interface (GMII)
- Reduced Media Independent Interface (RMII)
- Reduced Gigabit Media Independent Interface (RGMII)
- Serial Gigabit Media Independent Interface (SGMII) supported through the GMII to FPGA fabric with additional external conversion logic

The Ethernet Controller has two choices for the management control interface used for configuration and status monitoring of the PHY:

- Management Data Input/Output (MDIO)
- I^2C PHY management through a separate I^2C module within the HPS

EMAC Block Diagram and System Integration

Figure 17-1: EMAC System Integration



The EMACs are integrated into the HPS portion of the system on a chip (SoC) device. They communicate with the I/O pins.

EMAC Signal Descriptions

The EMAC provides a variety of PHY interfaces and control options through the HPS and the FPGA I/Os.

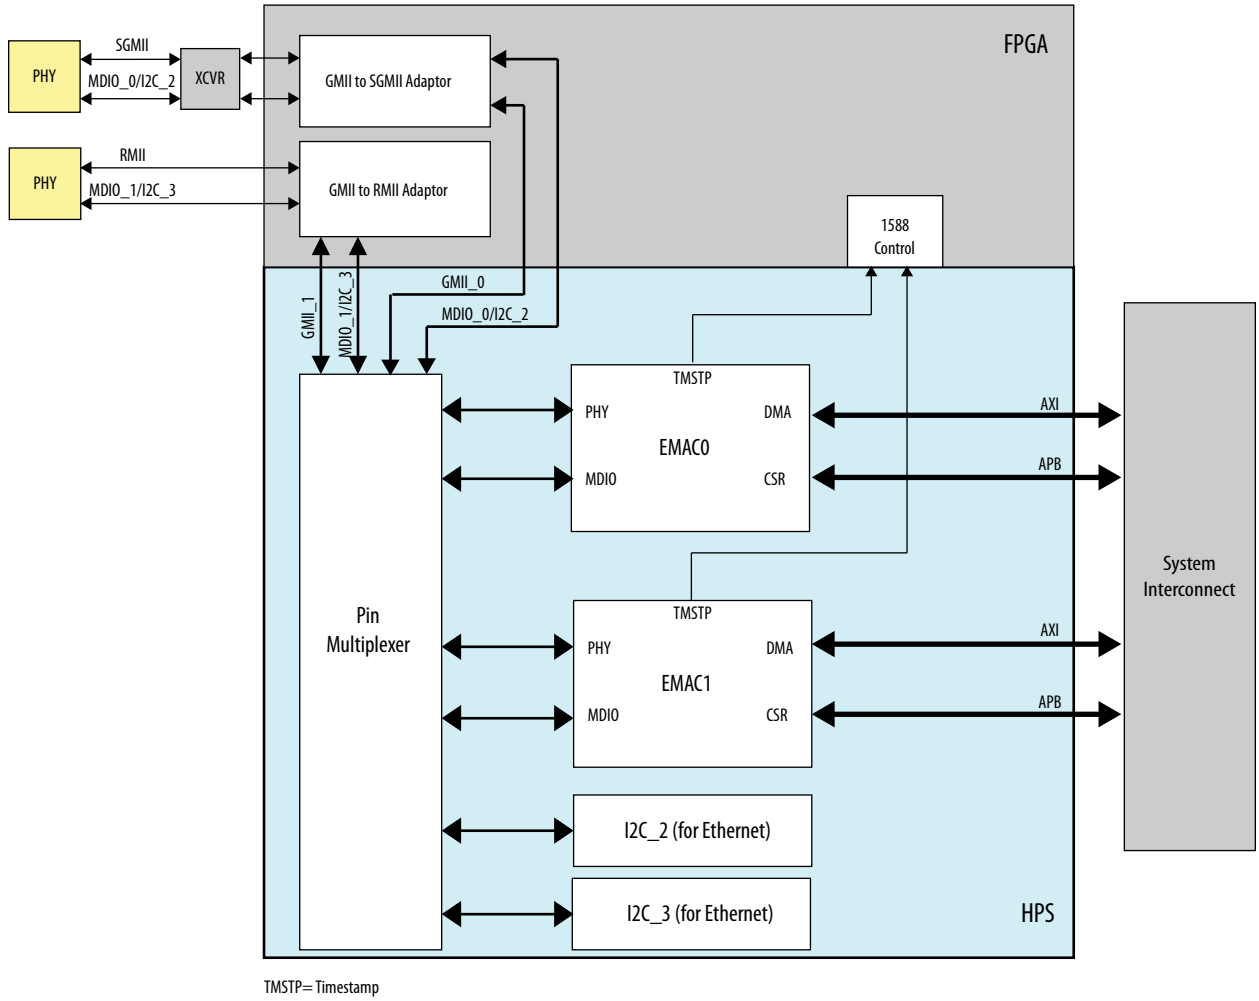
For designs in which the HPS is pin-limited, the EMAC signals can be routed through the FPGA as any one of the following interfaces by using soft adaptor logic in the FPGA:

- RMII/RGMII
- MII/GMII
- SGMII with some additional external logic

The figure below depicts a design which routes the EMAC0 and EMAC1 signals through the FPGA to provide an RMII and SGMII interface.

Refer to the *Ethernet MAC Programming Model* section to find out more information about configuring EMAC interfaces through FPGA.

Figure 17-2: EMAC to FPGA Routing Example



Note: The Micrel KSZ9021RN Ethernet PHY has been verified to work properly with the HPS EMAC and is recommended for use in board design.

HPS EMAC I/O Signals

The following table lists the EMAC signals that are routed to the HPS pins. These signals provide the RGMII interface.

Table 17-1: HPS EMAC I/O Signals

EMAC Port		In/Out	Width	Description
clk_tx_i	Transmit Clock	Out	1	This signal provides the transmit clock for RGMII (125/25/2.5 MHz in 1G/100M/10Mbps) and RMII (50 MHz in 100M / 10 Mbps). All PHY transmit signals generated by the EMAC are synchronous to this clock.
phy_txd_o	PHY Transmit Data	Out	8	This group of eight transmit data signals is driven by the MAC. Bits [3:0] provide the RGMII transmit data, and bits [1:0] provide the RMII transmit data. Unused bits in the RGMII and RMII interface configuration are tied low. In RGMII mode, the data bus carries transmit data at double rate and are sampled on both the rising and falling edges of the transmit clock. The validity of the data is qualified with phy_txen_o.
phy_txen_o	PHY Transmit Data Enable	Out	1	This signal is driven by the EMAC component, and in RGMII mode acts as the control signal (rgmii_tctl) for the transmit data, and is driven on both edges of the transmit clock, phy_txclk_o.
phy_clk_rx_i	Receive Clock	In	1	In RGMII mode, this clock frequency is 125/25/2.5 MHz in 1 G/100 M/10 Mbps modes. It is provided by the external PHY. All PHY signals received by the EMAC are synchronous to this clock.
phy_rxd_i	PHY Receive Data	In	8	These eight data signals are received from the PHY and carry receive data at double rate with bits[3:0] valid on the rising edge of phy_rxclk_i, and bits[7:4] valid on the falling edge of phy_rxclk_i. The validity of the data is qualified with phy_rxdv_i.

EMAC Port		In/Out	Width	Description
phy_rxdv_i	PHY Receive Data Valid	In	1	This signal is driven by PHY and functions are the receive control signal used to qualify the data received on phy_rxd_i. This signal is sampled on both edges of the clock.

FPGA EMAC I/O Signals

Table 17-2: FPGA EMAC I/O Signals

Signal Name		In/Out	Width	Description
phy_clk_tx_i	Transmit Clock	In	1	This is the transmit clock (2.5 MHz/25 MHz) provided by the MII PHYs only. This clock comes from the FPGA Interface and is used for TX data capture. This clock is not used in GMII mode. **Note:** This clock must be able to perform glitch free switching between 2.5 and 25 MHz.
phy_txclk_o	Transmit Clock Output	Out	1	In GMII mode, this signal is the transmit clock output to the PHY to sample data. For MII, this clock is unused.
phy_txd_o	PHY Transmit Data	Out	8	These are a group of eight transmit data signals driven by the EMAC. All eight bits provide the GMII transmit data byte. For the lower speed MII operation, only the bits[3:0] are used. The validity of the data is qualified with phy_txen_o and phy_txer_o. Synchronous to phy_txclk_o.
phy_txen_o	PHY Transmit Data Enable	Out	1	This signal is driven by the EMAC and is used in GMII mode. When driven high, this signal indicates that valid data is being transmitted on the clk_tx_o bus.

Signal Name		In/Out	Width	Description
phy_txer_o	PHY Transmit Error	Out	1	This signal is driven by the EMAC and when high, indicates a transmit error or carrier extension on the phy_txd bus. It is also used to signal low power states in Energy Efficient Ethernet operation.
rst_clk_tx_n_o	Transmit Clock Reset output	Out	1	Transmit clock reset output to the FPGA fabric, which is the internal synchronized reset to clk_tx_int output from the EMAC. May be used by logic implemented in the FPGA fabric as desired.
phy_clk_rx_i	Receive Clock	In	1	Receive clock from external PHY. For GMII, the clock frequency is 125 MHz. For MII, the receive clock is 25 MHz for 100 Mbps and 2.5 MHz for 10 Mpbs.
phy_rxd_i	PHY Receive Data	In	8	This is an eight-bit receive data bus from the PHY. In GMII mode, all eight bits are driven. The validity of the data is qualified with phy_rxdv_i and phy_rxer_i. For lower speed MII operation, only bits [3:0] are driven. These signals are synchronous to phy_clk_rx_i.
phy_rxdv_i	PHY Receive Data Valid	In	1	This signal is driven by PHY. In GMII mode, when driven high, it indicates that the data on the phy_rxd bus is valid. It remains asserted continuously from the first recovered byte of the frame through the final recovered byte.
phy_rxer_i	PHY Receive Error	In	1	This signal indicates an error or carrier extension (GMII) in the received frame. This signal is synchronous to phy_clk_rx_i and is not used in RGMII mode.
rst_clk_rx_n_o	Receive clock reset output.	Out	1	Receive clock reset output.

Signal Name		In/Out	Width	Description
phy_crs_i	PHY Carrier Sense	In	1	This signal is asserted by the PHY when either the transmit or receive medium is not idle. The PHY de-asserts this signal when both transmit and receive interfaces are idle. This signal is not synchronous to any clock.
phy_col_i	PHY Collision Detect	In	1	This signal, valid only when operating in half duplex, is asserted by the PHY when a collision is detected on the medium. This signal is not synchronous to any clock.

Related Information

EMAC FPGA Interface Initialization on page 17-59
Information on how to initialize GMII/MII interface

PHY Management Interface

The HPS can provide support for either MDIO or I^2C PHY management interfaces.

MDIO Interface

The MDIO interface signals are synchronous to `l4_mp_clk` in all supported modes.

Note: Both the HPS and FPGA support MDIO interface I/O.

Table 17-3: PHY MDIO Management Interface

Signal	In/Out	Width	Description
gmii_mdi_i	In	1	Management Data In. The PHY generates this signal to transfer register data during a read operation. This signal is driven synchronously with the gmii_mdc_o clock.
gmii_mdo_o	Out	1	Management Data Out. The EMAC uses this signal to transfer control and data information to the PHY.
gmii_mdo_o_e	Out	1	Management Data Output Enable. This enable signal drives the gmii_mdo_o signal from an external three-state I/O buffer. This signal is asserted whenever valid data is driven on the gmii_mdo_o signal. The active state of this signal is high.

Signal	In/Out	Width	Description
gmii_mdc_o	Out	1	Management Data Clock. The EMAC provides timing reference for the gmii_mdi_i and gmii_mdo_o signals on MII through this aperiodic clock. The maximum frequency of this clock is 2.5 MHz. This clock is generated from the application clock through a clock divider.

I²C External PHY Management Interface

Some PHY devices use the I²C instead of MDIO for their control interface. Small form factor pluggable (SFP) optical or pluggable modules are often among those with this interface.

The HPS or FPGA can use two of the four general purpose I²C peripherals for controlling the PHY devices:

- I2C2 at base address 0xFFC06000
- I2C3 at base address 0xFFC07000

EMAC Internal Interfaces

DMA Master Interface

The DMA interface acts as a bus master on the system interconnect. Two types of data are transferred on the interface: data descriptors and actual data packets. The interface is very efficient in transferring full duplex Ethernet packet traffic. Read and write data transfers from different DMA channels can be performed simultaneously on this port, except for transmit descriptor reads and write-backs, which cannot happen simultaneously.

DMA transfers are split into a software configurable number of burst transactions on the interface. The AXI_Bus_Mode register in the dmagrp group is used to configure bursting behavior.

The interface assigns a unique ID for each DMA channel and also for each read DMA or write DMA request in a channel. Data transfers with distinct IDs can be reordered and interleaved.

The DMA interface can be configured to perform cacheable accesses. This configuration can be done in the System Manager when the DMA interface is inactive.

Write data transfers are generally performed as posted writes with OK responses returned as soon as the system interconnect has accepted the last beat of a data burst. Descriptors (status or timestamp), however, are always transferred as non-posted writes in order to prevent race conditions with the transfer complete interrupt logic.

The slave may issue an error response. When that happens, the EMAC disables the DMA channel that generated the original request and asserts an interrupt signal. The host must reset the EMAC with a hard or soft reset to restart the DMA to recover from this condition.

The EMAC supports up to 16 outstanding transactions on the interface. Buffering outstanding transactions smooths out back pressure behavior improving throughput when resource contention bottlenecks arise under high system load conditions.

Timestamp Interface

The timestamp clock reference can come from either the Clock Manager or the FPGA fabric. If the FPGA has implemented the serial capturing of the timestamp interface, then the FPGA must provide the PTP clock reference.

In addition to providing a timestamp clock reference, the FPGA can monitor the pulse-per-second output from each EMAC module and trigger a snapshot from each auxiliary time stamp timer.

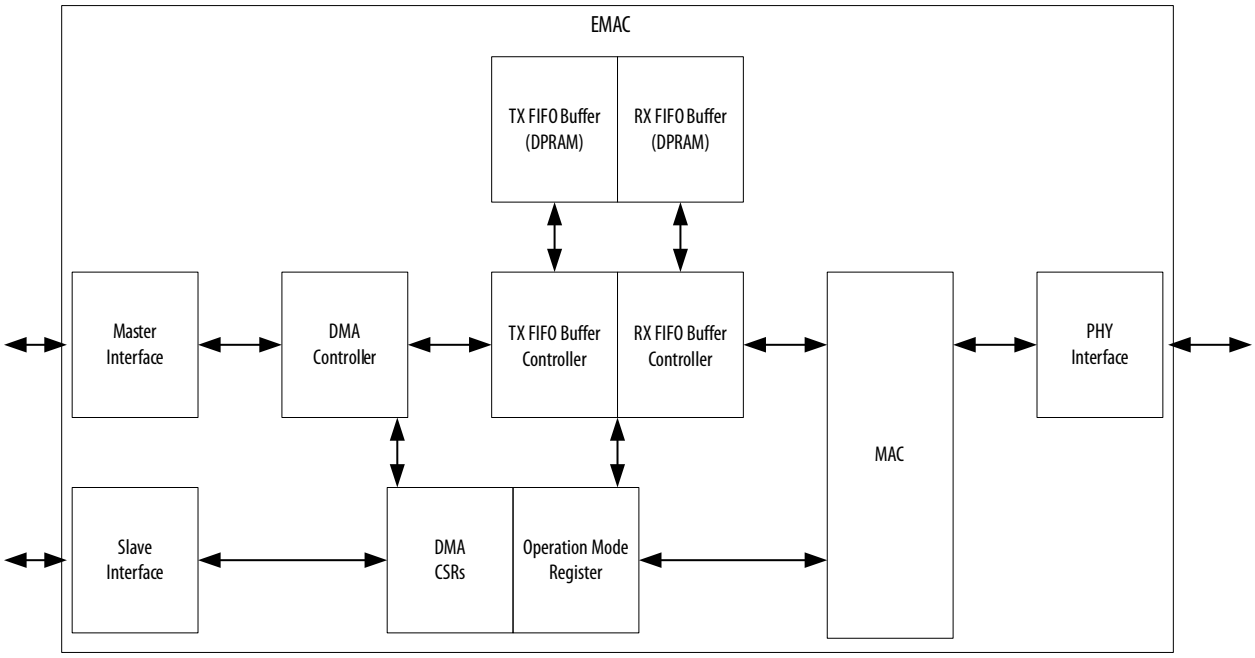
The following table lists the EMAC to FPGA IEEE1588 Timestamp Interface signals to and from each EMAC module.

Table 17-4: EMAC to FPGA IEEE 1588 Timestamp Interface Signals

Signal Name		In/Out	Width	Description
`f2h_emac_ptp_ref_clk`	Timestamp PTP Clock reference from the FPGA	In	1	Used as PTP Clock reference for each EMAC when the FPGA has implemented Timestamp capture interface. Common for all 3 EMACs.
`ptp_pps_o`	Pulse Per Second Output	Out	1	This signal is asserted based on the PPS mode selected in the Register 459 (PPS Control Register). Otherwise, this pulse signal is asserted every time the seconds counter is incremented. This signal is synchronous to `f2h_emac_ptp_ref_clk` and may only be sampled if the FPGA clock is used as timestamp reference.
`ptp_aux_ts_trig_i`	Auxiliary Timestamp Trigger	In	1	This signal is asserted to take an auxiliary snapshot of the time. The rising edge of this internal signal is used to trigger the auxiliary snapshot. The signal is synchronized internally with `clk_ptp_ref_i` which results in an additional delay of 3 cycles. This input is asynchronous input and its assertion period must be greater than 2 PTP active clocks to be sampled.

Functional Description of the EMAC

Figure 17-3: EMAC High-Level Block Diagram with Interfaces



There are two host interfaces to the Ethernet MAC. The management host interface, a 32-bit slave interface, provides access to the CSR set regardless of whether or not the EMACs are used directly through the FPGA fabric. The data interface is a 32-bit master interface, and it controls data transfer between the direct memory access (DMA) controller channels and the rest of the HPS system through the system interconnect.

The built-in DMA controller is optimized for data transfer between the MAC controller and system memory. The DMA controller has independent transmit and receive engines and a CSR set. The transmit engine transfers data from system memory to the device port, while the receive engine transfers data from the device port to the system memory. The controller uses descriptors to efficiently move data from source to destination with minimal host intervention.

The EMAC also contains FIFO buffer memory to buffer and regulate the Ethernet frames between the application system memory and the EMAC module. Each EMAC module has one 4 KB TX FIFO and one 4 KB RX FIFO. On transmit, the Ethernet frames write into the transmit FIFO buffer, and eventually trigger the EMAC to perform the transfer. Received Ethernet frames are stored in the receive FIFO buffer and the FIFO buffer fill level is communicated to the DMA controller. The DMA controller then initiates the configured burst transfers. Receive and transmit transfer statuses are read by the EMAC and transferred to the DMA.

Transmit and Receive Data FIFO Buffers

Each EMAC component has associated transmit and receive data FIFO buffers to regulate the frames between the application system memory and the EMAC. Both FIFO buffer instances are 1024 x 42 bits. The FIFO buffer word consists of:

- Data: 32 bits
- Sideband:
  - Byte enables (BE): 2 bits
  - End of frame (EOF): 1 bit
  - Error correction code (ECC): 7 bits

The data and sideband are protected by the 7-bit single error correct, double error detect (SECDED) code word.

The FIFO buffer RAMs have ECC enable, error injection and status pins. The enable and error injection pins are inputs driven by the system manager. The status pins are outputs driven to the MPU subsystem.

Note: The ECC block provides outputs to notify the system manager when single-bit correctable errors are detected (and corrected) and when double-bit uncorrectable errors are detected. The ECC logic also allows the injection of single-bit and double-bit errors for test purposes.

TX FIFO

The time at which data is sent from the TX FIFO to the EMAC is dependent on the transfer mode selected:

- Threshold mode: Data is popped from the TX FIFO when the number of bytes in the TX FIFO crosses the configured threshold level (or when the end of the frame is written before the threshold is crossed). The threshold level is configured using the TTC bit of Register 0 (Bus Mode Register).
- Store-and-Forward mode: Data is popped from the TX FIFO when one or more of the following conditions are true:
  - A complete frame is stored in the FIFO
  - The TX FIFO becomes almost full
  - The ATI watermark level becomes low. This case is only applicable when the Application Interface is used. The watermark becomes low when the requested FIFO does not have space to accommodate the requested burst length on the ATI.

The application can flush the TX FIFO of all contents by setting bit 20 (FTF) of Register 6 (Operation Mode Register). This bit is self-clearing and initializes the FIFO pointers to the default state. If the FTF bit is set during a frame transfer to the EMAC, further transfers are stopped because the FIFO is considered empty. This cessation causes an underflow event and a runt frame to be transmitted and the corresponding status word is forwarded to the DMA.

If a collision occurs in half-duplex mode operation before an end of the frame, the EMAC retries by popping the TX FIFO contents again.

Note: After more than 96 bytes (or 548 bytes in 1000 Mbps mode) are popped to the EMAC, the TX FIFO controller frees that space and makes it available to the DMA and a retry is not possible.

Note: When transmitting jumbo frames, the checksum offload feature must be disabled. Only packets of 4 KB or less can be supported when the checksum offload feature is enabled by software.

RX FIFO

Frames received by the EMAC are pushed into the RX FIFO. The fill level of the RX FIFO is indicated to the DMA when it crosses the configured receive threshold which is programmed by the RTC field of Register 6 (Operation Mode Register). The time at which data is sent from the RX FIFO to the DMA is dependent on the configuration of the RX FIFO:

- Cut-through (default) mode: When 64 bytes or a full packet of data is received into the FIFO, data is popped out of the FIFO and sent to the DMA until a complete packet has been transferred. Upon completion of the end-of-frame transfer, the status word is popped and sent to the DMA.
- Store and forward mode: A frame is read out only after being written completely in the RX FIFO. This mode is configured by setting the RSF bit of Register 6 (Operation Mode Register).

If the RX FIFO is full before it receives the EOF data from the EMAC, an overflow is declared and the whole frame (including the status word) is dropped and the overflow counter in the DMA, (Register 8) Missed Frame and Buffer Overflow Counter Register, is incremented. This outcome is true even if the Forward Error Frame (FEF) bit of Register 6 (Operation Mode Register) is set. If the start address of such a frame has already been transferred, the rest of the frame is dropped and a dummy EOF is written to the FIFO along with the status word. The status indicates a partial frame because of overflow. In such frames, the Frame Length field is invalid. If the RX FIFO is configured to operate in the store-and-forward mode and if the length of the received frame is more than the FIFO size, overflow occurs and all such frames are dropped.

Note: In store-and-forward mode, only received frames with length 4 KB or less prevent overflow errors and frames from being dropped.

DMA Controller

The DMA has independent transmit and receive engines, and a CSR space. The transmit engine transfers data from system memory to the device port or MAC transaction layer (MTL), while the receive engine transfers data from the device port to the system memory. Descriptors are used to efficiently move data from source to destination with minimal Host CPU intervention. The DMA is designed for packet-oriented data transfers such as frames in Ethernet. The controller can be programmed to interrupt the Host CPU for situations such as frame transmit and receive transfer completion as well as error conditions.

The DMA and the Host driver communicate through two data structures:†

- Control and Status registers (CSR)†
- Descriptor lists and data buffers †

Descriptor Lists and Data Buffers†

The DMA transfers data frames received by the MAC to the receive Buffer in the Host memory, and transmit data frames from the transmit Buffer in the Host memory. Descriptors that reside in the Host memory act as pointers to these buffers.†

There are two descriptor lists: one for reception and one for transmission. The base address of each list is written into Register 3 (Receive Descriptor List Address Register) and Register 4 (Transmit Descriptor List Address Register), respectively. A descriptor list is forward linked (either implicitly or explicitly). The last descriptor may point back to the first entry to create a ring structure. Explicit chaining of descriptors is accomplished by setting the second address chained in both receive and transmit descriptors (RDES1[24] and TDES1[24]). The descriptor lists resides in the Host physical memory address space. Each descriptor can point to a maximum of two buffers. This enables two buffers to be used, physically addressed, rather than contiguous buffers in memory.†

A data buffer resides in the Host physical memory space, and consists of an entire frame or part of a frame, but cannot exceed a single frame. Buffers contain only data, buffer status is maintained in the descriptor. Data chaining refers to frames that span multiple data buffers. However, a single descriptor cannot span multiple frames. The DMA skips to the next frame buffer when end-of-frame is detected. Data chaining can be enabled or disabled.†

Figure 17-4: Descriptor Ring Structure

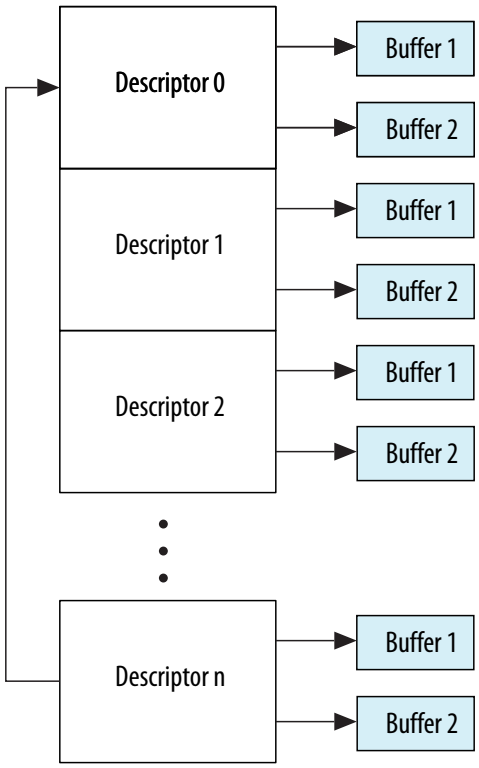


Figure 17-5: Descriptor Chain Structure

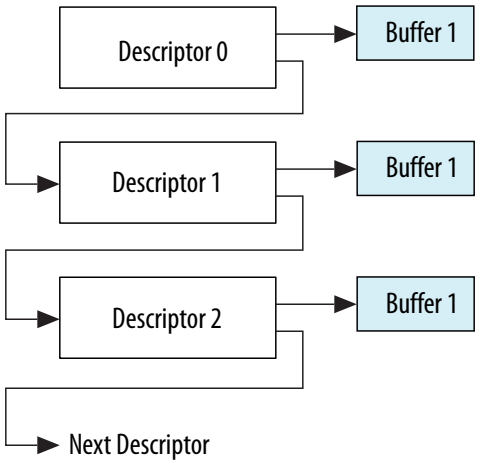

Note: You can select a descriptor structure during RTL configuration. The control bits in the descriptor structure are assigned so that the application can use an 8 KB buffer. All descriptions refer to the default descriptor structure.

Host Bus Burst Access

The DMA attempts to execute fixed-length burst transfers on the master interface if configured to do so through the FB bit of Register 0 (Bus Mode Register). The maximum burst length is indicated and limited by the PBL field (Bits [13:8]) Register 0 (Bus Mode Register). The receive and transmit descriptors are always accessed in the maximum possible (limited by packet burst length (PBL) or 16 * 8/bus width) burst size for the 16- bytes to be read.

The transmit DMA initiates a data transfer only when the MTL transmit FIFO has sufficient space to accommodate the configured burst or the number of bytes remaining in the frame (when it is less than the configured burst length). The DMA indicates the start address and the number of transfers required to the master interface. When the interface is configured for fixed-length burst, it transfers data using the best combination of INCR4, 8, or 16 and SINGLE transactions. When not configured for fixed-length burst, it transfers data using INCR (undefined length) and SINGLE transactions.

The receive DMA initiates a data transfer only when sufficient data to accommodate the configured burst is available in MTL receive FIFO buffer or when the end of frame (when it is less than the configured burst length) is detected in the receive FIFO buffer. The DMA indicates the start address and the number of transfers required to the master interface. When the interface is configured for fixed-length burst, it transfers data using the best combination of INCR4, 8, or 16 and SINGLE transactions. If the end-of-frame is reached before the fixed burst ends on the interface, then dummy transfers are performed in order to complete the fixed burst. If the FB bit of Register 0 (Bus Mode Register) is clear, it transfers data using INCR (undefined length) and SINGLE transactions.

When the interface is configured for address aligned words, both DMA engines ensure that the first burst transfer initiated is less than or equal to the size of the configured packet burst length. Thus, all subsequent beats start at an address that is aligned to the configured packet burst length. The DMA can only align the address for beats up to size 16 (for PBL > 16), because the interface does not support more than INCR16.

Host Data Buffer Alignment

The transmit and receive data buffers do not have any restrictions on start address alignment. For example, in systems with 32-bit memory, the start address for the buffers can be aligned to any of the four bytes. However, the DMA always initiates transfers with address aligned to the bus width with dummy data for the byte lanes not required. This typically happens during the transfer of the beginning or end of an Ethernet frame. The software driver should discard the dummy bytes based on the start address of the buffer and size of the frame.†

Example: Buffer Read

If the transmit buffer address is 0x00000FF2, and 15 bytes must be transferred, then the DMA reads five full words from address 0x00000FF0, but when transferring data to the MTL transmit FIFO buffer, the extra bytes (the first two bytes) are dropped or ignored. Similarly, the last 3 bytes of the last transfer are

also ignored. The DMA always ensures it transfers data in 32-bit increments to the MTL transmit FIFO buffer, unless it is the end-of-frame.

Example: Buffer Write

If the receive buffer address is 0x00000FF2 and 16 bytes of a received frame must be transferred, then the DMA writes 3 full words from address 0x00000FF0. But the first 2 bytes of first transfer and the last 2 bytes of the fourth transfer have dummy data.

Buffer Size Calculations

The DMA does not update the size fields in the transmit and receive descriptors. The DMA updates only the status fields (RDES and TDES) of the descriptors. The driver must perform the size calculations.

The transmit DMA transfers the exact number of bytes (indicated by the buffer size field of TDES1) to the MAC. If a descriptor is marked as th first (FS bit of TDES1 is set), then the DMA marks the first transfer from the buffer as the start of frame. If a descriptor is marked as the last (LS bit of TDES1), then the DMA marks the last transfer from that data buffer as the end-of-frame to the MTL.

The receive DMA transfers data to a buffer until the buffer is full or the end-of-frame is received from the MTL. If a descriptor is not marked as the last (LS bit of RDES0), then the descriptor's corresponding buffer(s) are full and the amount of valid data in a buffer is accurately indicated by its buffer size field minus the data buffer pointer offset when the FS bit of that descriptor is set. The offset is zero when the data buffer pointer is aligned to the data bus width. If a descriptor is marked as the last, then the buffer may not be full (as indicated by the buffer size in RDES1). To compute the amount of valid data in this final buffer, the driver must read the frame length (FL bits of RDES0[29:16]) and subtract the sum of the buffer sizes of the preceding buffers in this frame. The receive DMA always transfers the start of next frame with a new descriptor.

Note: Even when the start address of a receive buffer is not aligned to the data width of system bus, the system should allocate a receive buffer of a size aligned to the system bus width. For example, if the system allocates a 1,024-byte (1 KB) receive buffer starting from address 0x1000, the software can program the buffer start address in the receive descriptor to have a 0x1002 offset. The receive DMA writes the frame to this buffer with dummy data in the first two locations (0x1000 and 0x1001). The actual frame is written from location 0x1002. Thus, the actual useful space in this buffer is 1,022 bytes, even though the buffer size is programmed as 1,024 bytes, because of the start address offset.

Transmission

The DMA can transmit with or without an optional second frame (OSF).

Transmit Descriptor on page 17-27

TX DMA Operation: Default (Non-OSF) Mode

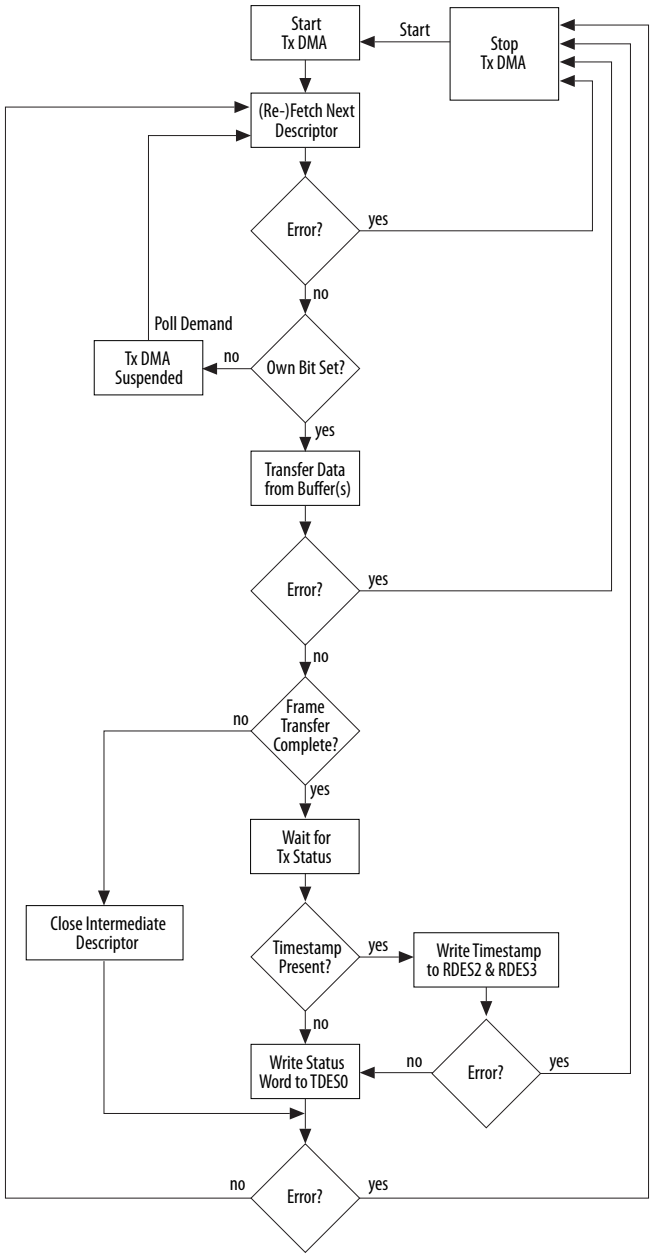
The transmit DMA engine in default mode proceeds as follows: †

1. The Host sets up the transmit descriptor (TDES0-TDES3) and sets the Own bit (TDES0[31]) after setting up the corresponding data buffer(s) with Ethernet frame data. †
2. When Bit 13 (ST) of Register 6 (Operation Mode Register) is set, the DMA enters the Run state. †
3. While in the Run state, the DMA polls the transmit descriptor list for frames requiring transmission. After polling starts, it continues in either sequential descriptor ring order or chained order. If the DMA detects a descriptor flagged as owned by the Host (TDES0[31] = 0), or if an error condition occurs, transmission is suspended and both the Bit 2 (Transmit Buffer Unavailable) and Bit 16

(Normal Interrupt Summary) of the Register 5 (Status Register) are set. The transmit Engine proceeds to **step 9**.

4. If the acquired descriptor is flagged as owned by DMA (TDES0[31] = 1), the DMA decodes the transmit Data Buffer address from the acquired descriptor.
5. The DMA fetches the transmit data from the Host memory and transfers the data to the MTL for transmission. †
6. If an Ethernet frame is stored over data buffers in multiple descriptors, the DMA closes the intermediate descriptor and fetches the next descriptor. Repeat **step 3**, **step 4**, and **step 5** until the end-of-Ethernet-frame data is transferred to the MTL. †
7. When frame transmission is complete, if IEEE 1588 timestamping was enabled for the frame (as indicated in the transmit status) the timestamp value obtained from MTL is written to the transmit descriptor (TDES2 and TDES3) that contains the end-of-frame buffer. The status information is then written to this transmit descriptor (TDES0). Because the Own bit is cleared during this step, the Host now owns this descriptor. If timestamping was not enabled for this frame, the DMA does not alter the contents of TDES2 and TDES3. †
8. Bit 0 (Transmit Interrupt) of Register 5 (Status Register) is set after completing transmission of a frame that has Interrupt on Completion (TDES1[31]) set in its Last descriptor. The DMA engine then returns to **step 3**. †
9. In the Suspend state, the DMA tries to re-acquire the descriptor (and thereby return to **step 3**) when it receives a Transmit Poll demand and the Underflow Interrupt Status bit is cleared. †

Figure 17-6: TX DMA Operation in Default Mode



Related Information

TX DMA Operation: Default (Non-OSF) Mode on page 17-17

TX DMA Operation: OSF Mode

While in the Run state, the transmit process can simultaneously acquire two frames without closing the Status descriptor of the first [if Bit 2 (OSF) in Register 6 (Operation Mode Register) is set]. As the transmit process finishes transferring the first frame, it immediately polls the transmit descriptor list for the second

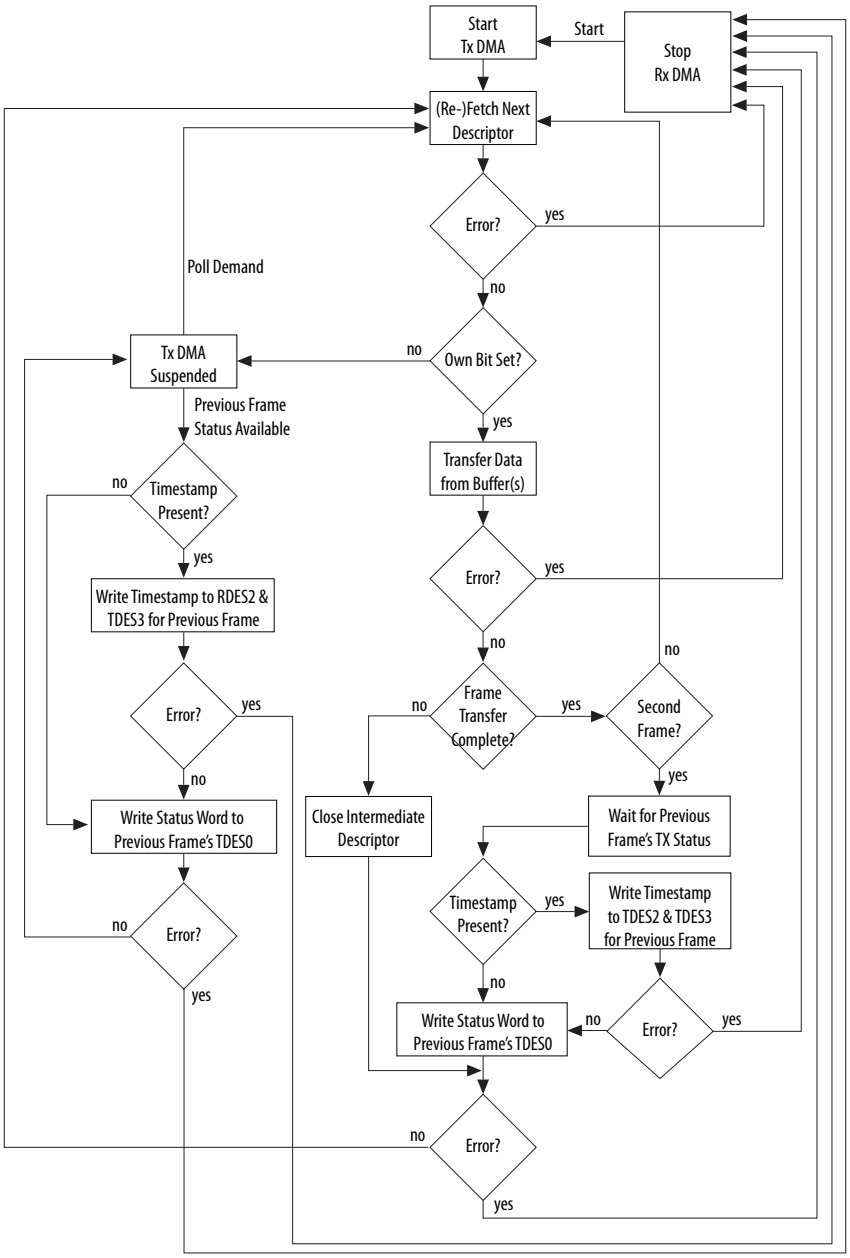
frame. If the second frame is valid, the transmit process transfers this frame before writing the first frame's status information. †

In OSF mode, the Run state transmit DMA operates in the following sequence: †

1. The DMA operates as described in steps 1 - 6 of the **TX DMA Operation: Default (Non-OSF) Mode** on page 17-17 section.
2. Without closing the previous frame's last descriptor, the DMA fetches the next descriptor. †
3. If the DMA owns the acquired descriptor, the DMA decodes the transmit buffer address in this descriptor. If the DMA does not own the descriptor, the DMA goes into Suspend mode and skips to **step 7**.†
4. The DMA fetches the transmit frame from the Host memory and transfers the frame to the MTL until the End-of-frame data is transferred, closing the intermediate descriptors if this frame is split across multiple descriptors. †
5. The DMA waits for the previous frame's frame transmission status and timestamp. Once the status is available, the DMA writes the timestamp to TDES2 and TDES3, if such timestamp was captured (as indicated by a status bit). The DMA then writes the status, with a cleared Own bit, to the corresponding TDES0, thus closing the descriptor. If timestamping was not enabled for the previous frame, the DMA does not alter the contents of TDES2 and TDES3. †
6. If enabled, the transmit interrupt is set, the DMA fetches the next descriptor, then proceeds to **step 3** (when Status is normal). If the previous transmission status shows an underflow error, the DMA goes into Suspend mode (**step 7**). †
7. In Suspend mode, if a pending status and timestamp are received from the MTL, the DMA writes the timestamp (if enabled for the current frame) to TDES2 and TDES3, then writes the status to the corresponding TDES0. It then sets relevant interrupts and returns to Suspend mode. †
8. The DMA can exit Suspend mode and enter the Run state (go to **step 1** or **step 2** depending on pending status) only after receiving a Transmit Poll demand (Register 1 (Transmit Poll Demand Register). †

Note: As the DMA fetches the next descriptor in advance before closing the current descriptor, the descriptor chain should have more than two different descriptors for correct and proper operation. †

Figure 17-7: TX DMA Operation in OSF Mode



Transmit Frame Processing

The transmit DMA expects that the data buffers contain complete Ethernet frames, excluding preamble, pad bytes, and FCS fields and that the DA, SA, and Type/Len fields contain valid data. If the transmit descriptor indicates that the MAC must disable CRC or PAD insertion, the buffer must have complete Ethernet frames (excluding preamble), including the CRC bytes. †

Frames can be datachained and can span several buffers. Frames must be delimited by the First Descriptor (TDES1[29]) and the Last Descriptor (TDES1[30]), respectively. †

As transmission starts, the First Descriptor must have (TDES1[29]) set. When this occurs, frame data transfers from the Host buffer to the MTL transmit FIFO buffer. Concurrently, if the current frame has the Last Descriptor (TDES1[30]) clear, the transmit Process attempts to acquire the Next descriptor. The transmit Process expects this descriptor to have TDES1[29] clear. If TDES1[30] is clear, it indicates an intermediary buffer. If TDES1[30] is set, it indicates the last buffer of the frame. †

After the last buffer of the frame has been transmitted, the DMA writes back the final status information to the Transmit Descriptor 0 (TDES0) word of the descriptor that has the last segment set in Transmit Descriptor 1 (TDES1[30]). At this time, if Interrupt on Completion (TDES1[31]) is set, the Bit 0 (Transmit Interrupt) of Register 5 (Status Register) is set, the Next descriptor is fetched, and the process repeats. †

The actual frame transmission begins after the MTL transmit FIFO buffer has reached either a programmable transmit threshold (Bits [16:14] of Register 6 (Operation Mode Register)), or a full frame is contained in the FIFO buffer. There is also an option for Store and Forward Mode (Bit 21 of Register 6 (Operation Mode Register)). Descriptors are released (Own bit TDES0[31] clears) when the DMA finishes transferring the frame. †

Note: To ensure proper transmission of a frame and the next frame, you must specify a non-zero buffer size for the transmit descriptor that has the Last Descriptor (TDES1[30]) set. †

Transmit Polling Suspended

Transmit polling can be suspended by either of the following conditions: †

- The DMA detects a descriptor owned by the Host (TDES0[31]=0). To resume, the driver must give descriptor ownership to the DMA and then issue a Poll Demand command. †
- A frame transmission is aborted when a transmit error because of underflow is detected. The appropriate Transmit Descriptor 0 (TDES0) bit is set. †

If the DMA goes into SUSPEND state because of the first condition, then both Bit 16 (Normal Interrupt Summary) and Bit 2 (Transmit Buffer Unavailable) of Register 5 (Status Register) are set. If the second condition occur, both Bit 15 (Abnormal Interrupt Summary) and Bit 5 (Transmit Underflow) of Register 5 (Status Register) are set, and the information is written to Transmit Descriptor 0, causing the suspension. †

In both cases, the position in the transmit List is retained. The retained position is that of the descriptor following the Last descriptor closed by the DMA. †

The driver must explicitly issue a Transmit Poll Demand command after rectifying the suspension cause. †

Reception

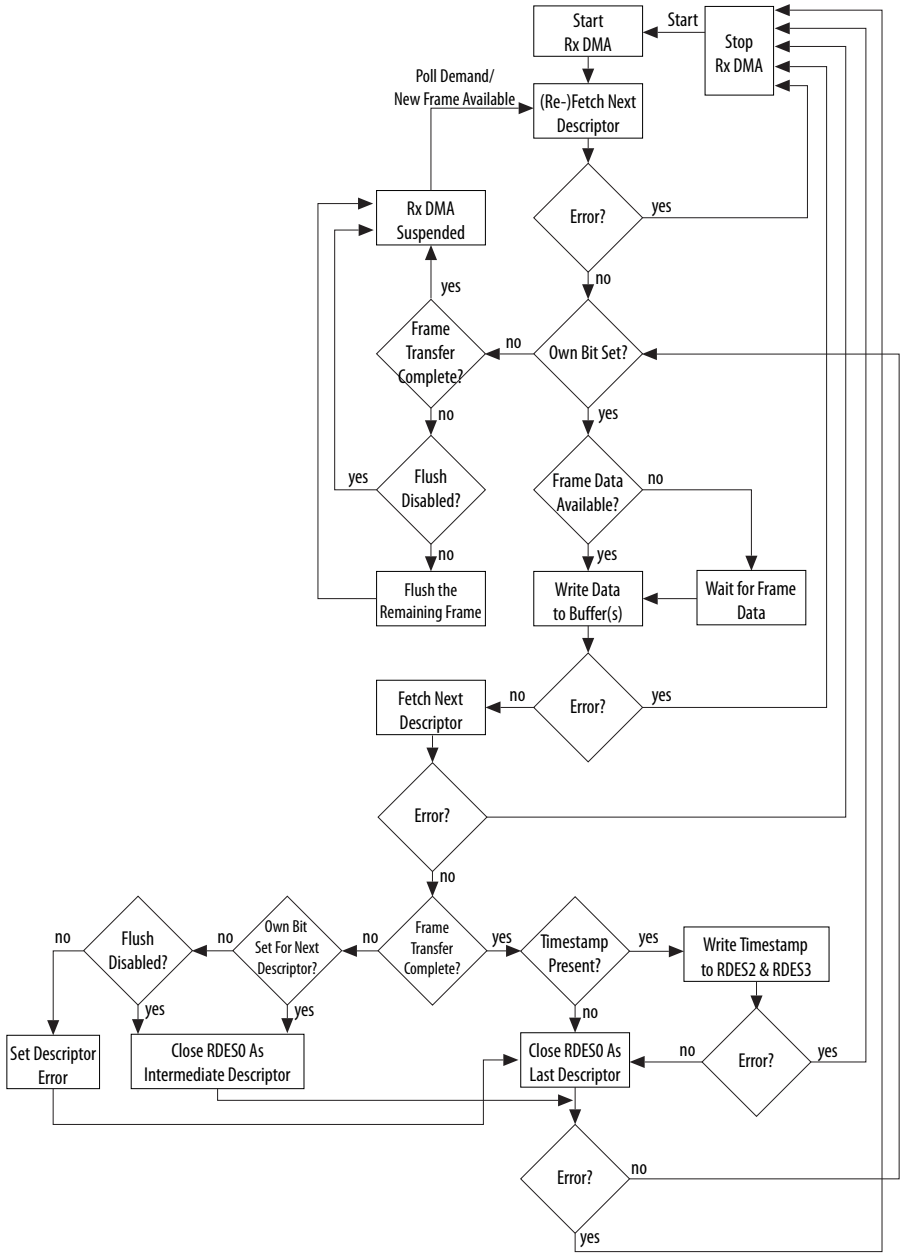
Receive functions use receive descriptors.

The receive DMA engine's reception sequence is proceeds as follows:

1. The host sets up receive descriptors (RDES0-RDES3) and sets the Own bit (RDES0[31]).†
2. When Bit 1 (SR) of Register 6 (Operation Mode Register) is set, the DMA enters the Run state. While in the Run state, the DMA polls the receive descriptor list, attempting to acquire free descriptors. If the fetched descriptor is not free (is owned by the host), the DMA enters the Suspend state and jumps to **step 9**.†
3. The DMA decodes the receive data buffer address from the acquired descriptors.†
4. Incoming frames are processed and placed in the acquired descriptor's data buffers.†
5. When the buffer is full or the frame transfer is complete, the receive engine fetches the next descriptor.†

6. If the current frame transfer is complete, the DMA proceeds to **step 7**. If the DMA does not own the next fetched descriptor and the frame transfer is not complete (EOF is not yet transferred), the DMA sets the Descriptor Error bit in the RDES0 (unless flushing is disabled in Bit 24 of Register 6 (Operation Mode Register)). The DMA closes the current descriptor (clears the Own bit) and marks it as intermediate by clearing the Last Segment (LS) bit in the RDES0 value (marks it as Last Descriptor if flushing is not disabled), then proceeds to **step 8**. If the DMA does own the next descriptor but the current frame transfer is not complete, the DMA closes the current descriptor as intermediate and reverts to **step 4**.†
7. If IEEE 1588 timestamping is enabled, the DMA writes the timestamp (if available) to the current descriptor's RDES2 and RDES3. It then takes the receive frame's status from the MTL and writes the status word to the current descriptor's RDES0, with the Own bit cleared and the Last Segment bit set.†
8. The receive engine checks the latest descriptor's Own bit. If the host owns the descriptor (Own bit is 0), the Bit 7 (Receive Buffer Unavailable) of Register 5 (Status Register) is set and the DMA receive engine enters the Suspended state (Step 9). If the DMA owns the descriptor, the engine returns to **step 4** and awaits the next frame.
9. Before the receive engine enters the Suspend state, partial frames are flushed from the receive FIFO buffer. You can control flushing using Bit 24 of Register 6 (Operation Mode Register). †
10. The receive DMA exits the Suspend state when a Receive Poll demand is given or the start of next frame is available from the MTL's receive FIFO buffer. The engine proceeds to **step 2** and refetches the next descriptor. †

Figure 17-8: Receive DMA Operation



When software has enabled timestamping through the `tsena` bit of register 448 (Timestamp Control Register) and a valid timestamp value is not available for the frame (for example, because the receive FIFO buffer was full before the timestamp could be written to it), the DMA writes all ones to RDES2 and RDES3 descriptors . Otherwise (that is, if timestamping is not enabled), the RDES2 and RDES3 descriptors remain unchanged.

Related Information

Receive Descriptor

Receive Descriptor Acquisition

The receive Engine always attempts to acquire an extra descriptor in anticipation of an incoming frame. Descriptor acquisition is attempted if any of the following conditions is satisfied: †

- Bit 1 (Start or Stop Receive) of Register 6 (Operation Mode Register) has been set immediately after being placed in the Run state. †
- The data buffer of the current descriptor is full before the frame ends for the current transfer. †
- The controller has completed frame reception, but the current receive descriptor is not yet closed. †
- The receive process has been suspended because of a host-owned buffer (RDES0[31] = 0) and a new frame is received. †
- A Receive poll demand has been issued. †

Receive Frame Processing

The MAC transfers the received frames to the Host memory only when the frame passes the address filter and frame size is greater than or equal to the configurable threshold bytes set for the receive FIFO buffer of MTL, or when the complete frame is written to the FIFO buffer in store-and-forward mode. †

If the frame fails the address filtering, it is dropped in the MAC block itself (unless Bit 31 (Receive All) of Register 1 (MAC Frame Filter) is set). Frames that are shorter than 64 bytes, because of collision or premature termination, can be removed from the MTL receive FIFO buffer. †

After 64 (configurable threshold) bytes have been received, the MTL block requests the DMA block to begin transferring the frame data to the receive buffer pointed by the current descriptor. The DMA sets the First Descriptor (RDES0[9]) after the DMA Host interface becomes ready to receive a data transfer (if the DMA is not fetching transmit data from the host), to delimit the frame. The descriptors are released when the Own (RDES[31]) bit is clear, either as the Data buffer fills up or as the last segment of the frame is transferred to the receive buffer. If the frame is contained in a single descriptor, both Last Descriptor (RDES[8]) and First Descriptor (RDES[9]) are set.

The DMA fetches the next descriptor, sets the Last Descriptor (RDES[8]) bit, and releases the RDES0 status bits in the previous frame descriptor. Then the DMA sets bit 6 (Receive Interrupt) of Register 5 (Status Register). The same process repeats unless the DMA encounters a descriptor flagged as being owned by the host. If this occurs,Bit 7 (Receive Buffer Unavailable) of Register 5 (Status Register) is set and the receive process enters the Suspend state. The position in the receive list is retained. †

Receive Process Suspended

If a new receive frame arrives while the receive process is in the suspend state, the DMA refetches the current descriptor in the Host memory. If the descriptor is now owned by the DMA, the receive process re-enters the run state and starts frame reception. If the descriptor is still owned by the host, by default, the DMA discards the current frame at the top of the MTL RX FIFO buffer and increments the missed frame counter. If more than one frame is stored in the MTL EX FIFO buffer, the process repeats. †

The discarding or flushing of the frame at the top of the MTL EX FIFO buffer can be avoided by disabling Flushing (Bit 24 of Register 6 (Operation Mode Register)). In such conditions, the receive process sets the Receive Buffer Unavailable status and returns to the Suspend state. †

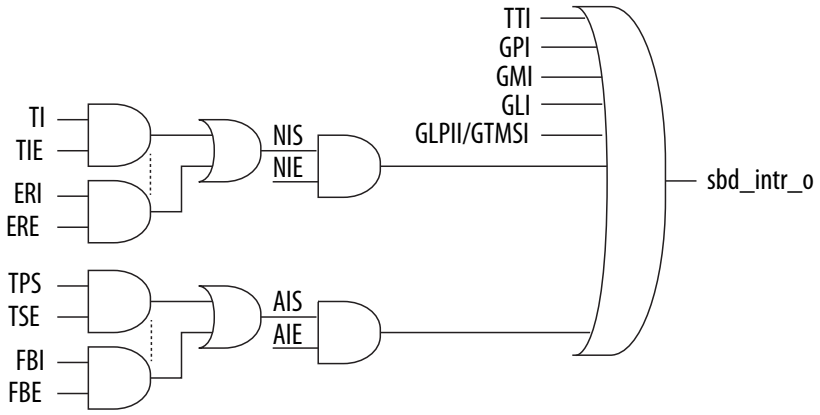
Interrupts

Interrupts can be generated as a result of various events. The DMA Register 5 (Status Register) contains a status bit for each of the events that can cause an interrupt. Register 7 (Interrupt Enable Register) contains an enable bit for each of the possible interrupt sources.

There are two groups of interrupts, Normal and Abnormal, as described in Register 5 (Status Register). Interrupts are cleared by writing a 1 to the corresponding bit position. When all the enabled interrupts

within a group are cleared, the corresponding summary bit is cleared. When both the summary bits are cleared, the sbd_intr_o interrupt signal is deasserted. If the MAC is the cause for assertion of the interrupt, then any of the GLI, GMI, GPI, TTI, or GLPII bits of Register 5 (Status Register) are set to 1.

Figure 17-9: Summary Interrupt (sbd_intr_o) Generation[49]



Note: Register 5 (Status Register) is the interrupt status register. The interrupt pin (sbd_intr_o) is asserted because of any event in this status register only if the corresponding interrupt enable bit is set in Register 7 (Interrupt Enable Register). †

Interrupts are not queued, and if the interrupt event occurs before the driver has responded to it, no additional interrupts are generated. For example, Bit 6 (Receive Interrupt) of Register 5 (Status Register) indicates that one or more frames were transferred to the Host buffer. The driver must scan all descriptors, from the last recorded position to the first one owned by the DMA.

An interrupt is generated only once for multiple, simultaneous events. The driver must scan Register 5 (Status Register) for the cause of the interrupt. After the driver has cleared the appropriate bit in Register 5 (Status Register), the interrupt is not generated again until a new interrupting event occurs. For example, the controller sets Bit 6 (Receive Interrupt) of Register 5 (Status Register) and the driver begins reading Register 5 (Status Register). Next, the interrupt indicated by Bit 7 (Receive Buffer Unavailable) of Register 5 (Status Register) occurs. The driver clears the receive interrupt (bit 6). However, the sbd_intr_o signal is not deasserted, because of the active or pending Receive Buffer Unavailable interrupt.

Bits 7:0 (riwt field) of Register 9 (Receive Interrupt Watchdog Timer Register) provide for flexible control of the receive interrupt. When this Interrupt timer is programmed with a non-zero value, it gets activated as soon as the RX DMA completes a transfer of a received frame to system memory without asserting the receive Interrupt because it is not enabled in the corresponding Receive Descriptor (RDES1[31]). When this timer runs out as per the programmed value, the AIS bit is set and the interrupt is asserted if the corresponding AIE is enabled in Register 7 (Interrupt Enable Register). This timer is disabled before it runs out, when a frame is transferred to memory, and the receive interrupt is triggered if it is enabled..

Error Response to DMA

If the slave replies with an error response to any data transfer initiated by a DMA channel, that DMA stops all operations and updates the error bits and the Fatal Bus Error bit in the Register 5 (Status Register). The DMA controller can resume operation only after soft resetting or hard resetting the EMAC and reinitializing the DMA.

Descriptor Overview

The DMA in the Ethernet subsystem transfers data based on a single enhanced descriptor, as explained in the DMA Controller section. The enhanced descriptor is created in the system memory. The descriptor addresses must be word-aligned.

The enhanced or alternate descriptor format can have 8 DWORDS (32 bytes) instead of 4 DWORDS as in the case of the normal descriptor format.

The features of the enhanced or alternate descriptor structure are:

- The alternative descriptor structure is implemented to support buffers of up to 8 KB (useful for Jumbo frames).†
- There is a re-assignment of control and status bits in TDES0, TDES1, RDES0 (advanced timestamp or IPC full offload configuration), and RDES1. †
- The transmit descriptor stores the timestamp in TDES6 and TDES7 when you select the advanced timestamp. †
- The receive descriptor structure is also used for storing the extended status (RDES4) and timestamp (RDES6 and RDES7) when advanced timestamp, IPC Full Checksum Offload Engine, or Layer 3 and Layer 4 filter feature is selected. †
- You can select one of the following options for descriptor structure:
  - If timestamping is enabled in Register 448 (Timestamp Control Register) or Checksum Offload is enabled in Register 0 (MAC Configuration Register), the software must to allocate 32 bytes (8 DWORDS) of memory for every descriptor by setting Bit 7 (Descriptor Size) of Register 0 (Bus Mode Register).
  - If timestamping or Checksum Offload is not enabled, the extended descriptors (DES4 to DES7) are not required. Therefore, software can use descriptors with the default size of 16 bytes (4 DWORDS) by clearing Bit 7 (Descriptor Size) of Register 0 (Bus Mode Register) to 0.

  Detailed bit map of the descriptor structure

Transmit Descriptor

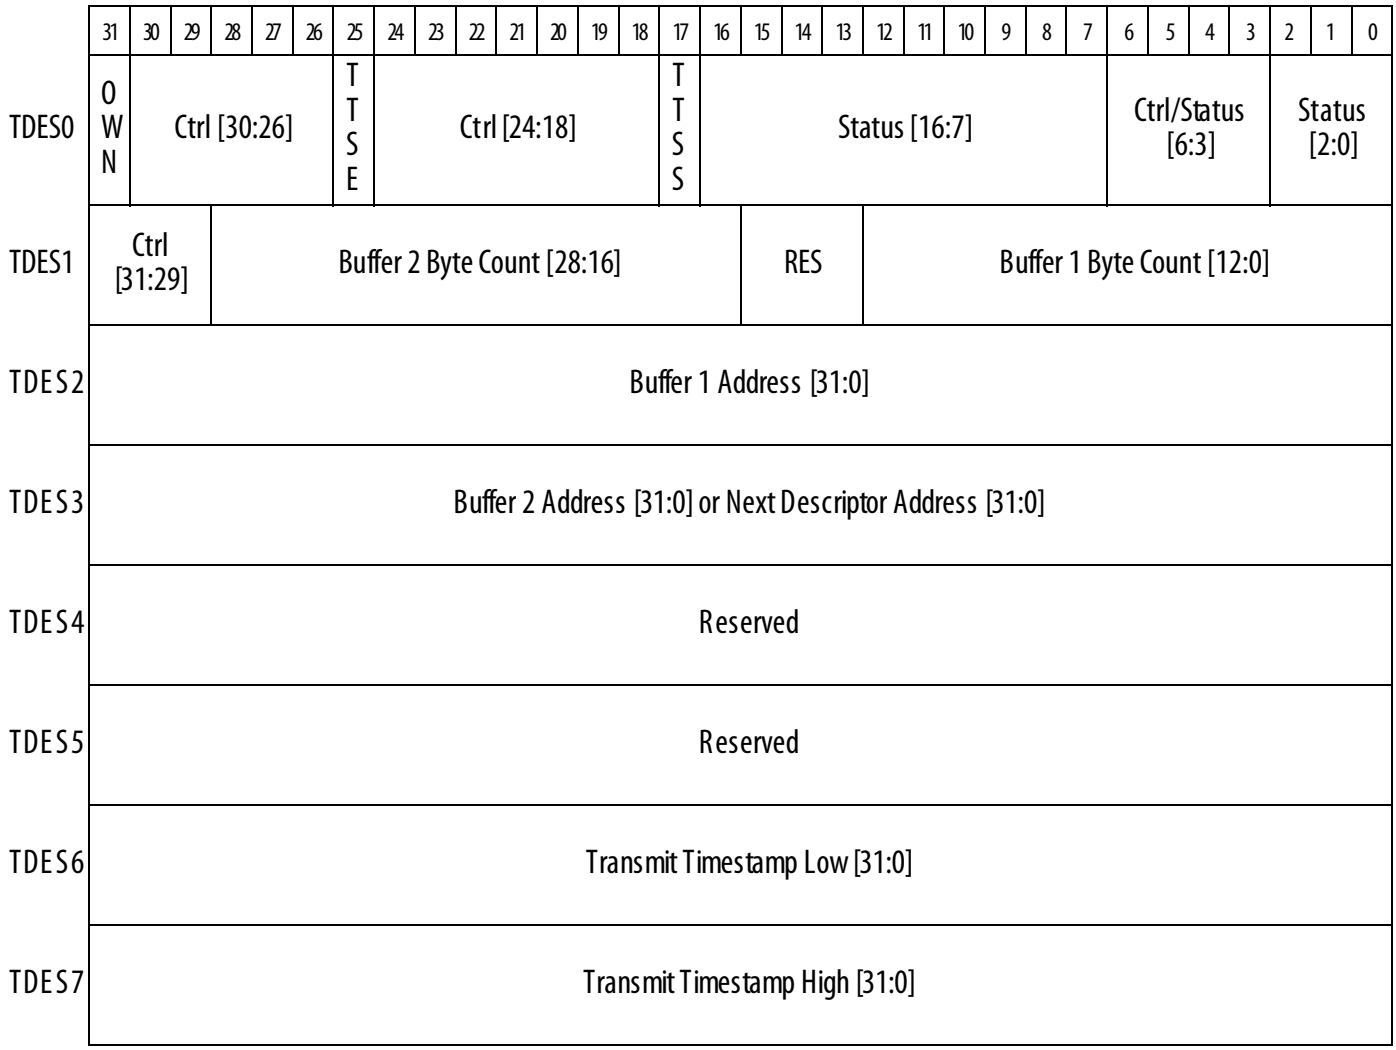
The application software must program the control bits TDES0[31:18] during the transmit descriptor initialization. When the DMA updates the descriptor, it writes back all the control bits except the OWN bit (which it clears) and updates the status bits[7:0].

With the advance timestamp support, the snapshot of the timestamp to be taken can be enabled for a given frame by setting Bit 25 (TTSE) of TDES0. When the descriptor is closed (that is, when the OWN bit is cleared), the timestamp is written into TDES6 and TDES7 as indicated by the status Bit 17 (TTSS) of TDES0.

Note: Only enhanced descriptor formats (4 or 8 DWORDS) are supported.

Note: When the advanced timestamp feature is enabled, software should set Bit 7 of Register 0 (Bus Mode Register), so that the DMA operates with extended descriptor size. When this control bit is clear, the TDES4-TDES7 descriptor space is not valid. †

Figure 17-10: Transmit Enhanced Descriptor Fields - Format



The DMA always reads or fetches four DWORDS of the descriptor from system memory to obtain the buffer and control information. †

Figure 17-11: Transmit Descriptor Fetch (Read) Format

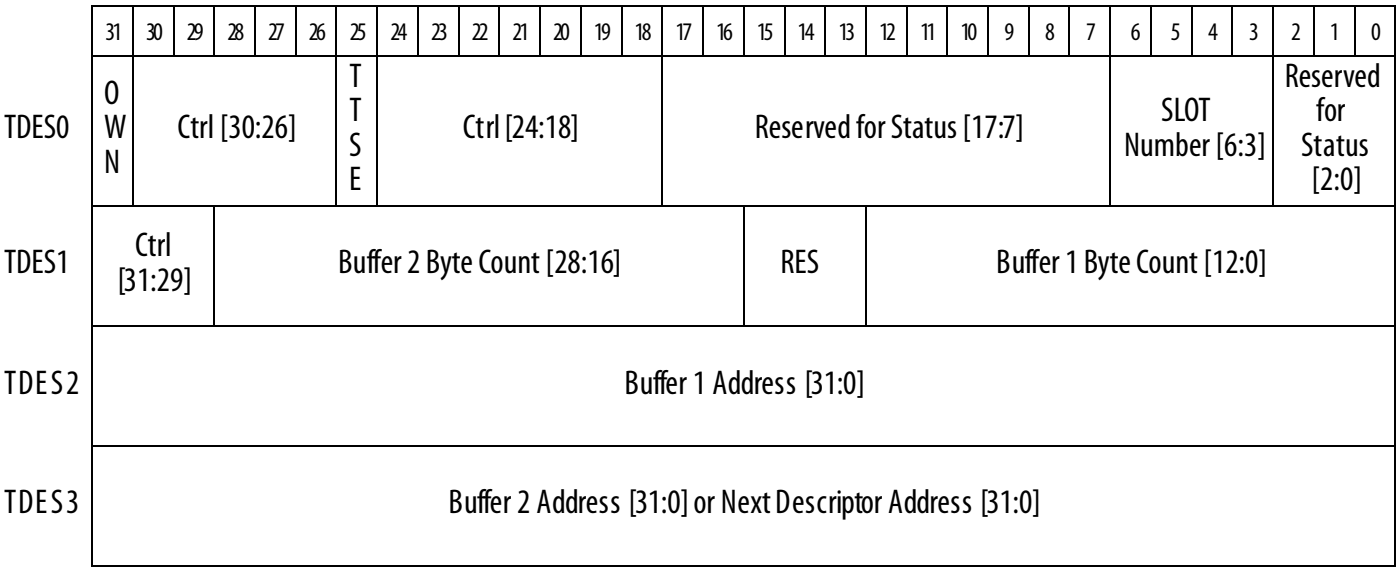


Table 17-5: Transmit Descriptor Word 0 (TDES0)

Bit	Description
31	OWN: Own Bit When set, this bit indicates that the descriptor is owned by the DMA. When this bit is cleared, it indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame transmission or when the buffers allocated in the descriptor are read completely. The ownership bit of the frame's first descriptor must be set after all subsequent descriptors belonging to the same frame have been set to avoid a possible race condition between fetching a descriptor and the driver setting an ownership bit. †
30	IC: Interrupt on Completion When set, this bitenables the Transmit Interrupt (Register 5[0]) to be set after the present frame has been transmitted. †
29	LS: Last Segment When set, this bit indicates that the buffer contains the last segment of the frame. When this bit is set, the TBS1 or TBS2 field in TDES1 should have a non-zero value. †
28	FS: First Segment When set, this bit indicates that the buffer contains the first segment of a frame. †
27	DC: Disable CRC When this bit is set, the MAC does not append a CRC to the end of the transmitted frame. This bit is valid only when the first segment (TDES0[28]) is set. †

Bit	Description
26	DP: Disable Pad When set, the MAC does not automatically add padding to a frame shorter than 64 bytes. When this bit is cleared, the DMA automatically adds padding and CRC to a frame shorter than 64 bytes, and the CRC field is added despite the state of the DC (TDES0[27]) bit. This bit is valid only when the first segment (TDES0[28]) is set. †
25	TTSE: Transmit Timestamp Enable When set, this bit enables IEEE1588 hardware timestamping for the transmit frame referenced by the descriptor. This field is valid only when the First Segment control bit (TDES0[28]) is set.
24	Reserved
23:22	CIC: Checksum Insertion Control. These bits control the checksum calculation and insertion. The following list describes the bit encoding: ▪ 0x0: Checksum insertion disabled. ▪ 0x1: Only IP header checksum calculation and insertion are enabled. ▪ 0x2: IP header checksum and payload checksum calculation and insertion are enabled, but pseudoheader checksum is not calculated in hardware. ▪ 0x3: IP Header checksum and payload checksum calculation and insertion are enabled, and pseudoheader checksum is calculated in hardware. This field is valid when the First Segment control bit (TDES0[28]) is set.
21	TER: Transmit End of Ring When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a descriptor ring. †
20	TCH: Second Address Chained When set, this bit indicates that the second address in the descriptor is the Next descriptor address rather than the second buffer address. When TDES0[20] is set, TBS2 (TDES1[28:16]) is a “don’t care” value. TDES0[21] takes precedence over TDES0[20]. †
19:18	LC: Late Collision When set, this bit indicates that frame transmission is aborted because of a collision occurring after the collision window (64-byte times, including preamble, in MII mode and 512-byte times, including preamble and carrier extension, in GMII mode). This bit is not valid if the underflow error bit is set.
17	TTSS: Transmit Timestamp Status This field is used as a status bit to indicate that a timestamp was captured for the described transmit frame. When this bit is set, TDES2 and TDES3 have a timestamp value captured for the transmit frame. This field is only valid when the descriptor’s Last Segment control bit (TDES0[29]) is set. †

Bit	Description
16	IHE: IP Header Error When set, this bit indicates that the MAC transmitter detected an error in the IP datagram header. The transmitter checks the header length in the IPv4 packet against the number of header bytes received from the application and indicates an error status if there is a mismatch. For IPv6 frames, a header error is reported if the main header length is not 40 bytes. Furthermore, the Ethernet Length/Type field value for an IPv4 or IPv6 frame must match the IPheader version received with the packet. For IPv4 frames, an error status is also indicated if the Header Length field has a value less than 0x5. †
15	ES: Error Summary Indicates the logical OR of the following bits: ▪ TDES0[14]: Jabber Timeout ▪ TDES0[13]: Frame Flush ▪ TDES0[11]: Loss of Carrier ▪ TDES0[10]: No Carrier ▪ TDES0[9]: Late Collision ▪ TDES0[8]: Excessive Collision ▪ TDES0[2]: Excessive Deferral ▪ TDES0[1]: Underflow Error ▪ TDES0[16]: IP Header Error ▪ TDES0[12]: IP Payload Error †
14	JT: Jabber Timeout When set, this bit indicates the MAC transmitter has experienced a jabber time-out. This bit is only set when Bit 22 (Jabber Disable) of Register 0 (MAC Configuration Register) is not set. †
13	FF: Frame Flushed When set, this bit indicates that the DMA or MTL flushed the frame because of a software Flush command given by the CPU. †
12	IPE: IP Payload Error When set, this bit indicates that MAC transmitter detected an error in the TCP, UDP, or ICMP IP datagram payload. The transmitter checks the payload length received in the IPv4 or IPv6 header against the actual number of TCP, UDP, or ICMP packet bytes received from the application and issues an error status in case of a mismatch. †

Bit	Description
11	LC: Loss of Carrier When set, this bit indicates that a loss of carrier occurred during frame transmission (that is, the gmii_crs_i signal was inactive for one or more transmit clock periods during frame transmission). This bit is valid only for the frames transmitted without collision when the MAC operates in the half-duplex mode. †
10	NC: No Carrier When set, this bit indicates that the Carrier Sense signal form the PHY was not asserted during transmission. †
9	Reserved
8	EC: Excessive Collision When set, this bit indicates that the transmission was aborted after 16 successive collisions while attempting to transmit the current frame. If Bit 9 (Disable Retry) in Register 0 (MAC Configuration Register) is set, this bit is set after the first collision, and the transmission of the frame is aborted. †
7	VF: VLAN Frame When set, this bit indicates that the transmitted frame is a VLAN-type frame. †
6:3	CC: Collision Count (Status field) These status bits indicate the number of collisions that occurred before the frame was transmitted. This count is not valid when the Excessive Collisions bit (TDES0[8]) is set. The EMAC updates this status field only in the half-duplex mode.
2	ED: Excessive Deferral When set, this bit indicates that the transmission has ended because of excessive deferral of over 24,288 bit times (155,680 bits times in 1,000-Mbps mode or if Jumbo frame is enabled) if Bit 4 (Deferral Check) bit in Register 0 (MAC Configuration Register) is set. †
1	UF: Underflow Error When set, this bit indicates that the MAC aborted the frame because the data arrived late from the Host memory. Underflow Error indicates that the DMA encountered an empty transmit buffer while transmitting the frame. The transmission process enters the Suspended state and sets both Transmit Underflow (Register 5[5]) and Transmit Interrupt (Register 5[0]). †
0	DB: Deferred Bit When set, this bit indicates that the MAC defers before transmission because of the presence of carrier. This bit is valid only in the half-duplex mode. †

Table 17-6: Transmit Descriptor Word 1 (TDES1)

Bit	Description
31:29	Reserved
28:16	TBS2: Transmit Buffer 2 Size This field indicates the second data buffer size in bytes. This field is not valid if TDES0[20] is set. †
15:13	Reserved †
12:0	TBS1: Transmit Buffer 1 Size This field indicates the first data buffer byte size, in bytes. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or the next descriptor, depending on the value of TCH (TDES0[20]). †

Table 17-7: Transmit Descriptor 2 (TDES2)

Bit	Description
31:09	Buffer 1 Address Pointer These bits indicate the physical address of Buffer 1. There is no limitation on the buffer address alignment. †

Table 17-8: Transmit Descriptor 3 (TDES3)

Bit	Description
31:09	Buffer 2 Address Pointer (Next Descriptor Address) Indicates the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (TDES1[24]) bit is set, this address contains the pointer to the physical memory where the Next descriptor is present. The buffer address pointer must be aligned to the bus width only when TDES1[24] is set. (LSBs are ignored internally.) †

Table 17-9: Transmit Descriptor 6 (TDES6)

Bit	Description
31:09	TTSL: Transmit Frame Timestamp Low This field is updated by DMA with the least significant 32 bits of the timestamp captured for the corresponding transmit frame. This field has the timestamp only if the Last Segment bit (LS) in the descriptor is set and Timestamp status (TTSS) bit is set. †

Table 17-10: Transmit Descriptor 7 (TDES7)

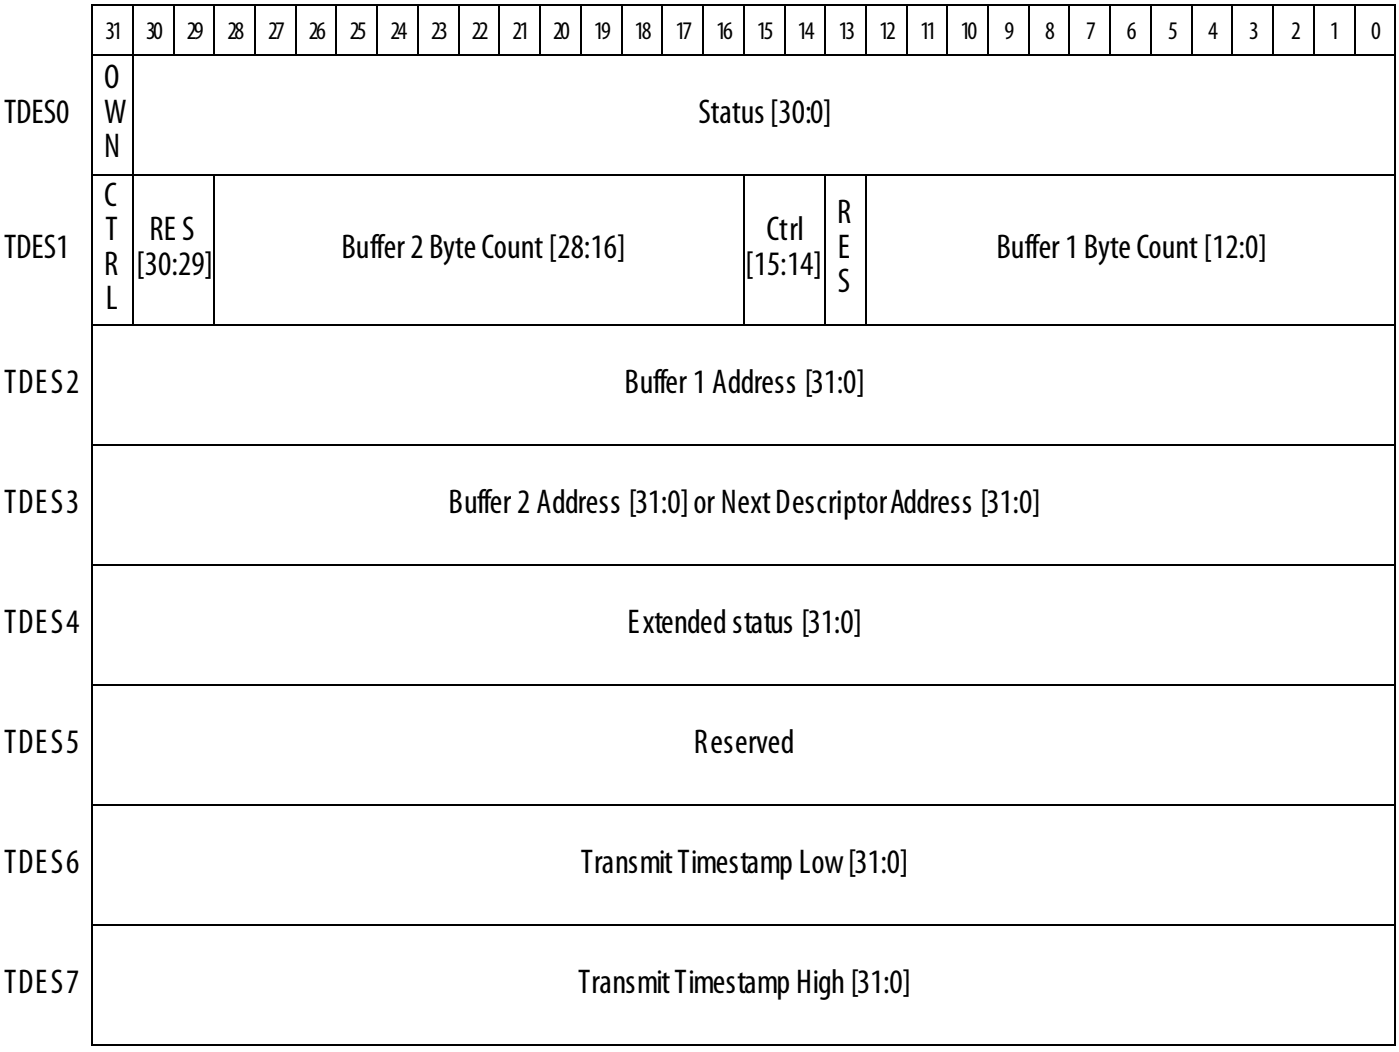
Bit	Description
31:09	TTSH: Transmit Frame Timestamp High This field is updated by DMA with the most significant 32 bits of the timestamp captured for the corresponding receive frame. This field has the timestamp only if the Last Segment bit (LS) in the descriptor is set and Timestamp status (TTSS) bit is set. †

Receive Descriptor

The receive descriptor can have 32 bytes of descriptor data (8 DWORDs) when advanced timestamp or IPC Full Offload feature is selected. When either of these features is enabled, software should set bit 7 of Register 0 (Bus Mode Register) so that the DMA operates with extended descriptor size. When this control bit is clear, the RDES0[0] is always cleared and the RDES4-RDES7 descriptor space is not valid. †

Note: Only enhanced descriptor formats (4 or 8 DWORDS) are supported.

Figure 17-12: Receive Enhanced Descriptor Fields Format



Receive Descriptor Field 0 (RDES0)

Table 17-11: Receive Descriptor Field 0 (RDES0)

Bit	Description
31	OWN: Own Bit When set, this bit indicates that the descriptor is owned by the DMA of the EMAC. When this bit is cleared, this bit indicates that the descriptor is owned by the Host. The DMA clears this bit either when it completes the frame reception or when the buffers that are associated with this descriptor are full.
30	AFM: Destination Address Filter Fail When set, this bit indicates a frame that failed in the DA Filter in the MAC. †
29:16	FL: Frame Length These bits indicate the byte length of the received frame that was transferred to host memory (including CRC). This field is valid when Last Descriptor (RDES0[8]) is set and either the Descriptor Error (RDES0[14]) or Overflow Error bits are cleared. The frame length also includes the two bytes appended to the Ethernet frame when IP checksum calculation (Type 1) is enabled and the received frame is not a MAC control frame. This field is valid when Last Descriptor (RDES0[8]) is set. When the Last Descriptor and Error Summary bits are not set, this field indicates the accumulated number of bytes that have been transferred for the current frame. †
15	ES: Error Summary Indicates the logical OR of the following bits: • RDES0[1]: CRC Error • RDES0[3]: Receive Error • RDES0[4]: Watchdog Timeout • RDES0[6]: Late Collision • RDES0[7]: Giant Frame • RDES4[4:3]: IP Header or Payload Error (Receive Descriptor Field 4 (RDES4)) • RDES0[11]: Overflow Error • RDES0[14]: Descriptor Error This field is valid only when the Last Descriptor (RDES0[8]) is set. †

Bit	Description
14	DE: Descriptor Error When set, this bit indicates a frame truncation caused by a frame that does not fit within the current descriptor buffers, and that the DMA does not own the Next descriptor. The frame is truncated. This bit is valid only when the Last Descriptor (RDES0[8]) bit is set. †
13	SAF: Source Address Filter Fail When set, this bit indicates that the SA field of frame failed the SA Filter in the MAC. †
12	LE: Length Error When set, this bit indicates that the actual length of the frame received and that the Length/ Type field does not match. This bit is valid only when the Frame Type (RDES0[5]) bit is clear. †
11	OE: Overflow Error When set, this bit indicates that the received frame was damaged because of buffer overflow in MTL. Note: This bit is set only when the DMA transfers a partial frame to the application, which happens only when the RX FIFO buffer is operating in the threshold mode. In the store-and-forward mode, all partial frames are dropped completely in the RX FIFO buffer. †
10	VLAN: VLAN Tag When set, this bit indicates that the frame to which this descriptor is pointing is a VLAN frame tagged by the MAC. The VLAN tagging depends on checking the VLAN fields of the received frame based on the Register 7 (VLAN Tag Register) setting. †
9	FS: First Descriptor When set, this bit indicates that this descriptor contains the first buffer of the frame. If the size of the first buffer is 0, the second buffer contains the beginning of the frame. If the size of the second buffer is also 0, the next descriptor contains the beginning of the frame. †
8	LS: Last Descriptor When set, this bit indicates that the buffers pointed to by this descriptor are the last buffers of the frame. †

Bit	Description
7	Timestamp Available, IP Checksum Error (Type1), or Giant Frame When the advanced timestamp feature is present, this bit is set to indicate that a snapshot of the Timestamp is written in descriptor words 6 (RDES6) and 7 (RDES7). This bit is valid only when the Last Descriptor bit (RDES0[8]) is set. When IP Checksum Engine (Type 1) is selected, this bit, is set to indicate that the 16-bit IPv4 Header checksum calculated by the EMAC did not match the received checksum bytes. Otherwise, this bit is set to indicate the Giant frame Status. Giant frames are larger than 1,518-byte (or 1,522-byte for VLAN or 2,000-byte when Bit 27 (2KPE) of MAC Configuration register is set) normal frames and larger than 9,018-byte (9,022-byte for VLAN) frame when Jumbo frame processing is enabled.
6	LC: Late Collision When set, this bit indicates that a late collision has occurred while receiving the frame in the half-duplex mode. †
5	FT: Frame Type When set, this bit indicates that the receive frame is an Ethernet-type frame (the LT field is greater than or equal to 0x0600) . When this bit is cleared, it indicates that the received frame is an IEEE802.3 frame. This bit is not valid for Runt frames less than 14 bytes.
4	RWT: Receive Watchdog Timeout When set, this bit indicates that the receive Watchdog Timer has expired while receiving the current frame and the current frame is truncated after the Watchdog Timeout. †
3	RE: Receive Error When set, this bit indicates that the `gmii_rxer_i` signal is asserted while `gmii_rxdv_i` is asserted during frame reception.
2	DE: Dribble Bit Error When set, this bit indicates that the received frame has a non-integer multiple of bytes (odd nibbles). This bit is valid only in the MII Mode. †

Bit	Description
1	CE: CRC Error When set, this bit indicates that a CRC error occurred on the received frame. This bit is valid only when the Last Descriptor (RDES0[8]) is set. †
0	Extended Status Available/RX MAC Address When either advanced timestamp or IP Checksum Offload (Type 2) is present, this bit, when set, indicates that the extended status is available in descriptor word 4 (RDES4). This bit is valid only when the Last Descriptor bit (RDES0[8]) is set. When the Advance Timestamp Feature or IPC Full Offload is not selected, this bit indicates RX MAC Address status. When set, this bit indicates that the RX MAC Address registers value (1 to 15) matched the frame's DA field. When clear, this bit indicates that the RX MAC Address Register 0 value matched the DA field. †

Receive Descriptor Field 1 (RDES1)

Table 17-12: Receive Descriptor Field 1 (RDES1)

Bit	Description
31	DIC: Disable Interrupt on Completion When set, this bit prevents setting the Status Register's RI bit (CSR5[6]) for the received frame ending in the buffer indicated by this descriptor. As a result, the RI interrupt for the frame is disabled and is not asserted to the Host.†
30:29	Reserved †
28:16	RBS2: Receive Buffer 2 Size These bits indicate the second data buffer size, in bytes. The buffer size must be a multiple of 4, even if the value of RDES3 (buffer2 address pointer) in the Receive Descriptor Field 3 (RDES3) is not aligned to the bus width. If the buffer size is not an appropriate multiple of 4, the resulting behavior is undefined. This field is not valid if RDES1[14] is set. For more information about calculating buffer sizes, refer to the Buffer Size Calculations section in this chapter.

Bit	Description
15	RER: Receive End of Ring When set, this bit indicates that the descriptor list reached its final descriptor. The DMA returns to the base address of the list, creating a descriptor ring. †
14	RCH: Second Address Chained When set, this bit indicates that the second address in the descriptor is the next descriptor address rather than the second buffer address. When this bit is set, RBS2 (RDES1[28:16]) is a "don't care" value. RDES1[15] takes precedence over RDES1[14]. †
13	Reserved †
12:0	RBS1: Receive Buffer 1 Size Indicates the first data buffer size in bytes. The buffer size must be a multiple of 4, even if the value of RDES2 (buffer1 address pointer), in the Receive Descriptor Field 2 (RDES2), is not aligned. When the buffer size is not a multiple of 4, the resulting behavior is undefined. If this field is 0, the DMA ignores this buffer and uses Buffer 2 or the next descriptor depending on the value of RCH (Bit 14). For more information about calculating buffer sizes, refer to the Buffer Size Calculations section in this chapter.

Receive Descriptor Fields (RDES2) and (RDES3)

Receive Descriptor Field 2 (RDES2)

Table 17-13: Receive Descriptor Field 2 (RDES2)

Bit	Description
31:0	Buffer 1 Address Pointer These bits indicate the physical address of Buffer 1. There are no limitations on the buffer address alignment except for the following condition: The DMA uses the value programmed in RDES2[1:0] for its address generation when the RDES2 value is used to store the start of the frame. The DMA performs a write operation with the RDES2[1:0] bits as 0 during the transfer of the start of the frame but the frame is shifted as per the actual buffer address pointer. The DMA ignores RDES2[1:0] if the address pointer is to a buffer where the middle or last part of the frame is stored. For more information about buffer address alignment, refer to the *Host Data Buffer Alignment* section.

Related Information

Host Data Buffer Alignment on page 17-16

Receive Descriptor Field 3 (RDES3)

Table 17-14: Receive Descriptor Field 3 (RDES3)

Bit	Description
31:0	Buffer 2 Address Pointer (Next Descriptor Address) These bits indicate the physical address of Buffer 2 when a descriptor ring structure is used. If the Second Address Chained (RDES1[24]) bit in Receive Descriptor Field 1 (RDES1) is set, this address contains the pointer to the physical memory where the Next descriptor is present. If RDES1[24], in the Receive Descriptor Field 1 (RDES1) is set, the buffer (Next descriptor) address pointer must be bus width-aligned (RDES3[1:0] = 0. LSBs are ignored internally.) However, when RDES1[24] in the Receive Descriptor Field 1 (RDES1) is cleared, there are no limitations on the RDES3 value, except for the following condition: the DMA uses the value programmed in RDES3 [1:0] for its buffer address generation when the RDES3 value is used to store the start of frame. The DMA ignores RDES3 [1:0] if the address pointer is to a buffer where the middle or last part of the frame is stored.

Receive Descriptor Field 4 (RDES4)

The extended status is written only when there is status related to IPC or timestamp available. The availability of extended status is indicated by Bit 0 in RDES0. This status is available only when the Advance Timestamp or IPC Full Offload feature is selected.

Table 17-15: Receive Descriptor Field 4 (RDES4)

Bit	Description
31:28	Reserved †
27:26	Layer 3 and Layer 4 Filter Number Matched These bits indicate the number of the Layer 3 and Layer 4 Filter that matched the received frame. • 00: Filter 0 • 01: Filter 1 • 10: Filter 2 • 11: Filter 3 This field is valid only when Bit 24 or Bit 25 is set. When more than one filter matches, these bits give only the lowest filter number. †

Bit	Description
25	Layer 4 Filter Match When set, this bit indicates that the received frame matches one of the enabled Layer 4 Port Number fields. This status is given only when one of the following conditions is true: • Layer 3 fields are not enabled and all enabled Layer 4 fields match. • All enabled Layer 3 and Layer 4 filter fields match. When more than one filter matches, this bit gives the layer 4 filter status of filter indicated by Bits [27:26]. †
24	Layer 3 Filter Match When set, this bit indicates that the received frame matches one of the enabled Layer 3 IP Address fields. This status is given only when one of the following conditions is true: • All enabled Layer 3 fields match and all enabled Layer 4 fields are bypassed. • All enabled filter fields match. When more than one filter matches, this bit gives the layer 3 filter status of the filter indicated by Bits [27:26]. †
23:15	Reserved
14	Timestamp Dropped When set, this bit indicates that the timestamp was captured for this frame but got dropped in the MTL RX FIFO buffer because of overflow.
13	PTP Version When set, this bit indicates that the received PTP message has the IEEE 1588 version 2 format. When clear, it has the version 1 format.
12	PTP Frame Type When set, this bit indicates that the PTP message is sent directly over Ethernet. When this bit is not set and the message type is non-zero, it indicates that the PTP message is sent over UDP-IPv4 or UDP-IPv6. The information about IPv4 or IPv6 can be obtained from Bits 6 and 7.

Bit	Description
11:8	Message Type These bits are encoded to give the type of the message received. • 0000: No PTP message received • 0001: SYNC (all clock types) • 0010: Follow_Up (all clock types) • 0011: Delay_Req (all clock types) • 0100: Delay_Resp (all clock types) • 0101: Pdelay_Req (in peer-to-peer transparent clock) • 0110: Pdelay_Resp (in peer-to-peer transparent clock) • 0111: Pdelay_Resp_Follow_Up (in peer-to-peer transparent clock) • 1000: Announce • 1001: Management • 1010: Signaling • 1011-1110: Reserved • 1111: PTP packet with Reserved message type
7	IPv6 Packet Received When set, this bit indicates that the received packet is an IPv6 packet. This bit is updated only when Bit 10 (IPC) of Register 0 (MAC Configuration Register) is set.
6	IPv4 Packet Received When set, this bit indicates that the received packet is an IPv4 packet. This bit is updated only when Bit 10 (IPC) of Register 0 (MAC Configuration Register) is set.
5	IP Checksum Bypassed When set, this bit indicates that the checksum offload engine is bypassed.
4	IP Payload Error When set, this bit indicates that the 16-bit IP payload checksum (that is, the TCP, UDP, or ICMP checksum) that the EMAC calculated does not match the corresponding checksum field in the received segment. It is also set when the TCP, UDP, or ICMP segment length does not match the payload length value in the IP Header field. This bit is valid when either Bit 7 or Bit 6 is set.
3	IP Header Error When set, this bit indicates that either the 16-bit IPv4 header checksum calculated by the EMAC does not match the received checksum bytes, or the IP datagram version is not consistent with the Ethernet Type value. This bit is valid when either Bit 7 or Bit 6 is set.

Bit	Description
2:0	IP Payload Type These bits indicate the type of payload encapsulated in the IP datagram processed by the receive Checksum Offload Engine (COE). The COE also sets these bits to 0 if it does not process the IP datagram's payload due to an IP header error or fragmented IP. • 0x0: Unknown or did not process IP payload • 0x1: UDP • 0x2: TCP • 0x3: ICMP • 0x4–0x7: Reserved This bit is valid when either Bit 7 or Bit 6 is set.

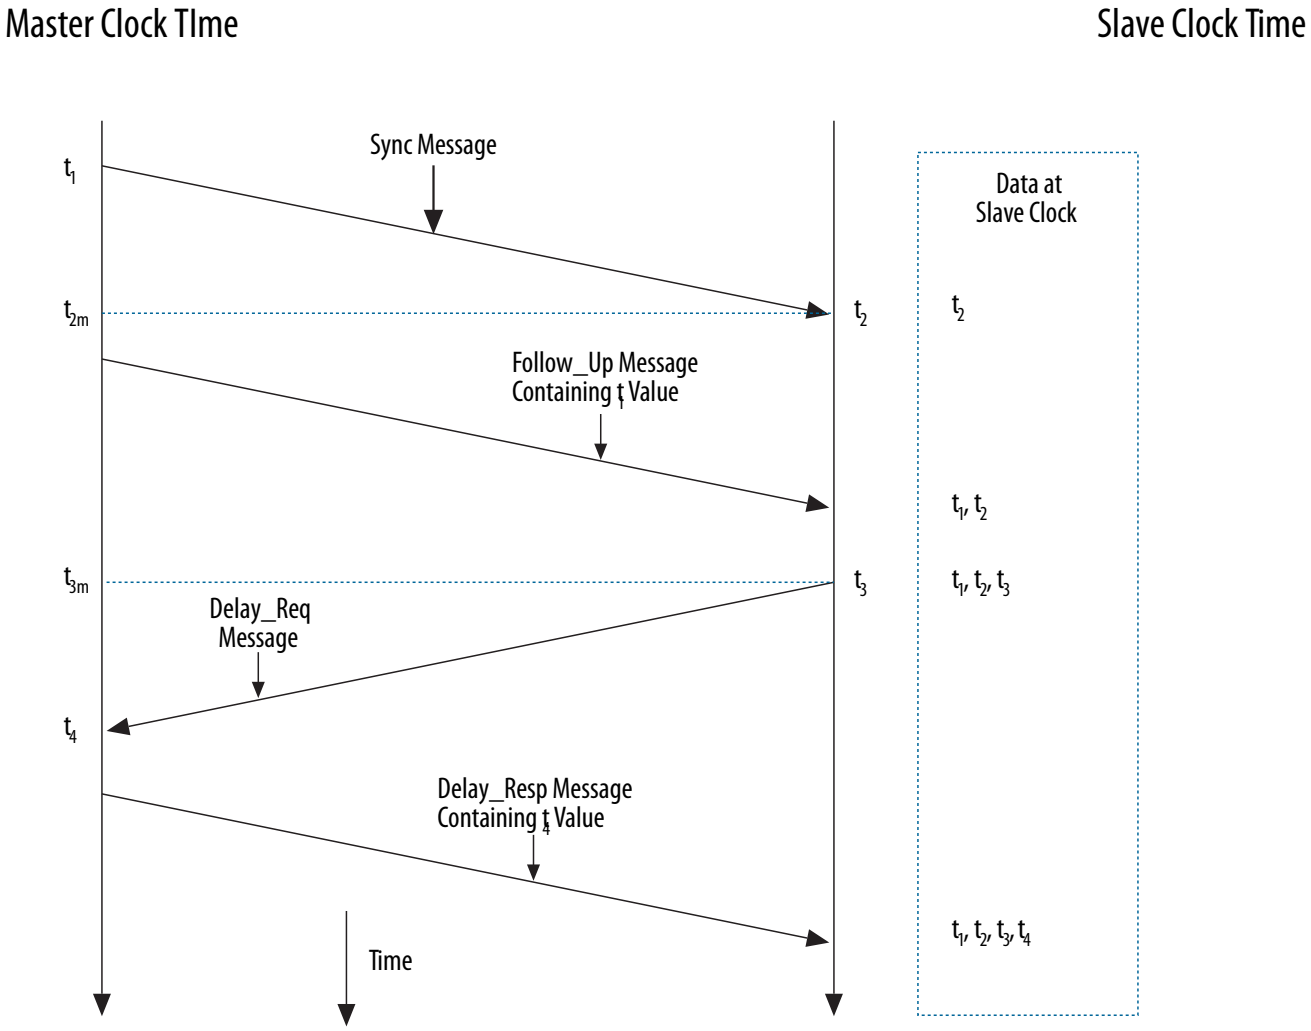
IEEE 1588-2002 Timestamps

The IEEE 1588-2002 standard defines the Precision Time Protocol (PTP) that enables precise synchronization of clocks in a distributed network of devices. The PTP applies to systems communicating by local area networks supporting multicast messaging. This protocol enables heterogeneous systems that include clocks of varying inherent precision, resolution, and stability to synchronize. It is frequently used in automation systems where a collection of communicating machines such as robots must be synchronized and hence operate over a common time base.(†)

The PTP is transported over UDP/IP. The system or network is classified into Master and Slave nodes for distributing the timing and clock information.†

The following figure shows the process that PTP uses for synchronizing a slave node to a master node by exchanging PTP messages.

Figure 17-13: Networked Time Synchronization



The PTP uses the following process for synchronizing a slave node to a master node by exchanging the PTP messages:

1. The master broadcasts the PTP Sync messages to all its nodes. The Sync message contains the master's reference time information. The time at which this message leaves the master's system is t1. This time must be captured, for Ethernet ports, at the PHY interface.†
2. The slave receives the sync message and also captures the exact time, t2, using its timing reference.†
3. The master sends a follow_up message to the slave, which contains t1 information for later use.†
4. The slave sends a delay_req message to the master, noting the exact time, t3, at which this frame leaves the PHY interface.†
5. The master receives the message, capturing the exact time, t4, at which it enters its system.†
6. The master sends the t4 information to the slave in the delay_resp message.†
7. The slave uses the four values of t1, t2, t3, and t4 to synchronize its local timing reference to the master's timing reference.†

Most of the PTP implementation is done in the software above the UDP layer. However, the hardware support is required to capture the exact time when specific PTP packets enter or leave the Ethernet port at

the PHY interface. This timing information must be captured and returned to the software for the proper implementation of PTP with high accuracy.†

The EMAC is intended to support IEEE 1588 operation in all modes with a resolution of 1 microsecond. When the two EMACs are operating in an IEEE 1588 environment, the MPU subsystem is responsible for maintaining synchronization between the time counters internal to the two MACs.

The IEEE 1588 interface to the FPGA allows the FPGA to provide a source for the `emac_ptp_ref_clk` input as well to allow it to monitor the pulse per second output from each EMAC controller.

The EMAC component provides a hardware assisted implementation of the IEEE 1588 protocol. Hardware support is for timestamp maintenance. Timestamps are updated when receiving any frame on the PHY interface, and the receive descriptor is updated with this value. Timestamps are also updated when the SFD of a frame is transmitted and the transmit descriptor is updated accordingly.†

For details about the IEEE 1588-2002 standard, refer to IEEE Standard 1588-2002 - IEEE Standard for a Precision Clock Synchronization Protocol for Networked Measurement and Control Systems, available on the IEEE Standards Association website.†

Reference Timing Source

To get a snapshot of the time, the EMAC takes the reference clock input and uses it to generate the reference time (64-bit) internally and capture timestamps.†

System Time Register Module

The 64-bit time is maintained in this module and updated using the input reference clock, `clk_ptp_ref`, which can be the `emac_ptp_clk` from the HPS or the `f2s_ptp_ref_clk` from the FPGA. The `emac_ptp_clk` in the HPS is a derivative of the `osc1_clk` and is configured in the clock manager. This input reference clock is the source for taking snapshots (timestamps) of Ethernet frames being transmitted or received at the PHY interface.

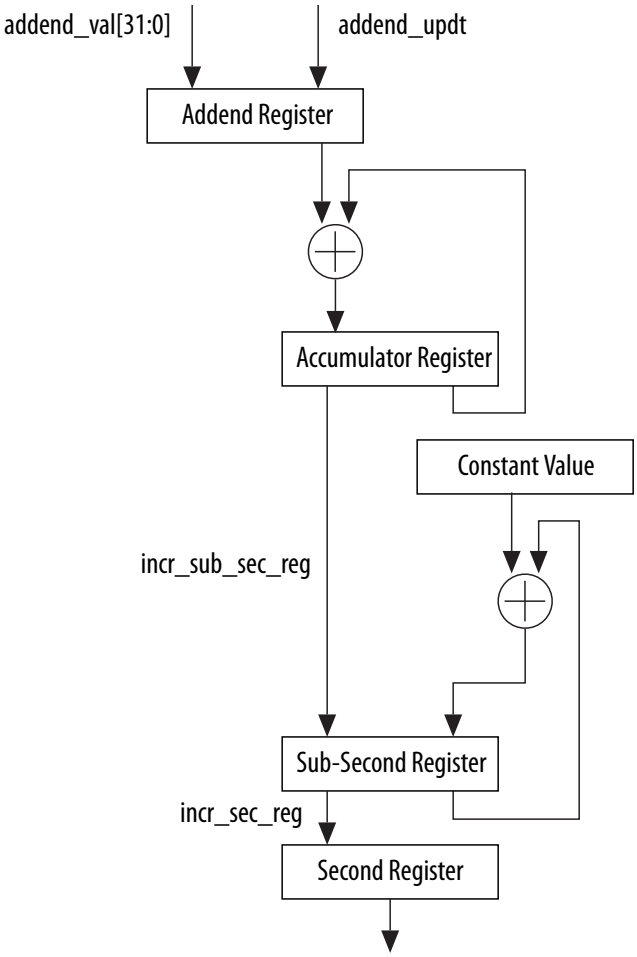
The system time counter can be initialized or corrected using the coarse correction method. In this method, the initial value or the offset value is written to the Timestamp Update register. For initialization, each EMAC's system time counter is written with the value in the Timestamp Update registers, while for system time correction, the offset value is added to or subtracted from the system time.

With the fine correction method, a slave clock's frequency drift with respect to the master clock is corrected over a period of time instead of in one clock, as in coarse correction. This protocol helps maintain linear time and does not introduce drastic changes (or a large jitter) in the reference time between PTP sync message intervals.†

With this method, an accumulator sums up the contents of the Timestamp_Addend register, as shown in the figure below. The arithmetic carry that the accumulator generates is used as a pulse to increment the system time counter. The accumulator and the addend are 32-bit registers. Here, the accumulator acts as a high-precision frequency multiplier or divider.

Note: You must connect a PTP clock with a frequency higher than the frequency required for the specified accuracy.†

Figure 17-14: Algorithm for System Time Update Using Fine Method



The System Time Update logic requires a 50-MHz clock frequency to achieve 20-ns accuracy. The frequency division ratio (FreqDivisionRatio) is the ratio of the reference clock frequency to the required clock frequency. Hence, if the reference clock (`clk_ptp_ref_i`) is for example, 66 MHz, this ratio is calculated as 66 MHz / 50 MHz = 1.32. Hence, the default addend value to program in the register is 232 / 1.32, 0xC1F07C1F.

If the reference clock drifts lower, to 65 MHz for example, the ratio is 65 / 50, or 1.3 and the value to set in the addend register is 232 / 1.30, or 0xC4EC4EC4. If the clock drifts higher, to 67 MHz for example, the addend register must be set to 0xBF0B7672. When the clock drift is nil, the default addend value of 0xC1F07C1F (232 / 1.32) must be programmed.[†]

In the above figure, the constant value used to accumulate the sub-second register is decimal 43, which achieves an accuracy of 20 ns in the system time (in other words, it is incremented in 20-ns steps).

The software must calculate the drift in frequency based on the Sync messages and update the Addend register accordingly.†

Initially, the slave clock is set with FreqCompensationValue0 in the Addend register. This value is as follows:†

$$FreqCompensationValue_0 = 232 / FreqDivisionRatio^{\dagger}$$

If MasterToSlaveDelay is initially assumed to be the same for consecutive sync messages, the algorithm described below must be applied. After a few sync cycles, frequency lock occurs. The slave clock can then determine a precise MasterToSlaveDelay value and re-synchronize with the master using the new value.†

The algorithm is as follows:†

- At time $MasterSyncTime_n$ the master sends the slave clock a sync message. The slave receives this message when its local clock is $SlaveClockTime_n$ and computes $MasterClockTime_n$ as:†

  $$MasterClockTime_n = MasterSyncTime_n + MasterToSlaveDelay_n^{\dagger}$$

- The master clock count for current sync cycle, $MasterClockCount_n$ is given by:†

  $$MasterClockCount_n = MasterClockTime_n - MasterClockTime_{n-1}$$

  (assuming that MasterToSlaveDelay is the same for sync cycles n and n – 1)†

- The slave clock count for current sync cycle, $SlaveClockCount_n$ is given by:†

  $$SlaveClockCount_n = SlaveClockTime_n - SlaveClockTime_{n-1}^{\dagger}$$

- The difference between master and slave clock counts for current sync cycle, $ClockDiffCount_n$ is given by:†

  $$ClockDiffCount_n = MasterClockCount_n - SlaveClockCount_n^{\dagger}$$

- The frequency-scaling factor for the slave clock, $FreqScaleFactor_n$ is given by:†

  $$FreqScaleFactor_n = (MasterClockCount_n + ClockDiffCount_n) / SlaveClockCount_n^{\dagger}$$

- The frequency compensation value for Addend register, $FreqCompensationValue_n$ is given by: †

  $$FreqCompensationValue_n = FreqScaleFactor_n \times FreqCompensationValue_{n-1} - 1^{\dagger}$$

In theory, this algorithm achieves lock in one Sync cycle; however, it may take several cycles, because of changing network propagation delays and operating conditions.†

This algorithm is self-correcting: if for any reason the slave clock is initially set to a value from the master that is incorrect, the algorithm corrects it at the cost of more Sync cycles.†

Transmit Path Functions

The MAC captures a timestamp when the start-of-frame data (SFD) is sent on the PHY interface. You can control the frames for which timestamps are captured on a per frame basis. In other words, each transmit frame can be marked to indicate whether a timestamp should be captured for that frame. †

You can use the conrol bits in the transmit descriptor to indicate whether a timestamp should be capture for a frame. The MAC returns the timestamp to the software inside the corrsponding transmit descriptor, thus connecting the timestamp automatically to the specific PTP frame. The 64-bit timestamp information is written to the TDES2 and TDES3 fields. T†

Receive Path Functions

The MAC captures the timestamp of all frames received on the PHY interface. The DMA returns the timestamp to the software in the corresponding receive descriptor. The timestamp is written only to the last receive descriptor.†

Timestamp Error Margin

According to the IEEE1588 specifications, a timestamp must be captured at the SFD of the transmitted and received frames at the PHY interface. Because the PHY interface receive and transmit clocks are not synchronous to the reference timestamp clock (`clk_ptp_ref`) a small amount of drift is introduced when a timestamp is moved between asynchronous clock domains. In the transmit path, the captured and reported timestamp has a maximum error margin of two PTP clocks, meaning that the captured timestamp has a reference timing source value that is occurred within two clocks after the SFD is transmitted on the PHY interface.

Similarly, in the receive path, the error margin is three PHY interface clocks, plus up to two PTP clocks. You can ignore the error margin due to the PHY interface clock by assuming that this constant delay is present in the system (or link) before the SFD data reaches the PHY interface of the MAC.†

Frequency Range of Reference Timing Clock

The timestamp information is transferred across asynchronous clock domains, from the EMAC clock domain to the FPGA clock domain. Therefore, a minimum delay is required between two consecutive timestamp captures. This delay is four PHY interface clock cycles and three PTP clock cycles. If the delay between two timestamp captures is less than this amount, the MAC does not take a timestamp snapshot for the second frame.

The maximum PTP clock frequency is limited by the maximum resolution of the reference time (20 ns resulting in 50 MHz) and the timing constraints achievable for logic operating on the PTP clock. In addition, the resolution, or granularity, of the reference time source determines the accuracy of the synchronization. Therefore, a higher PTP clock frequency gives better system performance.†

The minimum PTP clock frequency depends on the time required between two consecutive SFD bytes. Because the PHY interface clock frequency is fixed by the IEEE 1588 specification, the minimum PTP clock frequency required for proper operation depends on the operating mode and operating speed of the MAC.†

Table 17-18: Minimum PTP Clock Frequency Example

Mode	Minimum Gap Between Two SFDs	Minimum PTP Frequency
100-Mbps full-duplex operation	168 MII clocks (128 clocks for a 64-byte frame + 24 clocks of min IFG + 16 clocks of preamble)	(3 * PTP) + (4 * MII) <= 168 * MII, that is, ~0.5 MHz (168 – 4) * 40 ns ÷ 3 = 2180 ns period)
1000-Mbps half duplex operation	24 GMII clocks (4 for a jam pattern sent just after SFD because of collision + 12 IFG + 8 preamble)	(3 * PTP) + 4 * GMII <= 24 * GMII, that is, 18.75 MHz

Related Information

http://standards.ieee.ort/findstds/index.html

IEEE 1588-2008 Advanced Timestamps

In addition to the basic timestamp features mentioned in IEEE 1588-2002 Timestamps, the EMAC supports the following advanced timestamp features defined in the IEEE 1588-2008 standard.†

- Supports the IEEE 1588-2008 (version 2) timestamp format. †
- Provides an option to take a timestamp of all frames or only PTP-type frames. †
- Provides an option to take a timestamp of event messages only. †
- Provides an option to take the timestamp based on the clock type: ordinary, boundary, end-to-end, or peer-to-peer. †
- Provides an option to configure the EMAC to be a master or slave for ordinary and boundary clock. †
- Identifies the PTP message type, version, and PTP payload in frames sent directly over Ethernet and sends the status. †
- Provides an option to measure sub-second time in digital or binary format. †

Related Information

For more information about advanced timestamp features, refer to the *IEEE Standard 1588 - 2008 IEEE Standard for a Precision Clock Synchronization Protocol for Networked Measurement and Control System, available on the IEEE Standards Association website.*

Peer-to-Peer PTP Transparent Clock (P2P TC) Message Support

The IEEE 1588-2008 version supports Peer-to-Peer PTP (Pdelay) messages in addition to SYNC, Delay Request, Follow-up, and Delay Response messages.†

Clock Types

The EMAC supports the following clock types defined in the IEEE 1588-2008 standard:

- Ordinary clock†
- Boundary clock†
- End-to-End transparent clock†
- Peer-to-Peer transparent clock†

Reference Timing Source

The EMAC supports the following reference timing source features defined in the IEEE 1588-2008 standard:

- 48-bit seconds field†
- Fixed pulse-per-second output†
- Flexible pulse-per-second output†
- Auxiliary snapshots (timestamps) with external events

Transmit Path Functions

The advanced timestamp feature is supported through the descriptors format.

Receive Path Functions

The MAC processes the received frames to identify valid PTP frames. You can control the snapshot of the time to be sent to the application, by using the following options:†

- Enable timestamp for all frames.†
- Enable timestamp for IEEE 1588 version 2 or version 1 timestamp.†
- Enable timestamp for PTP frames transmitted directly over Ethernet or UDP/IP Ethernet.†
- Enable timestamp snapshot for the received frame for IPv4 or IPv6.†
- Enable timestamp snapshot for EVENT messages (SYNC, DELAY_REQ, PDELAY_REQ, or PDELAY_RESP) only.†
- Enable the node to be a master or slave and select the timestamp type to control the type of messages for which timestamps are taken.†

The DMA returns the timestamp to the software inside the corresponding transmit or receive descriptor.

Auxiliary Snapshot

The auxiliary snapshot feature allows you to store a snapshot (timestamp) of the system time based on an external event. The event is considered to be the rising edge of the sideband signal `ptp_aux_ts_trig_i` from the FPGA. One auxiliary snapshot input is available. The depth of the auxiliary snapshot FIFO buffer is 16.

The timestamps taken for any input are stored in a common FIFO buffer. The host can read Register 458 (Timestamp Status Register) to know which input's timestamp is available for reading at the top of this FIFO buffer.

Only 64-bits of the timestamp are stored in the FIFO. You can read the upper 16-bits of seconds from Register 457 (System Time - Higher Word Seconds Register) when it is present. When a snapshot is stored, the MAC indicates this to the host with an interrupt. The value of the snapshot is read through a FIFO register access. If the FIFO becomes full and an external trigger to take the snapshot is asserted, then a snapshot trigger-missed status (`ATSSTM`) is set in Register 458 (Timestamp Status Register). This indicates that the latest auxiliary snapshot of the timestamp was not stored in the FIFO. The latest snapshot is not written to the FIFO when it is full. When a host reads the 64-bit timestamp from the FIFO, the space becomes available to store the next snapshot. You can clear a FIFO by setting Bit 19

(ATSFC) in Register 448 (Timestamp Control Register). When multiple snapshots are present in the FIFO, the count is indicated in Bits [27:25], ATSNS, of Register 458 (Timestamp Status Register). †

IEEE 802.3az Energy Efficient Ethernet

Energy Efficient Ethernet (EEE) standardized by IEEE 802.3-az, version D2.0 is supported by the EMAC. It is supported by the MAC operating in 10/100/1000 Mbps rates. EEE is only supported when the EMAC is configured to operate with the RGMII PHY interface operating in full-duplex mode. It cannot be used in half-duplex mode.

EEE enables the MAC to operate in Low-Power Idle (LPI) mode. Either end point of an Ethernet link can disable functionality to save power during periods of low link utilization. The MAC controls whether the system should enter or exit LPI mode and communicates this information to the PHY.†

Related Information

http://www.ieee802.org/3/

For details about the *IEEE 802.3az Energy Efficient Ethernet standard*, refer to the IEEE 802.3 Ethernet Working Group website.†

LPI Timers

Two timers internal to the EMAC are associated with LPI mode:

- LPI Link Status (LS) Timer†
- LPI Time Wait (TW) Timer†

The LPI LS timer counts, in ms, the time expired since the link status has come up. This timer is cleared every time the link goes down and is incremented when the link is up again and the terminal count as programmed by the software is reached. The PHY interface does not assert the LPI pattern unless the terminal count is reached. This protocol ensures a minimum time for which no LPI pattern is asserted after a link is established with the remote station. This period is defined as one second in the IEEE standard 802.3-az, version D2.0. The LPI LS timer is 10 bits wide, so the software can program up to 1023 ms.†

The LPI TW timer counts, in µs, the time expired since the deassertion of LPI. The terminal count of the timer is the value of resolved transmit TW that is the auto-negotiated time after which the MAC can resume the normal transmit operation. The LPI TW timer is 16 bits wide, so the software can program up to 65535 µs.†

The EMAC generates the LPI interrupt when the transmit or receive channel enters or exits the LPI state.†

Checksum Offload

Communication protocols such as TCP and UDP implement checksum fields, which help determine the integrity of data transmitted over a network. Because the most widespread use of Ethernet is to encapsulate TCP and UDP over IP datagrams, the EMAC has a Checksum Offload Engine (COE) to support checksum calculation and insertion in the transmit path, and error detection in the receive path. Supported offloading types:

- Transmit IP header checksum†
- Transmit TCP/UDP/ICMP checksum†
- Receive IP header checksum†
- Receive full checksum†

Frame Filtering

The EMAC implements the following types of filtering for receive frames.

Source Address or Destination Address Filtering

The Address Filtering Module checks the destination and source address field of each incoming packet.†

Unicast Destination Address Filter

Up to 128 MAC addresses for unicast perfect filtering are supported. The filter compares all 48 bits of the received unicast address with the programmed MAC address for any match. Default MacAddr0 is always enabled, other addresses MacAddr1–MacAddr127 are selected with an individual enable bit. For MacAddr1–MacAddr31 addresses, you can mask each byte during comparison with the corresponding received DA byte. This enables group address filtering for the DA. The MacAddr32-MacAddr127 addresses do not have mask control and all six bytes of the MAC address are compared with the received six bytes of DA.†

In hash filtering mode, the filter performs imperfect filtering for unicast addresses using a 256-bit hash table. It uses the upper ten bits of the CRC of the received destination address to index the content of the hash table. A value of 0 selects Bit 0 of the selected register, and a value of 111111 binary selects Bit 63 of the Hash Table register. If the corresponding bit is set to one, the unicast frame is said to have passed the hash filter; otherwise, the frame has failed the hash filter.†

Multicast Destination Address Filter

The MAC can be programmed to pass all multicast frames. In Perfect Filtering mode, the multicast address is compared with the programmed MAC Destination Address registers (1–31). Group address filtering is also supported. In hash filtering mode, the filter performs imperfect filtering using a 256-bit hash table. For hash filtering, it uses the upper ten bits of the CRC of the received multicast address to index the contents of the hash table. A value of 0 selects Bit 0 of the selected register and a value of 111111 binary selects Bit 63 of the Hash Table register. If the corresponding bit is set to one, then the multicast frame is said to have passed the hash filter; otherwise, the frame has failed the hash filter.†

Hash or Perfect Address Filter

The filter can be configured to pass a frame when its DA matches either the hash filter or the Perfect filter. This configuration applies to both unicast and multicast frames.†

Broadcast Address Filter

The filter does not filter any broadcast frames in the default mode. However, if the MAC is programmed to reject all broadcast frames, the filter drops any broadcast frame.†

Unicast Source Address Filter

The MAC can also perform a perfect filtering based on the source address field of the received frames. Group filtering with SA is also supported. You can filter a group of addresses by masking one or more bytes of the address.†

Inverse Filtering Operation (Invert the Filter Match Result at Final Output)

For both Destination and Source address filtering, there is an option to invert the filter-match result at the final output. The result of the unicast or multicast destination address filter is inverted in this mode.†

Destination and Source Address Filtering Summary

The tables below summarize the destination and source address filtering based on the type of frames received and the configuration of bits within the Mac_Frame_Filter register.†

Table 17-19: Destination Address Filtering†

Frame Type	PR	HPF	HUC	DAIF	HMC	PM	DBF	Destination Address Filter Operation
Broadcast	1	X	X	X	X	X	X	Pass
	0	X	X	X	X	X	0	Pass
	0	X	X	X	X	X	1	Fail
Unicast	1	X	X	X	X	X	X	Pass all frames
	0	X	0	0	X	X	X	Pass on Perfect/Group filter match
	0	X	0	1	X	X	X	Fail on Perfrect/Group filter match
	0	0	1	0	X	X	X	Pass on Hash filter match
	0	0	1	1	X	X	X	Fail on Hash filter match
	0	1	1	0	X	X	X	Pass on Hash or Perfect/Group filter match
	0	1	1	1	X	X	X	Fail on Hash or Perfect/Group filter match
Multicast	1	X	X	X	X	X	X	Pass all frames
	X	X	X	X	X	1	X	Pass all frames
	0	X	X	0	0	0	X	Pass on Perfect/Group filter match and drop Pause frames if PCF= 0X
	0	0	X	0	1	0	X	Pass on Hash filter match and drop Pause frames if PCF = 0X
	0	1	X	0	1	0	X	Pass on Hash or Perfect/Group filter match and drop Pause frames if PCF = 0X
	0	X	X	1	0	0	X	Fail on Perfect/Group filter match and drop Pause frames if PCF=0X
	0	0	X	1	1	0	X	Fail on Hash filter match and drop Paus frames if PCF = 0X
	0	1	X	1	1	0	X	Fail Hash on Perfect/Group filter match and drop Pause frames if PCF = 0X

Table 17-20: Source Address Filtering†

Frame Type	PR	DAIF	DBF	Source Address Filter Operation
Unicast	1	X	X	Pass all frames
	0	0	0	Pass status on Perfect or Group filter match but do not drop frames that fail.
	0	1	0	Fail on Perfect or Group filter match but do not drop frame
	0	0	1	Pass on Perfect or Group filter match and drop frames that fail
	0	1	1	Fail on Perfect or Group filter match and drop frames that fail

VLAN Filtering

The EMAC supports the two kinds of VLAN filtering:

- VLAN tag-based filtering†
- VLAN hash filtering†

VLAN Tag-Based Filtering

In the VLAN tag-based frame filtering, the MAC compares the VLAN tag of the received frame and provides the VLAN frame status to the application. Based on the programmed mode, the MAC compares the lower 12 bits or all 16 bits of the received VLAN tag to determine the perfect match. If VLAN tag filtering is enabled, the MAC forwards the VLAN-tagged frames along with VLAN tag match status and drops the VLAN frames that do not match. You can also enable the inverse matching for VLAN frames. In addition, you can enable matching of SVLAN tagged frames along with the default Customer Virtual Local Area Network (C-VLAN) tagged frames.†

VLAN Hash Filtering with a 16-Bit Hash Table

The MAC provides VLAN hash filtering with a 16-bit hash table. The MAC also supports the inverse matching of the VLAN frames. In inverse matching mode, when the VLAN tag of a frame matches the perfect or hash filter, the packet should be dropped. If the VLAN perfect and VLAN hash match are enabled, a frame is considered as matched if either the VLAN hash or the VLAN perfect filter matches. When inverse match is set, a packet is forwarded only when both perfect and hash filters indicate mismatch.†

Layer 3 and Layer 4 Filters

Layer 3 filtering refers to source address and destination address filtering. Layer 4 filtering refers to source port and destination port filtering. The frames are filtered in the following ways:†

- Matched frames†
- Unmatched frames†
- Non-TCP or UDP IP frames†

Matched Frames

The MAC forwards the frames, which match all enabled fields, to the application along with the status. The MAC gives the matched field status only if one of the following conditions is true:†

- All enabled Layer 3 and Layer 4 fields match.†
- At least one of the enabled field matches and other fields are bypassed or disabled.†

Using the CSR set, you can define up to four filters, identified as filter 0 through filter 3. When multiple Layer 3 and Layer 4 filters are enabled, any filter match is considered as a match. If more than one filter matches, the MAC provides status of the lowest filter with filter 0 being the lowest and filter 3 being the highest. For example, if filter 0 and filter 1 match, the MAC gives the status corresponding to filter 0.†

Unmatched Frames

The MAC drops the frames that do not match any of the enabled fields. You can use the inverse match feature to block or drop a frame with specific TCP or UDP over IP fields and forward all other frames. You can configure the EMAC so that when a frame is dropped, it receives a partial frame with appropriate abort status or drops it completely.†

NonTCP or UDP IP Frames

By default, all non-TCP or UDP IP frames are bypassed from the Layer 3 and Layer 4 filters. You can optionally program the MAC to drop all non-TCP or UDP over IP frames.†

Clocks and Resets

Clock Structure

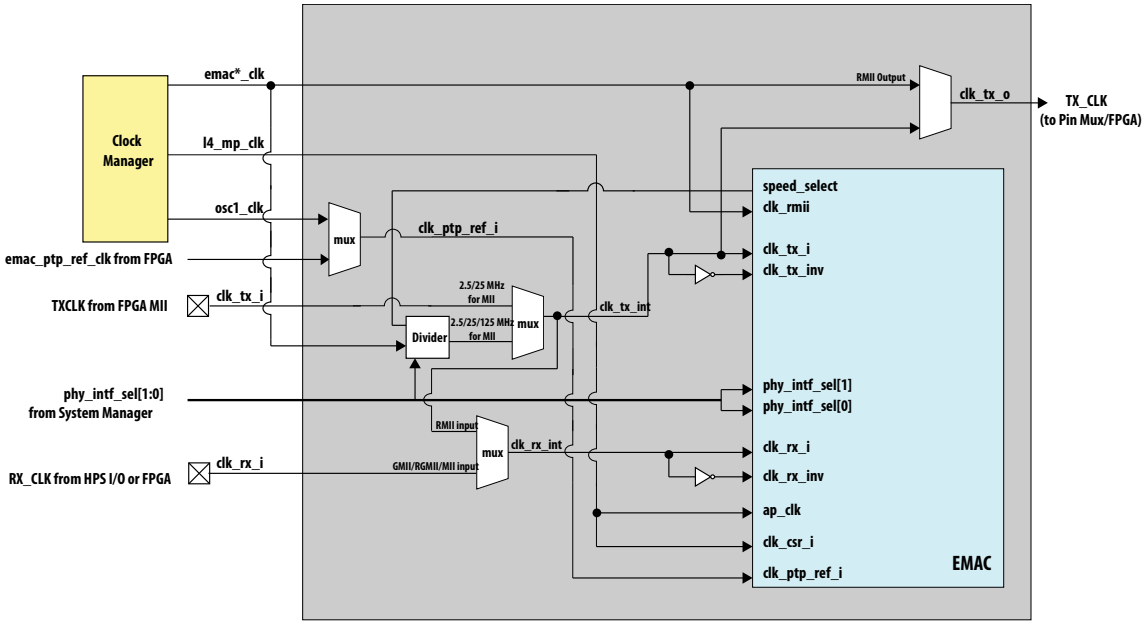
The Ethernet Controller received five input clocks and generates one output clock.

The EMAC controller provides the clock division and muxing necessary to generate the proper clocks for each of the PHY modes and data rates. The clock domains to the Ethernet controller are as follows

- l4_mp_clk clock
- EMAC RX clock
- EMAC TX clock
- clk_ptp_ref

The diagram below summarizes the clock domains of the EMAC module:

Figure 17-15: EMAC Clock Diagram



Clock Gating for EEE

For the RGMII PHY interface, you can gate the transmit clock for Energy Efficient Ethernet (EEE) applications.

Related Information

Programming Guidelines for Energy Efficient Ethernet on page 17-63

Reset

The EMAC module accepts a single reset input, `emac_rst_n`, which is active low.

Note: In all modes, the EMAC core depends on the PHY clocks to be active for the internal EMAC clock sources to be valid.

Taking the Ethernet MAC Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the MPU boots up, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

Interrupts

Interrupts are generated as a result of specific events in the EMAC and external PHY device. The interrupt status register indicates all conditions which may trigger an interrupt and the interrupt enable register determines which interrupts can propagate.

Ethernet MAC Programming Model

The initialization and configuration of the EMAC and its interface is a multi-step process that includes system register programming in the System Manager and Clock Manager and configuration of clocks in multiple domains.

Note: When the EMAC interfaces to HPS I/O and register content is being transferred to a different clock domain after a write operation, no further writes should occur to the same location until the first write is updated. Otherwise, the second write operation does not get updated to the destination clock domain. Thus, the delay between two writes to the same register location should be at least 4 cycles of the destination clock (PHY receive clock, PHY transmit clock, or PTP clock).† If the CSR is accessed multiple times quickly, you must ensure that a minimum number of destination clock cycles have occurred between accesses.

Note: When using the EMAC with signals routed through the FPGA fabric, the minimum time required between two write accesses to the same register is 10 TX clock cycles.

.

System Level EMAC Configuration Registers

In addition to the registers in the Ethernet Controller, there are other system level registers in the Clock Manager, System Manager and Reset Manager that must be programmed in order to configure the EMAC and its interfaces.

The following table gives a summary of the important System Manager clock register bits that control operation of the EMAC. These register bits are static signals that must be set while the corresponding EMAC is in reset.

Table 17-21: System Manager Clock and Interface Settings

Register.Field	Description
`ctrl.ptpclksel_0` `ctrl.ptpclksel_1`	1588 PTP reference clock. This bit selects the soure of the 1588 PTP reference clock. • 0x0= `osc1_clk` (default from Clock Manager) • 0x1= `fpga_ptp_ref_clk` (from FPGA fabric; in this case, the FPGA must be in usermode with an active reference clock)
`ctrl.physel_0` `ctrl.physel_1`	PHY Interface Select. These two bits set the PHY mode. • 0x0= GMII or MII • 0x1= RGMII • 0x2= RMII (default) **Note:** Selecting the 0x0 encoding routes the GMII/MII signals to the FPGA fabric only and selecting the 0x1 encoding routes the RGMII signals to the HPS only.

The following table summarizes the important System Manager configuration register bits. All of the fields, except the AXI cache settings, are assumed to be static and must be set before the EMAC is brought out of reset. If the FPGA interface is used, the FPGA must be in user mode and enabled with the appropriate clock signals active before the EMAC can be brought out of reset.

Table 17-22: System Manager Static Control Settings

Register.Field	Description
module.emac_0 module.emac_1	FPGA interface to EMAC disable. This field is used to disable signals from the FPGA to the EMAC modules that could potentially interfere with their normal operation • 0x0= Disable (default) • 0x1=Enable
l3master.awcache_1 l3master.awcache_0 l3master.arcache_1 l3master.arcache_0	EMAC AXI Master AxCACHE settings. It is recommended that these bits are set while the EMAC is idle or in reset.

Various registers within the Clock Manager must also be configured in order for the EMAC controller to perform properly.

Table 17-23: Clock Manager Settings

Register.Field	Description
emac0clk.cnt emac1clk.cnt	EMAC clock control. The cnt value in this register is used to divide the PLL VCO frequency to generate emac0clk and emac1clk.
en.emac0clk en.emac1clk	emac0clk and emac1clk output enable.

EMAC FPGA Interface Initialization

To initialize the Ethernet controller to use the FPGA GMII/MII interface, specific software steps must be followed.

In general, the FPGA interface must be active in user mode with valid PHY clocks, the Ethernet Controller must be in a reset state during static configuration and the clock must be active and valid before the Ethernet Controller is brought out of reset.

1. After the HPS is released from cold or warm reset, reset the Ethernet Controller module by setting the appropriate emac bit in the permodrst register in the Reset Manager.
2. Configure the EMAC Controller clock to 250 MHz by programming the appropriate cnt value in the emac*clk register in the Clock Manager.
3. Bring the Ethernet PHY out of reset to verify that there are RX PHY clocks.
4. If the PTP clock source is from the FPGA, ensure that the FPGA f2s_ptp_ref_clk is active.

5. The soft GMII/MII adaptor must be loaded with active clocks propagating. The FPGA must be configured to user mode and a reset to the user soft FPGA IP may be required to propagate the PHY clocks to the HPS.
6. Once all clock sources are valid, apply the following clock settings:
   a. Program the `physel_*` field in the `ctrl` register of the System Manager (EMAC Group) to 0x0 to select the GMII/MII PHY interface.
   b. If the PTP clock source is from the FPGA, set the `ptpclksel_*` bit in the `ctrl` register (EMAC group) of the System Manager to be 0x1.
   c. Enable the Ethernet Controller FPGA interface by setting the `emac_*` bit in the `module` register of the System Manager (FPGA Interface group).
7. Configure all of the EMAC static settings if the user requires a different setting from the default value. These settings include AXI AxCache signal values which are programmed in `l3 register` in the EMAC group of the System Manager.
8. Execute a register read back to confirm the clock and static configuration settings are valid.
9. After confirming the settings are valid, software can clear the `emac` bit in the `permodrst` register of the Reset Manager to bring the EMAC out of reset.

When these steps are completed, general Ethernet controller and DMA software initialization and configuration can continue.

Note: These same steps can be applied to convert the HPS GMII to an RGMII, RMII or SGMII interface through the FPGA, except that in step 5 during FPGA configuration, you would load the appropriate soft adaptor for the interface and apply reset to it as well. The PHY interface select encoding would remain as 0x0. For the SGMII interface additional external transceiver logic would be required. Routing the Ethernet signals through the FPGA is useful for designs that are pin-limited in the HPS.

EMAC HPS Interface Initialization

To initialize the Ethernet controller to use the HPS interface, specific software steps must be followed including selecting the correct PHY interface through the System Manager.

In general, the Ethernet Controller must be in a reset state during static configuration and the clock must be active and valid before the Ethernet Controller is brought out of reset.

1. After the HPS is released from cold or warm reset, reset the Ethernet Controller module by setting the appropriate `emac` bit in the `permodrst` register in the Reset Manager.
2. Configure the EMAC Controller clock to 250 MHz by programming the appropriate `cnt` value in the `emac*clk` register in the Clock Manager.
3. Bring the Ethernet PHY out of reset to verify that there are RX PHY clocks.
4. When all the clocks are valid, program the following clock settings:
   a. Set the `physel_*` field in the `ctrl` register of the System Manager (EMAC Group) to 0x1 to select the RGMII PHY interface.
   b. Disable the Ethernet Controller FPGA interfaces by clearing the `emac_*` bit in the `module` register of the System Manager (FPGA Interface group).

5. Configure all of the EMAC static settings if the user requires a different setting from the default value. These settings include AXI AxCache signal values, which are programmed in `l3 register` in the EMAC group of the System Manager.
6. Execute a register read back to confirm the clock and static configuration settings are valid.
7. After confirming the settings are valid, software can clear the `emac` bit in the `permodrst` register of the Reset Manager to bring the EMAC out of reset..

When these steps are completed, general Ethernet controller and DMA software initialization and configuration can continue.

DMA Initialization

This section provides the instructions for initializing the DMA registers in the proper sequence. This initialization sequence can be done after the EMAC interface initialization has been completed. Perform the following steps to initialize the DMA:

1. Provide a software reset to reset all of the EMAC internal registers and logic. (DMA Register 0 (Bus Mode Register) – bit 0). †
2. Wait for the completion of the reset process (poll bit 0 of the DMA Register 0 (Bus Mode Register), which is only cleared after the reset operation is completed). †
3. Poll the bits of Register 11 (AHB or AXI Status) to confirm that all previously initiated (before software reset) or ongoing transactions are complete.

   Note: If the application cannot poll the register after soft reset (because of performance reasons), then it is recommended that you continue with the next steps and check this register again (as mentioned in **12** on page 1-62) before triggering the DMA operations.†
4. Program the following fields to initialize the Bus Mode Register by setting values in DMA Register 0 (Bus Mode Register):†

   - Mixed Burst and AAL
   - Fixed burst or undefined burst†
   - Burst length values and burst mode values†
   - Descriptor Length (only valid if Ring Mode is used)†
   - TX and RX DMA Arbitration scheme†
5. Program the interface options in Register 10 (AXI Bus Mode Register). If fixed burst-length is enabled, then select the maximum burst-length possible on the bus (bits[7:1]).†
6. Create a proper descriptor chain for transmit and receive. In addition, ensure that the receive descriptors are owned by DMA (bit 31 of descriptor should be set). When OSF mode is used, at least two descriptors are required.
7. Make sure that your software creates three or more different transmit or receive descriptors in the chain before reusing any of the descriptors.†
8. Initialize receive and transmit descriptor list address with the base address of the transmit and receive descriptor (Register 3 (Receive Descriptor List Address Register) and Register 4 (Transmit Descriptor List Address Register) respectively).†
9. Program the following fields to initialize the mode of operation in Register 6 (Operation Mode Register):

- Receive and Transmit Store And Forward†
- Receive and Transmit Threshold Control (RTC and TTC)†
- Hardware Flow Control enable†
- Flow Control Activation and De-activation thresholds for MTL Receive and Transmit FIFO buffers (RFA and RFD)†
- Error frame and undersized good frame forwarding enable†
- OSF Mode†

10. Clear the interrupt requests, by writing to those bits of the status register (interrupt bits only) that are set. For example, by writing 1 into bit 16, the normal interrupt summary clears this bit (DMA Register 5 (Status Register)).†
11. Enable the interrupts by programming Register 7 (Interrupt Enable Register).†

    Note: Perform **12** on page 1-62 only if you did not perform **3** on page 1-61.†
12. Read Register 11 (AHB or AXI Status) to confirm that all previous transactions are complete.†

    Note: If any previous transaction is still in progress when you read the Register 11 (AHB or AXI Status), then it is strongly recommended to check the slave components addressed by the master interface.†
13. Start the receive and transmit DMA by setting SR (bit 1) and ST (bit 13) of the control register (DMA Register 6 (Operation Mode Register). †

Detailed bit map of the descriptor structure

EMAC Initialization and Configuration

The following EMAC configuration operations can be performed after DMA initialization. If the EMAC initialization and configuration is done before the DMA is set up, then enable the MAC receiver (last step below) only after the DMA is active. Otherwise, received frames fill the RX FIFO buffer and overflow.

1. Program the EMAC Register 4 (GMII Address Register) for controlling the management cycles for the external PHY. Bits[15:11] of the GMII Address Register are written with the Physical Layer Address of the PHY before reading or writing. Bit 0 indicates if the PHY is busy and is set before reading or writing to the PHY management interface. †
2. Read the 16-bit data of Register 5 (GMII Data Register) from the PHY for link up, speed of operation, and mode of operation, by specifying the appropriate address value in bits 15-11 of Register 4 (GMII Address Register). †
3. Provide the MAC address registers (Register 16 (MAC Address0 High Register) and Register 17 (MAC Address0 Low Register)). Because 128 MAC addresses are supported, you must program the MAC addresses accordingly.
4. Program Register 2 (Hash Table High Register) and Register 3 (Hash Table Low Register).
5. Program the following fields to set the appropriate filters for the incoming frames in Register 1 (MAC Frame Filter): †

    - Receive All †
    - Promiscuous mode †
    - Hash or Perfect Filter †
    - Unicast, multicast, broadcast, and control frames filter settings †
6. Program the following fields for proper flow control in Register 6 (Flow Control Register): †

- Pause time and other pause frame control bits †
- Receive and Transmit Flow control bits †
- Flow Control Busy/Backpressure Activate †

7. Program the Interrupt Mask register bits, as required and if applicable for your configuration. †
8. Program the appropriate fields in Register 0 (MAC Configuration Register) to configure receive and transmit operation modes. After basic configuration is written, set bit 3 (TE) and bit 2 (RE) in this register to enable the receive and transmit state machines. †

Note: Do not change the configuration (such as duplex mode, speed, port, or loopback) when the EMAC DMA is actively transmitting or receiving. Software should change these parameters only when the EMAC DMA transmitter and receiver are not active.

Performing Normal Receive and Transmit Operation

For normal operation, perform the following steps: †

1. For normal transmit and receive interrupts, read the interrupt status. Then, poll the descriptors, reading the status of the descriptor owned by the Host (either transmit or receive). †
2. Set appropriate values for the descriptors, ensuring that transmit and receive descriptors are owned by the DMA to resume the transmission and reception of data. †
3. If the descriptors are not owned by the DMA (or no descriptor is available), the DMA goes into SUSPEND state. The transmission or reception can be resumed by freeing the descriptors and issuing a poll demand by writing 0 into the TX/RX poll demand registers, (Register 1 (Transmit Poll Demand Register) and Register 2 (Receive Poll Demand Register)). †
4. The values of the current host transmitter or receiver descriptor address pointer can be read for the debug process (Register 18 (Current Host Transmit Descriptor Register) and Register 19 (Current Host Receive Descriptor Register)). †
5. The values of the current host transmit buffer address pointer and receive buffer address pointer can be read for the debug process (Register 20 (Current Host Transmit Buffer Address Register) and Register 21 (Current Host Receive Buffer Address Register)). †

Stopping and Starting Transmission

Perform the following steps to pause the transmission for some time: †

1. Disable the transmit DMA (if applicable), by clearing bit 13 (Start or Stop Transmission Command) of Register 6 (Operation Mode Register). †
2. Wait for any previous frame transmissions to complete. You can check this by reading the appropriate bits of Register 9 (Debug Register). †
3. Disable the EMAC transmitter and EMAC receiver by clearing Bit 3 (TE) and Bit 2 (RE) in Register 0 (MAC Configuration Register). †
4. Disable the receive DMA (if applicable), after making sure that the data in the RX FIFO buffer is transferred to the system memory (by reading Register 9 (Debug Register). †
5. Make sure that both the TX FIFO buffer and RX FIFO buffer are empty. †
6. To re-start the operation, first start the DMA and then enable the EMAC transmitter and receiver. †

Programming Guidelines for Energy Efficient Ethernet

Entering and Exiting the TX LPI Mode

The Energy Efficient Ethernet (EEE) feature is available in the EMAC. To use it, perform the following steps during EMAC initialization:

1. Read the PHY register through the MDIO interface, check if the remote end has the EEE capability, and then negotiate the timer values. †
2. Program the PHY registers through the MDIO interface (including the RX_CLK_stoppable bit that indicates to the PHY whether to stop the RX clock in LPI mode.) †
3. Program Bits[16:5], LST, and Bits[15:0], TWT, in Register 13 (LPI Timers Control Register). †
4. Read the link status of the PHY chip by using the MDIO interface and update Bit 17 (PLS) of Register 12 (LPI Control and Status Register) accordingly. This update should be done whenever the link status in the PHY changes. †
5. Set Bit 16 (LPIEN) of Register 12 (LPI Control and Status Register) to make the MAC enter the LPI state. The MAC enters the LPI mode after completing the transmission in progress and sets Bit 0 (TLPIEN). †

   Note: To make the MAC enter the LPI state only after it completes the transmission of all queued frames in the TX FIFO buffer, you should set Bit 19 (LPITXA) in Register 12 (LPI Control and Status Register). †

   Note: To switch off the transmit clock during the LPI state, use the `sbd_tx_clk_gating_ctrl_o` signal for gating the clock input. †

   Note: To switch off the CSR clock or power to the rest of the system during the LPI state, you should wait for the TLPIEN interrupt of Register 12 (LPI Control and Status Register) to be generated. Restore the clocks before performing step 6 on page 1-64 when you want to come out of the LPI state. †
6. Clear Bit 16 (LPIEN) of Register 12 (LPI Control and Status Register) to bring the MAC out of the LPI state. †

The MAC waits for the time programmed in Bits [15:0], TWT, before setting the TLPIEX interrupt status bit and resuming the transmission. †

Gating Off the CSR Clock in the LPI Mode

You can gate off the CSR clock to save the power when the MAC is in the Low-Power Idle (LPI) mode.†

Gating Off the CSR Clock in the RX LPI Mode

The following operations are performed when the MAC receives the LPI pattern from the PHY. †

1. The MAC RX enters the LPI mode and the RX LPI entry interrupt status [RLPIEN interrupt of Register 12 (`LPI_Control_Status`)] is set. †
2. The interrupt pin (`sbd_intr_o`) is asserted. The `sbd_intr_o` interrupt is cleared when the host reads the Register 12 (LPI_Control_Status). †

After the `sbd_intr_o` interrupt is asserted and the MAC TX is also in the LPI mode, you can gate off the CSR clock. If the MAC TX is not in the LPI mode when you gate off the CSR clock, the events on the MAC transmitter do not get reported or updated in the CSR. †

For restoring the CSR clock, wait for the LPI exit indication from the PHY after which the MAC asserts the LPI exit interrupt on `lpi_intr_o` (synchronous to `clk_rx_i`). The `lpi_intr_o` interrupt is cleared when Register 12 is read. †

Gating Off the CSR Clock in the TX LPI Mode

The following operations are performed when Bit 16 (LPIEN) of Register 12 (LPI Control and Status Register) is set: †

1. The Transmit LPI Entry interrupt (TLPIEN bit of Register 12) is set. †
2. The interrupt pin (`sbd_intr_o`) is asserted. The `sbd_intr_o` interrupt is cleared when the host reads the Register 12. †

After the `sbd_intr_o` interrupt is asserted and the MAC RX is also in the LPI mode, you can gate off the CSR clock. If the MAC RX is not in the LPI mode when you gate off the CSR clock, the events on the MAC receiver do not get reported or updated in the CSR. †

To restore the CSR clock, switch on the CSR clock when the MAC has to come out of the TX LPI mode. †

After the CSR clock is resumed, clear Bit 16 (LPIEN) of Register 12 (LPI Control and Status Register) to bring the MAC out of the LPI mode. †

Programming Guidelines for Flexible Pulse-Per-Second (PPS) Output

Generating a Single Pulse on PPS

To generate single Pulse on PPS: †

1. Program 11 or 10 (for interrupt) in Bits [6:5], TRGTMODSEL, of Register 459 (PPS Control Register) to instruct the MAC to use the Target Time registers (register 455 and 456) for the start time of PPS signal output. †
2. Program the start time value in the Target Time registers (register 455 and 456). †
3. Program the width of the PPS signal output in Register 473 (PPS0 Width Register). †
4. Program Bits [3:0], PPSCMD, of Register 459 (PPS Control Register) to 0001 to instruct the MAC to generate a single pulse on the PPS signal output at the time programmed in the Target Time registers (register 455 and 456). †

Once the PPSCMD is executed (PPSCMD bits = 0), you can cancel the pulse generation by giving the Cancel Start Command (PPSCMD=0011) before the programmed start time elapses. You can also program the behavior of the next pulse in advance. To program the next pulse: †

1. Program the start time for the next pulse in the Target Time registers (register 455 and 456). This time should be more than the time at which the falling edge occurs for the previous pulse. †
2. Program the width of the next PPS signal output in Register 473 (PPS0 Width Register). †
3. Program Bits [3:0], PPSCMD, of Register 459 (PPS Control Register) to generate a single pulse on the PPS signal output after the time at which the previous pulse is de-asserted. And at the time programmed in Target Time registers. If you give this command before the previous pulse becomes low, then the new command overwrites the previous command and the EMAC may generate only 1 extended pulse.

Generating a Pulse Train on PPS

To generate a pulse train on PPS: †

1. Program 11 or 10 (for an interrupt) in Bits [6:5], TRGTMODSEL, of Register 459 (PPS Control Register) to instruct the MAC to use the Target Time registers (register 455 and 456) for the start time of the PPS signal output. †
2. Program the start time value in the Target Time registers (register 455 and 456). †
3. Program the interval value between the train of pulses on the PPS signal output in Register 473 (PPS0 Width Register). †
4. Program the width of the PPS signal output in Register 473 (PPS0 Width Register). †
5. Program Bits[3:0], PPSCMD, of Register 459 (PPS Control Register) to 0010 to instruct the MAC to generate a train of pulses on the PPS signal output with the start time programmed in the Target Time registers (register 455 and 456). By default, the PPS pulse train is free-running unless stopped by 'STOP Pulse train at time' or 'STOP Pulse Train immediately' commands. †
6. Program the stop value in the Target Time registers (register 455 and 456). Ensure that Bit 31 (TSTRBUSY) of Register 456 (Target Time Nanoseconds Register) is clear before programming the Target Time registers (register 455 and 456) again. †
7. Program the PPSCMD field (bit 3:0) of Register 459 (PPS Control Register) to 0100 to stop the train of pulses on the PPS signal output after the programmed stop time specified in step 6 on page 1-66 elapses. †

You can stop the pulse train at any time by programming 0101 in the PPSCMD field. Similarly, you can cancel the Stop Pulse train command (given in step 7 on page 1-66) by programming 0110 in the PPSCMD field before the time (programmed in step 6 on page 1-66) elapses. You can cancel the pulse train generation by programming 0011 in the PPSCMD field before the programmed start time (in step 2 on page 1-66) elapses. †

Generating an Interrupt without Affecting the PPS

Bits [6:5], TRGTMODSEL, of Register 459 (PPS Control Register) enable you to program the Target Time registers (register 455 and 456) to do any one of the following: †

- Generate only interrupts. †
- Generate interrupts and the PPS start and stop time. †
- Generate only PPS start and stop time. †

To program the Target Time registers (register 455 and 456) to generate only interrupt events: †

1. Program 00 (for interrupt) in Bits [6:5], TRGTMODSEL, of Register 459 (PPS Control Register) to instruct the MAC to use the Target Time registers (register 455 and 456) for the target time interrupt. †
2. Program a target time value in the Target Time registers (register 455 and 456) to instruct the MAC to generate an interrupt when the target time elapses. If Bits [6:5], TRGTMODSEL, are changed (for example, to control the PPS), then the interrupt generation is overwritten with the new mode and new programmed Target Time register value.

Ethernet MAC Address Map and Register Definitions

The address map and register definitions for the HPS-FPGA bridges consist of the following regions:

- EMAC Module 0
- EMAC Module 1

GMAC Register Group Register Descriptions

GMAC Register Group

Offset: 0x0

MAC_Configuration on page 17-132
The MAC Configuration register establishes receive and transmit operating modes.

MAC_Frame_Filter on page 17-139
The MAC Frame Filter register contains the filter controls for receiving frames. Some of the controls from this register go to the address check block of the MAC, which performs the first level of address filtering. The second level of filtering is performed on the incoming frame, based on other controls such as Pass Bad Frames and Pass Control Frames.

GMII_Address on page 17-145
The GMII Address register controls the management cycles to the external PHY through the management interface.

GMII_Data on page 17-147
The GMII Data register stores Write data to be written to the PHY register located at the address specified in Register 4 (GMII Address Register). This register also stores the Read data from the PHY register located at the address specified by Register 4.

Flow_Control on page 17-148
The Flow Control register controls the generation and reception of the Control (Pause Command) frames by the MAC's Flow control block. A Write to a register with the Busy bit set to '1' triggers the Flow Control block to generate a Pause Control frame. The fields of the control frame are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control frame. The Busy bit remains set until the control frame is transferred onto the cable. The Host must make sure that the Busy bit is cleared before writing to the register.

VLAN_Tag on page 17-151
The VLAN Tag register contains the IEEE 802.1Q VLAN Tag to identify the VLAN frames. The MAC compares the 13th and 14th bytes of the receiving frame (Length/Type) with 16'h8100, and the following two bytes are compared with the VLAN tag. If a match occurs, the MAC sets the received VLAN bit in the receive frame status. The legal length of the frame is increased from 1,518 bytes to 1,522 bytes. Because the VLAN Tag register is double-synchronized to the (G)MII clock domain, then consecutive writes to these register should be performed only after at least four clock cycles in the destination clock domain.

Version on page 17-153
The Version registers identifies the version of the EMAC. This register contains two bytes: one specified by Synopsys to identify the core release number, and the other specified by Altera.

Debug on page 17-153
The Debug register gives the status of all main blocks of the transmit and receive data-paths and the FIFOs. An all-zero status indicates that the MAC is in idle state (and FIFOs are empty) and no activity is going on in the data-paths.

LPI_Control_Status on page 17-157
The LPI Control and Status Register controls the LPI functions and provides the LPI interrupt status. The status bits are cleared when this register is read.

LPI_Timers_Control on page 17-160
The LPI Timers Control register controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.

Interrupt_Status on page 17-161
The Interrupt Status register identifies the events in the MAC that can generate interrupt. All interrupt events are generated only when the corresponding optional feature is enabled.

Interrupt_Mask on page 17-164
The Interrupt Mask Register bits enable you to mask the interrupt signal because of the corresponding event in the Interrupt Status Register. The interrupt signal is sbd_intr_o.

MAC_Address0_High on page 17-165
The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the (G)MII interface corresponds to the LS byte (Bits [7:0]) of the MAC Address Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the (G)MII as the destination address, then the MacAddress0 Register [47:0] is compared with 0x665544332211. Because the MAC address registers are double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address0 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

MAC_Address0_Low on page 17-166
The MAC Address0 Low register holds the lower 32 bits of the first 6-byte MAC address of the station.

MAC_Address1_High on page 17-167
The MAC Address1 High register holds the upper 16 bits of the 2nd 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address1 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address1_Low on page 17-170
The MAC Address1 Low register holds the lower 32 bits of the 2nd 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address2_High on page 17-171
The MAC Address2 High register holds the upper 16 bits of the 3rd 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address2 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address2_Low on page 17-174
The MAC Address2 Low register holds the lower 32 bits of the 3rd 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address3_High on page 17-175
The MAC Address3 High register holds the upper 16 bits of the 4th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address3 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address3_Low on page 17-178
The MAC Address3 Low register holds the lower 32 bits of the 4th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address4_High on page 17-179
The MAC Address4 High register holds the upper 16 bits of the 5th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address4 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address4_Low on page 17-182
The MAC Address4 Low register holds the lower 32 bits of the 5th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address5_High on page 17-183
The MAC Address5 High register holds the upper 16 bits of the 6th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address5 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address5_Low on page 17-186
The MAC Address5 Low register holds the lower 32 bits of the 6th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address6_High on page 17-187
The MAC Address6 High register holds the upper 16 bits of the 7th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address6 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address6_Low on page 17-190
The MAC Address6 Low register holds the lower 32 bits of the 7th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address7_High on page 17-191
The MAC Address7 High register holds the upper 16 bits of the 8th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address7 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address7_Low on page 17-194
The MAC Address7 Low register holds the lower 32 bits of the 8th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address8_High on page 17-195
The MAC Address8 High register holds the upper 16 bits of the 9th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address8 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address8_Low on page 17-198
The MAC Address8 Low register holds the lower 32 bits of the 9th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address9_High on page 17-199
The MAC Address9 High register holds the upper 16 bits of the 10th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address9 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address9_Low on page 17-202
The MAC Address9 Low register holds the lower 32 bits of the 10th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address10_High on page 17-203
The MAC Address10 High register holds the upper 16 bits of the 11th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address10 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address10_Low on page 17-206
The MAC Address10 Low register holds the lower 32 bits of the 11th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address11_High on page 17-207
The MAC Address11 High register holds the upper 16 bits of the 12th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address11 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address11_Low on page 17-210
The MAC Address11 Low register holds the lower 32 bits of the 12th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address12_High on page 17-211
The MAC Address12 High register holds the upper 16 bits of the 13th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address12 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address12_Low on page 17-214
The MAC Address12 Low register holds the lower 32 bits of the 13th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address13_High on page 17-215
The MAC Address13 High register holds the upper 16 bits of the 14th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address13 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address13_Low on page 17-218
The MAC Address13 Low register holds the lower 32 bits of the 14th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address14_High on page 17-219
The MAC Address14 High register holds the upper 16 bits of the 15th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address14 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address14_Low on page 17-222
The MAC Address14 Low register holds the lower 32 bits of the 15th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address15_High on page 17-223
The MAC Address15 High register holds the upper 16 bits of the 16th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address15 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MMC_IPC_Receive_Interrupt on page 17-290
This register maintains the interrupts generated when receive IPC statistic counters reach half their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Checksum Offload Interrupt register is 32-bits wide. When the MMC IPC counter that caused the interrupt is read, its corresponding interrupt bit is cleared. The counter's least-significant byte lane (bits[7:0]) must be read to clear the interrupt bit.

rxipv4_gd_frms on page 17-296
Number of good IPv4 datagrams received with the TCP, UDP, or ICMP payload

rxipv4_hdrerr_frms on page 17-297
Number of IPv4 datagrams received with header (checksum, length, or version mismatch) errors

rxipv4_nopay_frms on page 17-297
Number of IPv4 datagram frames received that did not have a TCP, UDP, or ICMP payload processed by the Checksum engine

rxipv4_frag_frms on page 17-298
Number of good IPv4 datagrams with fragmentation

rxipv4_udsbl_frms on page 17-298
Number of good IPv4 datagrams received that had a UDP payload with checksum disabled

rxipv6_gd_frms on page 17-299
Number of good IPv6 datagrams received with TCP, UDP, or ICMP payloads

rxipv6_hdrerr_frms on page 17-300
Number of IPv6 datagrams received with header errors (length or version mismatch)

rxipv6_nopay_frms on page 17-300
Number of IPv6 datagram frames received that did not have a TCP, UDP, or ICMP payload. This includes all IPv6 datagrams with fragmentation or security extension headers

rxudp_gd_frms on page 17-301
Number of good IP datagrams with a good UDP payload. This counter is not updated when the counter is incremented

rxudp_err_frms on page 17-301
Number of good IP datagrams whose UDP payload has a checksum error

rxtcp_gd_frms on page 17-302
Number of good IP datagrams with a good TCP payload

rxtcp_err_frms on page 17-302
Number of good IP datagrams whose TCP payload has a checksum error

rxicmp_gd_frms on page 17-303
Number of good IP datagrams with a good ICMP payload

rxicmp_err_frms on page 17-304
Number of good IP datagrams whose ICMP payload has a checksum error

rxipv4_gd_octets on page 17-304
Number of bytes received in good IPv4 datagrams encapsulating TCP, UDP, or ICMP data

rxipv4_hdrerr_octets on page 17-305
Number of bytes received in IPv4 datagrams with header errors (checksum, length, version mismatch). The value in the Length field of IPv4 header is used to update this counter

rxipv4_nopay_octets on page 17-305
Number of bytes received in IPv4 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the IPv4 headers Length field is used to update this counter

rxipv4_frag_octets on page 17-306
Number of bytes received in fragmented IPv4 datagrams. The value in the IPv4 headers Length field is used to update this counter

rxipv4_udsbl_octets on page 17-307
Number of bytes received in a UDP segment that had the UDP checksum disabled. This counter does not count IP Header bytes

rxipv6_gd_octets on page 17-307
Number of bytes received in good IPv6 datagrams encapsulating TCP, UDP or ICMPv6 data

rxipv6_hdrerr_octets on page 17-308
Number of bytes received in IPv6 datagrams with header errors (length, version mismatch). The value in the IPv6 headers Length field is used to update this counter

rxipv6_nopay_octets on page 17-308
Number of bytes received in IPv6 datagrams that did not have a TCP, UDP, or ICMP payload. The value in the IPv6 headers Length field is used to update this counter

rxudp_gd_octets on page 17-309
Number of bytes received in a good UDP segment. This counter does not count IP header bytes

rxudp_err_octets on page 17-309
Number of bytes received in a UDP segment that had checksum errors

rxtcp_gd_octets on page 17-310
Number of bytes received in a good TCP segment

rxtcperroctets on page 17-311
Number of bytes received in a TCP segment with checksum errors

rxicmp_gd_octets on page 17-311
Number of bytes received in a good ICMP segment

rxicmp_err_octets on page 17-312
Number of bytes received in an ICMP segment with checksum errors

L3_L4_Control0 on page 17-312
This register controls the operations of the filter 0 of Layer 3 and Layer 4.

Layer4_Address0 on page 17-315
Because the Layer 3 and Layer 4 Address Registers are double-synchronized to the Rx clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform the consecutive writes to the same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

Layer3_Addr0_Reg0 on page 17-316
For IPv4 frames, the Layer 3 Address 0 Register 0 contains the 32-bit IP Source Address field. For IPv6 frames, it contains Bits[31:0] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr1_Reg0 on page 17-317
For IPv4 frames, the Layer 3 Address 1 Register 0 contains the 32-bit IP Destination Address field. For IPv6 frames, it contains Bits[63:32] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr2_Reg0 on page 17-318
For IPv4 frames, the Layer 3 Address 2 Register 0 is reserved. For IPv6 frames, it contains Bits [95:64] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr3_Reg0 on page 17-319
For IPv4 frames, the Layer 3 Address 3 Register 0 is reserved. For IPv6 frames, it contains Bits [127:96] of the 128-bit IP Source Address or Destination Address field.

L3_L4_Control1 on page 17-320
This register controls the operations of the filter 0 of Layer 3 and Layer 4.

Layer4_Address1 on page 17-323
Because the Layer 3 and Layer 4 Address Registers are double-synchronized to the Rx clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform the consecutive writes to the same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

Layer3_Addr0_Reg1 on page 17-324
For IPv4 frames, the Layer 3 Address 0 Register 1 contains the 32-bit IP Source Address field. For IPv6 frames, it contains Bits[31:0] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr1_Reg1 on page 17-324
For IPv4 frames, the Layer 3 Address 1 Register 1 contains the 32-bit IP Destination Address field. For IPv6 frames, it contains Bits[63:32] of the 128-bit IP Source Address or Destination Address field

Layer3_Addr2_Reg1 on page 17-325
For IPv4 frames, the Layer 3 Address 2 Register 1 is reserved. For IPv6 frames, it contains Bits [95:64] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr3_Reg1 on page 17-326
For IPv4 frames, the Layer 3 Address 3 Register 1 is reserved. For IPv6 frames, it contains Bits [127:96] of the 128-bit IP Source Address or Destination Address field.

L3_L4_Control2 on page 17-327
This register controls the operations of the filter 2 of Layer 3 and Layer 4.

Layer4_Address2 on page 17-329
Because the Layer 3 and Layer 4 Address Registers are double-synchronized to the Rx clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform the consecutive writes to the same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

Layer3_Addr0_Reg2 on page 17-330
For IPv4 frames, the Layer 3 Address 0 Register 2 contains the 32-bit IP Source Address field. For IPv6 frames, it contains Bits [31:0] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr1_Reg2 on page 17-331
For IPv4 frames, the Layer 3 Address 1 Register 2 contains the 32-bit IP Destination Address field. For IPv6 frames, it contains Bits [63:32] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr2_Reg2 on page 17-332
For IPv4 frames, the Layer 3 Address 2 Register 2 is reserved. For IPv6 frames, it contains Bits [95:64] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr3_Reg2 on page 17-333
For IPv4 frames, the Layer 3 Address 3 Register 2 is reserved. For IPv6 frames, it contains Bits [127:96] of the 128-bit IP Source Address or Destination Address field.

L3_L4_Control3 on page 17-334
This register controls the operations of the filter 0 of Layer 3 and Layer 4.

Layer4_Address3 on page 17-337
Because the Layer 3 and Layer 4 Address Registers are double-synchronized to the Rx clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform the consecutive writes to the same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

Layer3_Addr0_Reg3 on page 17-338
For IPv4 frames, the Layer 3 Address 0 Register 3 contains the 32-bit IP Source Address field. For IPv6 frames, it contains Bits [31:0] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr1_Reg3 on page 17-338
For IPv4 frames, the Layer 3 Address 1 Register 3 contains the 32-bit IP Destination Address field. For IPv6 frames, it contains Bits [63:32] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr2_Reg3 on page 17-339
For IPv4 frames, the Layer 3 Address 2 Register 3 is reserved. For IPv6 frames, it contains Bits [95:64] of the 128-bit IP Source Address or Destination Address field.

Layer3_Addr3_Reg3 on page 17-340
For IPv4 frames, the Layer 3 Address 3 Register 3 is reserved. For IPv6 frames, it contains Bits [127:96] of the 128-bit IP Source Address or Destination Address field.

Hash_Table_Reg0 on page 17-341
This register contains the first 32 bits of the hash table. The 256-bit Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming frame is passed through the CRC logic and the upper eight bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 8b'10111111 selects Bit 31 of the Hash Table Register 5. The hash value of the destination address is calculated in the following way: 1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32). 2. Perform bitwise reversal for the value obtained in Step 1. 3. Take the upper 8 bits from the value obtained in Step 2. If the corresponding bit value of the register is 1'b1, the frame is accepted. Otherwise, it is rejected. If the Bit 1 (Pass All Multicast) is set in Register 1 (MAC Frame Filter), then all multicast frames are accepted regardless of the multicast hash values. Because the Hash Table register is double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written. Note: Because of double-synchronization, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

MAC_Address16_High on page 17-366
The MAC Address16 High register holds the upper 16 bits of the 17th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address16 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address16_Low on page 17-369
The MAC Address16 Low register holds the lower 32 bits of the 17th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address17_High on page 17-370
The MAC Address17 High register holds the upper 16 bits of the 18th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address17 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address17_Low on page 17-373
The MAC Address17 Low register holds the lower 32 bits of the 18th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address18_High on page 17-374
The MAC Address18 High register holds the upper 16 bits of the 19th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address18 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address18_Low on page 17-377
The MAC Address18 Low register holds the lower 32 bits of the 19th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address19_High on page 17-378
The MAC Address19 High register holds the upper 16 bits of the 20th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address19 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address19_Low on page 17-381
The MAC Address19 Low register holds the lower 32 bits of the 20th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address20_High on page 17-382
The MAC Address20 High register holds the upper 16 bits of the 21th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address20 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address20_Low on page 17-385
The MAC Address20 Low register holds the lower 32 bits of the 21th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address21_High on page 17-386
The MAC Address21 High register holds the upper 16 bits of the 22th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address21 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address21_Low on page 17-389
The MAC Address21 Low register holds the lower 32 bits of the 22th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address22_High on page 17-390
The MAC Address22 High register holds the upper 16 bits of the 23th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address22 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address22_Low on page 17-393
The MAC Address22 Low register holds the lower 32 bits of the 23th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address23_High on page 17-394
The MAC Address23 High register holds the upper 16 bits of the 24th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address23 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address23_Low on page 17-397
The MAC Address23 Low register holds the lower 32 bits of the 24th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address24_High on page 17-398
The MAC Address24 High register holds the upper 16 bits of the 25th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address24 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address24_Low on page 17-401
The MAC Address24 Low register holds the lower 32 bits of the 25th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address25_High on page 17-402
The MAC Address25 High register holds the upper 16 bits of the 26th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address25 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address25_Low on page 17-405
The MAC Address25 Low register holds the lower 32 bits of the 26th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address26_High on page 17-406
The MAC Address26 High register holds the upper 16 bits of the 27th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address26 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address26_Low on page 17-409
The MAC Address26 Low register holds the lower 32 bits of the 27th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address27_High on page 17-410
The MAC Address27 High register holds the upper 16 bits of the 28th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address27 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address27_Low on page 17-413
The MAC Address27 Low register holds the lower 32 bits of the 28th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address28_High on page 17-414
The MAC Address28 High register holds the upper 16 bits of the 29th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address28 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address28_Low on page 17-417
The MAC Address28 Low register holds the lower 32 bits of the 29th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address29_High on page 17-418
The MAC Address29 High register holds the upper 16 bits of the 30th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address29 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address29_Low on page 17-421
The MAC Address29 Low register holds the lower 32 bits of the 30th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address30_High on page 17-422
The MAC Address30 High register holds the upper 16 bits of the 31th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address30 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address30_Low on page 17-425
The MAC Address30 Low register holds the lower 32 bits of the 31th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address31_High on page 17-426
The MAC Address31 High register holds the upper 16 bits of the 32th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address31 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address31_Low on page 17-429
The MAC Address31 Low register holds the lower 32 bits of the 32th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address32_High on page 17-430
The MAC Address32 High register holds the upper 16 bits of the 33th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address32 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address32_Low on page 17-433
The MAC Address32 Low register holds the lower 32 bits of the 33th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address33_High on page 17-434
The MAC Address33 High register holds the upper 16 bits of the 34th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address33 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address33_Low on page 17-437
The MAC Address33 Low register holds the lower 32 bits of the 34th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address34_High on page 17-438
The MAC Address34 High register holds the upper 16 bits of the 35th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address34 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address34_Low on page 17-441
The MAC Address34 Low register holds the lower 32 bits of the 35th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address35_High on page 17-442
The MAC Address35 High register holds the upper 16 bits of the 36th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address35 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address35_Low on page 17-445
The MAC Address35 Low register holds the lower 32 bits of the 36th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address36_High on page 17-446
The MAC Address36 High register holds the upper 16 bits of the 37th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address36 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address36_Low on page 17-449
The MAC Address36 Low register holds the lower 32 bits of the 37th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address37_High on page 17-450
The MAC Address37 High register holds the upper 16 bits of the 38th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address37 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address37_Low on page 17-453
The MAC Address37 Low register holds the lower 32 bits of the 38th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address38_High on page 17-454
The MAC Address38 High register holds the upper 16 bits of the 39th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address38 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address38_Low on page 17-457
The MAC Address38 Low register holds the lower 32 bits of the 39th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address39_High on page 17-458
The MAC Address39 High register holds the upper 16 bits of the 40th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address39 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address39_Low on page 17-461
The MAC Address39 Low register holds the lower 32 bits of the 40th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address40_High on page 17-462
The MAC Address40 High register holds the upper 16 bits of the 41th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address40 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address40_Low on page 17-465
The MAC Address40 Low register holds the lower 32 bits of the 41th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address41_High on page 17-466
The MAC Address41 High register holds the upper 16 bits of the 42th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address41 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address41_Low on page 17-469
The MAC Address41 Low register holds the lower 32 bits of the 42th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address42_High on page 17-470
The MAC Address42 High register holds the upper 16 bits of the 43th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address42 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address42_Low on page 17-473
The MAC Address42 Low register holds the lower 32 bits of the 43th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address43_High on page 17-474
The MAC Address43 High register holds the upper 16 bits of the 44th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address43 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address43_Low on page 17-477
The MAC Address43 Low register holds the lower 32 bits of the 44th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address44_High on page 17-478
The MAC Address44 High register holds the upper 16 bits of the 45th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address44 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address44_Low on page 17-481
The MAC Address44 Low register holds the lower 32 bits of the 45th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address45_High on page 17-482
The MAC Address45 High register holds the upper 16 bits of the 46th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address45 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address45_Low on page 17-485
The MAC Address45 Low register holds the lower 32 bits of the 46th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address46_High on page 17-486
The MAC Address46 High register holds the upper 16 bits of the 47th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address46 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address46_Low on page 17-489
The MAC Address46 Low register holds the lower 32 bits of the 47th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address47_High on page 17-490
The MAC Address47 High register holds the upper 16 bits of the 48th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address47 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address47_Low on page 17-493
The MAC Address47 Low register holds the lower 32 bits of the 48th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address48_High on page 17-494
The MAC Address48 High register holds the upper 16 bits of the 49th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address48 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address48_Low on page 17-497
The MAC Address48 Low register holds the lower 32 bits of the 49th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address49_High on page 17-498
The MAC Address49 High register holds the upper 16 bits of the 50th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address49 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address49_Low on page 17-501
The MAC Address49 Low register holds the lower 32 bits of the 50th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address50_High on page 17-502
The MAC Address50 High register holds the upper 16 bits of the 51th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address50 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address50_Low on page 17-505
The MAC Address50 Low register holds the lower 32 bits of the 51th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address51_High on page 17-506
The MAC Address51 High register holds the upper 16 bits of the 52th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address51 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address51_Low on page 17-509
The MAC Address51 Low register holds the lower 32 bits of the 52th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address52_High on page 17-510
The MAC Address52 High register holds the upper 16 bits of the 53th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address52 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address52_Low on page 17-513
The MAC Address52 Low register holds the lower 32 bits of the 53th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address53_High on page 17-514
The MAC Address53 High register holds the upper 16 bits of the 54th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address53 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address53_Low on page 17-517
The MAC Address53 Low register holds the lower 32 bits of the 54th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address54_High on page 17-518
The MAC Address54 High register holds the upper 16 bits of the 55th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address54 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address54_Low on page 17-521
The MAC Address54 Low register holds the lower 32 bits of the 55th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address55_High on page 17-522
The MAC Address55 High register holds the upper 16 bits of the 56th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address55 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address55_Low on page 17-525
The MAC Address55 Low register holds the lower 32 bits of the 56th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address56_High on page 17-526
The MAC Address56 High register holds the upper 16 bits of the 57th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address56 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address56_Low on page 17-529
The MAC Address56 Low register holds the lower 32 bits of the 57th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address57_High on page 17-530
The MAC Address57 High register holds the upper 16 bits of the 58th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address57 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address57_Low on page 17-533
The MAC Address57 Low register holds the lower 32 bits of the 58th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address58_High on page 17-534
The MAC Address58 High register holds the upper 16 bits of the 59th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address58 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address58_Low on page 17-537
The MAC Address58 Low register holds the lower 32 bits of the 59th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address59_High on page 17-538
The MAC Address59 High register holds the upper 16 bits of the 60th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address59 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address59_Low on page 17-541
The MAC Address59 Low register holds the lower 32 bits of the 60th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address60_High on page 17-542
The MAC Address60 High register holds the upper 16 bits of the 61th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address60 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address60_Low on page 17-545
The MAC Address60 Low register holds the lower 32 bits of the 61th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address61_High on page 17-546
The MAC Address61 High register holds the upper 16 bits of the 62th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address61 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address61_Low on page 17-549
The MAC Address61 Low register holds the lower 32 bits of the 62th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address62_High on page 17-550
The MAC Address62 High register holds the upper 16 bits of the 63th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address62 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address62_Low on page 17-553
The MAC Address62 Low register holds the lower 32 bits of the 63th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address63_High on page 17-554
The MAC Address63 High register holds the upper 16 bits of the 64th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address63 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address63_Low on page 17-557
The MAC Address63 Low register holds the lower 32 bits of the 64th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address64_High on page 17-558
The MAC Address64 High register holds the upper 16 bits of the 65th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address64 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address64_Low on page 17-561
The MAC Address64 Low register holds the lower 32 bits of the 65th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address65_High on page 17-562
The MAC Address65 High register holds the upper 16 bits of the 66th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address65 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address65_Low on page 17-565
The MAC Address65 Low register holds the lower 32 bits of the 66th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address66_High on page 17-566
The MAC Address66 High register holds the upper 16 bits of the 67th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address66 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address66_Low on page 17-569
The MAC Address66 Low register holds the lower 32 bits of the 67th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address67_High on page 17-570
The MAC Address67 High register holds the upper 16 bits of the 68th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address67 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address67_Low on page 17-573
The MAC Address67 Low register holds the lower 32 bits of the 68th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address68_High on page 17-574
The MAC Address68 High register holds the upper 16 bits of the 69th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address68 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address68_Low on page 17-577
The MAC Address68 Low register holds the lower 32 bits of the 69th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address69_High on page 17-578
The MAC Address69 High register holds the upper 16 bits of the 70th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address69 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address69_Low on page 17-581
The MAC Address69 Low register holds the lower 32 bits of the 70th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address70_High on page 17-582
The MAC Address70 High register holds the upper 16 bits of the 71th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address70 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address70_Low on page 17-585
The MAC Address70 Low register holds the lower 32 bits of the 71th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address71_High on page 17-586
The MAC Address71 High register holds the upper 16 bits of the 72th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address71 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address71_Low on page 17-589
The MAC Address71 Low register holds the lower 32 bits of the 72th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address72_High on page 17-590
The MAC Address72 High register holds the upper 16 bits of the 73th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address72 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address72_Low on page 17-593
The MAC Address72 Low register holds the lower 32 bits of the 73th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address73_High on page 17-594
The MAC Address73 High register holds the upper 16 bits of the 74th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address73 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address73_Low on page 17-597
The MAC Address73 Low register holds the lower 32 bits of the 74th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address74_High on page 17-598
The MAC Address74 High register holds the upper 16 bits of the 75th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address74 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address74_Low on page 17-601
The MAC Address74 Low register holds the lower 32 bits of the 75th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address75_High on page 17-602
The MAC Address75 High register holds the upper 16 bits of the 76th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address75 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address75_Low on page 17-605
The MAC Address75 Low register holds the lower 32 bits of the 76th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address76_High on page 17-606
The MAC Address76 High register holds the upper 16 bits of the 77th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address76 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address76_Low on page 17-609
The MAC Address76 Low register holds the lower 32 bits of the 77th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address77_High on page 17-610
The MAC Address77 High register holds the upper 16 bits of the 78th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address77 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address77_Low on page 17-613
The MAC Address77 Low register holds the lower 32 bits of the 78th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address78_High on page 17-614
The MAC Address78 High register holds the upper 16 bits of the 79th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address78 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address78_Low on page 17-617
The MAC Address78 Low register holds the lower 32 bits of the 79th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address79_High on page 17-618
The MAC Address79 High register holds the upper 16 bits of the 80th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address79 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address79_Low on page 17-621
The MAC Address79 Low register holds the lower 32 bits of the 80th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address80_High on page 17-622
The MAC Address80 High register holds the upper 16 bits of the 81th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address80 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address80_Low on page 17-625
The MAC Address80 Low register holds the lower 32 bits of the 81th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address81_High on page 17-626
The MAC Address81 High register holds the upper 16 bits of the 82th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address81 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address81_Low on page 17-629
The MAC Address81 Low register holds the lower 32 bits of the 82th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address82_High on page 17-630
The MAC Address82 High register holds the upper 16 bits of the 83th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address82 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address82_Low on page 17-633
The MAC Address82 Low register holds the lower 32 bits of the 83th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address83_High on page 17-634
The MAC Address83 High register holds the upper 16 bits of the 84th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address83 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address83_Low on page 17-637
The MAC Address83 Low register holds the lower 32 bits of the 84th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address84_High on page 17-638
The MAC Address84 High register holds the upper 16 bits of the 85th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address84 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address84_Low on page 17-641
The MAC Address84 Low register holds the lower 32 bits of the 85th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address85_High on page 17-642
The MAC Address85 High register holds the upper 16 bits of the 86th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address85 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address85_Low on page 17-645
The MAC Address85 Low register holds the lower 32 bits of the 86th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address86_High on page 17-646
The MAC Address86 High register holds the upper 16 bits of the 87th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address86 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address86_Low on page 17-649
The MAC Address86 Low register holds the lower 32 bits of the 87th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address87_High on page 17-650
The MAC Address87 High register holds the upper 16 bits of the 88th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address87 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address87_Low on page 17-653
The MAC Address87 Low register holds the lower 32 bits of the 88th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address88_High on page 17-654
The MAC Address88 High register holds the upper 16 bits of the 89th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address88 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address88_Low on page 17-657
The MAC Address88 Low register holds the lower 32 bits of the 89th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address89_High on page 17-658
The MAC Address89 High register holds the upper 16 bits of the 90th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address89 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address89_Low on page 17-661
The MAC Address89 Low register holds the lower 32 bits of the 90th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address90_High on page 17-662
The MAC Address90 High register holds the upper 16 bits of the 91th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address90 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address90_Low on page 17-665
The MAC Address90 Low register holds the lower 32 bits of the 91th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address91_High on page 17-666
The MAC Address91 High register holds the upper 16 bits of the 92th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address91 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address91_Low on page 17-669
The MAC Address91 Low register holds the lower 32 bits of the 92th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address92_High on page 17-670
The MAC Address92 High register holds the upper 16 bits of the 93th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address92 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address92_Low on page 17-673
The MAC Address92 Low register holds the lower 32 bits of the 93th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address93_High on page 17-674
The MAC Address93 High register holds the upper 16 bits of the 94th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address93 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address93_Low on page 17-677
The MAC Address93 Low register holds the lower 32 bits of the 94th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address94_High on page 17-678
The MAC Address94 High register holds the upper 16 bits of the 95th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address94 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address94_Low on page 17-681
The MAC Address94 Low register holds the lower 32 bits of the 95th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address95_High on page 17-682
The MAC Address95 High register holds the upper 16 bits of the 96th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address95 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address95_Low on page 17-685
The MAC Address95 Low register holds the lower 32 bits of the 96th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address96_High on page 17-686
The MAC Address96 High register holds the upper 16 bits of the 97th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address96 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address96_Low on page 17-689
The MAC Address96 Low register holds the lower 32 bits of the 97th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address97_High on page 17-690
The MAC Address97 High register holds the upper 16 bits of the 98th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address97 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address97_Low on page 17-693
The MAC Address97 Low register holds the lower 32 bits of the 98th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address98_High on page 17-694
The MAC Address98 High register holds the upper 16 bits of the 99th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address98 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address98_Low on page 17-697
The MAC Address98 Low register holds the lower 32 bits of the 99th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address99_High on page 17-698
The MAC Address99 High register holds the upper 16 bits of the 100th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address99 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address99_Low on page 17-701
The MAC Address99 Low register holds the lower 32 bits of the 100th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address100_High on page 17-702
The MAC Address100 High register holds the upper 16 bits of the 101th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address100 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address100_Low on page 17-705
The MAC Address100 Low register holds the lower 32 bits of the 101th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address101_High on page 17-706
The MAC Address101 High register holds the upper 16 bits of the 102th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address101 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address101_Low on page 17-709
The MAC Address101 Low register holds the lower 32 bits of the 102th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address102_High on page 17-710
The MAC Address102 High register holds the upper 16 bits of the 103th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address102 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address102_Low on page 17-713
The MAC Address102 Low register holds the lower 32 bits of the 103th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address103_High on page 17-714
The MAC Address103 High register holds the upper 16 bits of the 104th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address103 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address103_Low on page 17-717
The MAC Address103 Low register holds the lower 32 bits of the 104th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address104_High on page 17-718
The MAC Address104 High register holds the upper 16 bits of the 105th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address104 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address104_Low on page 17-721
The MAC Address104 Low register holds the lower 32 bits of the 105th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address105_High on page 17-722
The MAC Address105 High register holds the upper 16 bits of the 106th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address105 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address105_Low on page 17-725
The MAC Address105 Low register holds the lower 32 bits of the 106th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address106_High on page 17-726
The MAC Address106 High register holds the upper 16 bits of the 107th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address106 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address106_Low on page 17-729
The MAC Address106 Low register holds the lower 32 bits of the 107th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address107_High on page 17-730
The MAC Address107 High register holds the upper 16 bits of the 108th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address107 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address107_Low on page 17-733
The MAC Address107 Low register holds the lower 32 bits of the 108th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address108_High on page 17-734
The MAC Address108 High register holds the upper 16 bits of the 109th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address108 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address108_Low on page 17-737
The MAC Address108 Low register holds the lower 32 bits of the 109th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address109_High on page 17-738
The MAC Address109 High register holds the upper 16 bits of the 110th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address109 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address109_Low on page 17-741
The MAC Address109 Low register holds the lower 32 bits of the 110th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address110_High on page 17-742
The MAC Address110 High register holds the upper 16 bits of the 111th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address110 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address110_Low on page 17-745
The MAC Address110 Low register holds the lower 32 bits of the 111th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address111_High on page 17-746
The MAC Address111 High register holds the upper 16 bits of the 112th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address111 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address111_Low on page 17-749
The MAC Address111 Low register holds the lower 32 bits of the 112th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address112_High on page 17-750
The MAC Address112 High register holds the upper 16 bits of the 113th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address112 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address112_Low on page 17-753
The MAC Address112 Low register holds the lower 32 bits of the 113th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address113_High on page 17-754
The MAC Address113 High register holds the upper 16 bits of the 114th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address113 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address113_Low on page 17-757
The MAC Address113 Low register holds the lower 32 bits of the 114th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address114_High on page 17-758
The MAC Address114 High register holds the upper 16 bits of the 115th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address114 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address114_Low on page 17-761
The MAC Address114 Low register holds the lower 32 bits of the 115th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address115_High on page 17-762
The MAC Address115 High register holds the upper 16 bits of the 116th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address115 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address115_Low on page 17-765
The MAC Address115 Low register holds the lower 32 bits of the 116th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address116_High on page 17-766
The MAC Address116 High register holds the upper 16 bits of the 117th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address116 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address116_Low on page 17-769
The MAC Address116 Low register holds the lower 32 bits of the 117th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address117_High on page 17-770
The MAC Address117 High register holds the upper 16 bits of the 118th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address117 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address117_Low on page 17-773
The MAC Address117 Low register holds the lower 32 bits of the 118th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address118_High on page 17-774
The MAC Address118 High register holds the upper 16 bits of the 119th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address118 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address118_Low on page 17-777
The MAC Address118 Low register holds the lower 32 bits of the 119th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address119_High on page 17-778
The MAC Address119 High register holds the upper 16 bits of the 120th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address119 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address119_Low on page 17-781
The MAC Address119 Low register holds the lower 32 bits of the 120th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address120_High on page 17-782
The MAC Address120 High register holds the upper 16 bits of the 121th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address120 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address120_Low on page 17-785
The MAC Address120 Low register holds the lower 32 bits of the 121th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address121_High on page 17-786
The MAC Address121 High register holds the upper 16 bits of the 122th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address121 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address121_Low on page 17-789
The MAC Address121 Low register holds the lower 32 bits of the 122th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address122_High on page 17-790
The MAC Address122 High register holds the upper 16 bits of the 123th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address122 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address122_Low on page 17-793
The MAC Address122 Low register holds the lower 32 bits of the 123th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address123_High on page 17-794
The MAC Address123 High register holds the upper 16 bits of the 124th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address123 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address123_Low on page 17-797
The MAC Address123 Low register holds the lower 32 bits of the 124th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address124_High on page 17-798
The MAC Address124 High register holds the upper 16 bits of the 125th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address124 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address124_Low on page 17-801
The MAC Address124 Low register holds the lower 32 bits of the 125th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address125_High on page 17-802
The MAC Address125 High register holds the upper 16 bits of the 126th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address125 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address125_Low on page 17-805
The MAC Address125 Low register holds the lower 32 bits of the 126th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address126_High on page 17-806
The MAC Address126 High register holds the upper 16 bits of the 127th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address126 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address126_Low on page 17-809
The MAC Address126 Low register holds the lower 32 bits of the 127th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Address127_High on page 17-810
The MAC Address127 High register holds the upper 16 bits of the 128th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address127 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address127_Low on page 17-813
The MAC Address127 Low register holds the lower 32 bits of the 128th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

MAC_Configuration

The MAC Configuration register establishes receive and transmit operating modes.

Module Instance	Base Address	Register Address

MAC_Configuration Fields

Bit	Name	Description	Access	Reset
27	twokpe	When set, the MAC considers all frames, with up to 2,000 bytes length, as normal packets. When Bit 20 (Jumbo Enable) is not set, the MAC considers all received frames of size more than 2K bytes as Giant frames. When this bit is reset and Bit 20 (Jumbo Enable) is not set, the MAC considers all received frames of size more than 1,518 bytes (1,522 bytes for tagged) as Giant frames. When Bit 20 (Jumbo Enable) is set, setting this bit has no effect on Giant Frame status.	RW	0x0
25	cst	When set, the last 4 bytes (FCS) of all frames of Ether type (type field greater than 0x0600) are stripped and dropped before forwarding the frame to the application. This function is not valid when the IP Checksum Engine (Type 1) is enabled in the MAC receiver. **Value** **Description** 0x0 Strip Ether Frames Off 0x1 Strip Ether Frames On	RW	0x0

Bit	Name	Description	Access	Reset
24	tc	When set, this bit enables the transmission of duplex mode, link speed, and link up or down information to the PHY in the RGMII. When this bit is reset, no such information is driven to the PHY. **Value** **Description** 0x1 Enables Transmission of duplex 0x0 Disables Transmission to Phy	RW	0x0
23	wd	When this bit is set, the MAC disables the watchdog timer on the receiver. The MAC can receive frames of up to 16,384 bytes. When this bit is reset, the MAC does not allow more than 2,048 bytes (10,240 if JE is set high) of the frame being received. The MAC cuts off any bytes received after 2,048 bytes. **Value** **Description** 0x0 Enable MAC cutoff > 2048Bytes 0x1 Disable Watchdog	RW	0x0
22	jd	When this bit is set, the MAC disables the jabber timer on the transmitter. The MAC can transfer frames of up to 16,384 bytes. When this bit is reset, the MAC cuts off the transmitter if the application sends out more than 2,048 bytes of data (10,240 if JE is set high) during transmission. **Value** **Description** 0x0 MAC cuts off TX > 2048 0x1 Jabber Timer Disabled	RW	0x0
21	be	When this bit is set, the MAC allows frame bursting during transmission in the GMII half-duplex mode. **Value** **Description** 0x0 Frame Burst Enable OFF 0x1 Frame Burst Enable ON	RW	0x0

Bit	Name	Description	Access	Reset
20	je	When this bit is set, the MAC allows Jumbo frames of 9,018 bytes (9,022 bytes for VLAN tagged frames) without reporting a giant frame error in the receive frame status. **Value** **Description** 0x0 Report Jumbo Frame Error 0x1 Ignore Jumbo Frame Error	RW	0x0
19:17	ifg	These bits control the minimum IFG between frames during transmission. In the half-duplex mode, the minimum IFG can be configured only for 64 bit times (IFG = 100). Lower values are not considered. In the 1000-Mbps mode, the minimum IFG supported is 80 bit times (and above). **Value** **Description** 0x0 Inter Frame Gap 96 bit times 0x1 Inter Frame Gap 88 bit times 0x2 Inter Frame Gap 80 bit times 0x3 Inter Frame Gap 72 bit times 0x4 Inter Frame Gap 64 bit times 0x5 Inter Frame Gap 56 bit times 0x6 Inter Frame Gap 48 bit times 0x7 Inter Frame Gap 40 bit times	RW	0x0
16	dcrs	When set high, this bit makes the MAC transmitter ignore the (G)MII CRS signal during frame transmission in the half-duplex mode. This request results in no errors generated because of Loss of Carrier or No Carrier during such transmission. When this bit is low, the MAC transmitter generates such errors because of Carrier Sense and can even abort the transmissions. **Value** **Description** 0x0 MAC Tx Gen. Err. No Carrier 0x1 MAC Tx Ignores (G)MII Crs Signal	RW	0x0

Bit	Name	Description	Access	Reset
15	ps	This bit selects between GMII and MII **Value** **Description** 0x0 GMII 1000 Mbps 0x1 MII 10/100 Mbps	RW	0x0
14	fes	This bit selects the speed in the RGMII interface: * 0: 10 Mbps * 1: 100 Mbps This bit generates link speed encoding when TC (Bit 24) is set in the RGMII, SMII, or SGMII mode. **Value** **Description** 0x0 Speed = 10 Mbps 0x1 Speed = 100 Mbps	RW	0x0
13	do	When this bit is set, the MAC disables the reception of frames when the gmii_txen_o is asserted in the half-duplex mode. When this bit is reset, the MAC receives all packets that are given by the PHY while transmitting. This bit is not applicable if the MAC is operating in the full-duplex mode. **Value** **Description** 0x0 MAC Enables Reception of Frames 0x1 MAC Disables Reception of Frames	RW	0x0
12	lm	When this bit is set, the MAC operates in the loopback mode at GMII or MII. The (G)MII Receive clock input is required for the loopback to work properly, because the Transmit clock is not looped-back internally. **Value** **Description** 0x0 Disable Loop Back 0x1 Enable Loop Back	RW	0x0
11	dm	When this bit is set, the MAC operates in the full-duplex mode where it can transmit and receive simultaneously. **Value** **Description** 0x1 MAC Full Duplex Enabled 0x0 MAC Full Duplex Disabled	RW	0x0

Bit	Name	Description	Access	Reset
10	ipc	When this bit is set, the MAC calculates the 16-bit ones complement of the ones complement sum of all received Ethernet frame payloads. It also checks whether the IPv4 Header checksum (assumed to be bytes 2526 or 2930 (VLAN-tagged) of the received Ethernet frame) is correct for the received frame and gives the status in the receive status word. The MAC also appends the 16-bit checksum calculated for the IP header datagram payload (bytes after the IPv4 header) and appends it to the Ethernet frame transferred to the application (when Type 2 COE is deselected). When this bit is reset, this function is disabled. When Type 2 COE is selected, this bit, when set, enables the IPv4 header checksum checking and IPv4 or IPv6 TCP, UDP, or ICMP payload checksum checking. When this bit is reset, the COE function in the receiver is disabled and the corresponding PCE and IP HCE status bits are always cleared. **Value** **Description** 0x1 Checksum Enabled 0x0 Checksum Disabled	RW	0x0
9	dr	When this bit is set, the MAC attempts only one transmission. When a collision occurs on the GMII or MII interface, the MAC ignores the current frame transmission and reports a Frame Abort with excessive collision error in the transmit frame status. When this bit is reset, the MAC attempts retries based on the settings of the BL field (Bits [6:5]). This bit is applicable only in the half-duplex mode. **Value** **Description** 0x1 MAC attempts one transmission 0x0 MAC attempts retries per bl Field	RW	0x0
8	lud	This bit indicates whether the link is up or down during the transmission of configuration in the RGMII, SGMII, or SMII interface **Value** **Description** 0x0 Link Down 0x1 Link Up	RW	0x0

Bit	Name	Description	Access	Reset
7	acs	When this bit is set, the MAC strips the Pad or FCS field on the incoming frames only if the value of the length field is less than 1,536 bytes. All received frames with length field greater than or equal to 1,536 bytes are passed to the application without stripping the Pad or FCS field. When this bit is reset, the MAC passes all incoming frames, without modifying them, to the Host. **Value** — **Description** 0x0 — Disable Automatic Pad CRC Stripping 0x1 — Enable Automatic Pad CRC Stripping	RW	0x0
6:5	bl	The Back-Off limit determines the random integer number (r) of slot time delays (4,096 bit times for 1000 Mbps and 512 bit times for 10/100 Mbps) for which the MAC waits before rescheduling a transmission attempt during retries after a collision. This bit is applicable only in the half-duplex mode. * 00: k = min (n, 10) * 01: k = min (n, 8) * 10: k = min (n, 4) * 11: k = min (n, 1) where n = retransmission attempt. The random integer r takes the value in the range 0 <= r < kth power of 2 **Value** — **Description** 0x0 — k = min (n, 10) 0x1 — k = min (n, 8) 0x2 — k = min (n, 4) 0x3 — k = min (n, 1)	RW	0x0

Bit	Name	Description	Access	Reset
4	dc	When this bit is set, the deferral check function is enabled in the MAC. The MAC issues a Frame Abort status, along with the excessive deferral error bit set in the transmit frame status, when the transmit state machine is deferred for more than 24,288 bit times in the 10 or 100 Mbps mode. If the MAC is configured for 1000 Mbps operation, or if the Jumbo frame mode is enabled in the 10 or 100 Mbps mode, the threshold for deferral is 155,680 bits times. Deferral begins when the transmitter is ready to transmit, but is prevented because of an active carrier sense signal (CRS) on GMII or MII. Defer time is not cumulative. When the transmitter defers for 10,000 bit times, it transmits, collides, backs off, and then defers again after completion of back-off. The deferral timer resets to 0 and restarts. When this bit is reset, the deferral check function is disabled and the MAC defers until the CRS signal goes inactive. This bit is applicable only in the half-duplex mode. **Value** **Description** 0x1 Deferral Check Enabled 0x0 Deferral Check Disabled	RW	0x0
3	te	When this bit is set, the transmit state machine of the MAC is enabled for transmission on the GMII or MII. When this bit is reset, the MAC transmit state machine is disabled after the completion of the transmission of the current frame, and does not transmit any further frames. **Value** **Description** 0x0 MAC transmit state machine disabled 0x1 MAC transmit state machine disabled	RW	0x0
2	re	When this bit is set, the receiver state machine of the MAC is enabled for receiving frames from the GMII or MII. When this bit is reset, the MAC receive state machine is disabled after the completion of the reception of the current frame, and does not receive any further frames from the GMII or MII. **Value** **Description** 0x0 MAC receive state machine disabled 0x1 MAC receive state machine enabled	RW	0x0

Bit	Name	Description	Access	Reset
1:0	prelen	These bits control the number of preamble bytes that are added to the beginning of every Transmit frame. The preamble reduction occurs only when the MAC is operating Value: 0x0 — Description: Preamble 7 Bytes Value: 0x1 — Description: Preamble 5 Bytes Value: 0x2 — Description: Preamble 3 Bytes	RW	0x0

MAC_Frame_Filter

The MAC Frame Filter register contains the filter controls for receiving frames. Some of the controls from this register go to the address check block of the MAC, which performs the first level of address filtering. The second level of filtering is performed on the incoming frame, based on other controls such as Pass Bad Frames and Pass Control Frames.

Module Instance	Base Address	Register Address

MAC_Frame_Filter Fields

Bit	Name	Description	Access	Reset
31	ra	When this bit is set, the MAC Receiver block passes all received frames, irrespective of whether they pass the address filter or not, to the Application. The result of the SA or DA filtering is updated (pass or fail) in the corresponding bits in the Receive Status Word. When this bit is reset, the Receiver block passes only those frames to the Application that pass the SA or DA address filter. **Value** **Description** 0x0 Receive All off 0x1 Receive All On	RW	0x0
21	dntu	When set, this bit enables the MAC to drop the non-TCP or UDP over IP frames. The MAC forward only those frames that are processed by the Layer 4 filter. When reset, this bit enables the MAC to forward all non-TCP or UDP over IP frames. **Value** **Description** 0x0 Forward all non-TCP or UDP over IP frames 0x1 Drop non-TCP or UDP over IP frames	RW	0x0
20	ipfe	When set, this bit enables the MAC to drop frames that do not match the enabled Layer 3 and Layer 4 filters. If Layer 3 or Layer 4 filters are not enabled for matching, this bit does not have any effect. When reset, the MAC forwards all frames irrespective of the match status of the Layer 3 and Layer 4 filters. **Value** **Description** 0x0 Forward all frames irrespective of the match status of Layer 3 and Layer 4 filters 0x1 Drop frames that do not match the enabled Layer 3 and Layer 4 filters	RW	0x0

Bit	Name	Description	Access	Reset
16	vtfe	When set, this bit enables the MAC to drop VLAN tagged frames that do not match the VLAN Tag comparison. When reset, the MAC forwards all frames irrespective of the match status of the VLAN Tag. **Value** **Description** 0x0 Forward all frames irrespective of the match status of the VLAN tag 0x1 Drop VLAN tagged frames that do not match the VLAN Tag comparison	RW	0x0
10	hpf	When this bit is set, it configures the address filter to pass a frame if it matches either the perfect filtering or the hash filtering as set by the HMC or HUC bits. When this bit is low and the HUC or HMC bit is set, the frame is passed only if it matches the Hash filter. **Value** **Description** 0x0 Hash or Perfect Filter off 0x1 Hash or Perfect Filter on	RW	0x0
9	saf	When this bit is set, the MAC compares the SA field of the received frames with the values programmed in the enabled SA registers. If the comparison matches, then the SA Match bit of RxStatus Word is set high. When this bit is set high and the SA filter fails, the MAC drops the frame. When this bit is reset, the MAC forwards the received frame to the application and with the updated SA Match bit of the RxStatus depending on the SA address comparison. **Value** **Description** 0x0 SA Filter Off 0x1 SA Filter On	RW	0x0

Bit	Name	Description	Access	Reset
8	saif	When this bit is set, the Address Check block operates in inverse filtering mode for the SA address comparison. The frames whose SA matches the SA registers are marked as failing the SA Address filter. When this bit is reset, frames whose SA does not match the SA registers are marked as failing the SA Address filter. **Value** — **Description** 0x0 — SA Nomatch Fail 0x1 — SA Match Fail	RW	0x0

Bit	Name	Description	Access	Reset
7:6	pcf	These bits control the forwarding of all control frames (including unicast and multicast PAUSE frames). * 00: MAC filters all control frames from reaching the application. * 01: MAC forwards all control frames except PAUSE control frames to application even if they fail the Address filter. * 10: MAC forwards all control frames to application even if they fail the Address Filter. * 11: MAC forwards control frames that pass the Address Filter. The following conditions should be true for the PAUSE control frames processing: * Condition 1: The MAC is in the full-duplex mode and flow control is enabled by setting Bit 2 (RFE) of Register 6 (Flow Control Register) to 1. * Condition 2: The destination address (DA) of the received frame matches the special multicast address or the MAC Address 0 when Bit 3 (UP) of the Register 6 (Flow Control Register) is set. * Condition 3: The Type field of the received frame is 0x8808 and the OPCODE field is 0x0001. This field should be set to 01 only when the Condition 1 is true, that is, the MAC is programmed to operate in the full-duplex mode and the RFE bit is enabled. Otherwise, the PAUSE frame filtering may be inconsistent. When Condition 1 is false, the PAUSE frames are considered as generic control frames. Therefore, to pass all control frames (including PAUSE control frames) when the full-duplex mode and flow control is not enabled, you should set the PCF field to 10 or 11 (as required by the application). **Value** **Description** 0x0 MAC filters all control frames 0x1 MAC forwards all control frames except PAUSE 0x2 MAC forwards all control frames fail addrflt 0x3 MAC forwards control frames that pass addrflt	RW	0x0
5	dbf	When this bit is set, the AFM block filters all incoming broadcast frames. In addition, it overrides all other filter settings. When this bit is reset, the AFM block passes all received broadcast frames. **Value** **Description** 0x0 Pass All Broadcast Frames 0x1 Filter All Broadcast Frames	RW	0x0

Bit	Name	Description	Access	Reset
4	pm	When set, this bit indicates that all received frames with a multicast destination address (first bit in the destination address field is '1') are passed. When reset, filtering of multicast frame depends on HMC bit. **Value** **Description** 0x0 Allows Filter of MC Frames 0x1 All Rcvd MC Frames Pass	RW	0x0
3	daif	When this bit is set, the Address Check block operates in inverse filtering mode for the DA address comparison for both unicast and multicast frames. When reset, normal filtering of frames is performed. **Value** **Description** 0x0 Normal Inverse Filter 0x1 Address Check Block Inverse Filter	RW	0x0
2	hmc	When set, MAC performs destination address filtering of received multicast frames according to the hash table. When reset, the MAC performs a perfect destination address filtering for multicast frames, that is, it compares the DA field with the values programmed in DA registers. **Value** **Description** 0x0 MAC Filters with Compare 0x1 MAC Filters with Hash Table	RW	0x0
1	huc	When set, MAC performs destination address filtering of unicast frames according to the hash table. When reset, the MAC performs a perfect destination address filtering for unicast frames, that is, it compares the DA field with the values programmed in DA registers. **Value** **Description** 0x0 MAC Filters with Compare 0x1 MAC Filters with Hash Table	RW	0x0

Bit	Name	Description	Access	Reset
0	pr	When this bit is set, the Address Filter block passes all incoming frames regardless of its destination or source address. The SA or DA Filter Fails status bits of the Receive Status Word are always cleared when PR is set. **Value** **Description** 0x0 Clear SA DA Status Bits 0x1 All Incoming Frames Passed	RW	0x0

GMII_Address

The GMII Address register controls the management cycles to the external PHY through the management interface.

Module Instance	Base Address	Register Address

GMII_Address Fields

Bit	Name	Description	Access	Reset
15:11	pa	This field indicates which of the 32 possible PHY devices are being accessed. For RevMII, this field gives the PHY Address of the RevMII block.	RW	0x0
10:6	gr	These bits select the desired GMII register in the selected PHY device. For RevMII, these bits select the desired CSR register in the RevMII Registers set.	RW	0x0

Bit	Name	Description	Access	Reset
5:2	cr	The CSR Clock Range selection determines the frequency of the MDC clock according to the l3_sp_clk frequency used in your design. The suggested range of l3_sp_clk frequency applicable for each value (when Bit[5] = 0) ensures that the MDC clock is approximately between the frequency range 1.0 MHz - 2.5 MHz. When Bit 5 is set, you can achieve MDC clock of frequency higher than the IEEE 802.3 specified frequency limit of 2.5 MHz and program a clock divider of lower value. For example, when l3_sp_clk is of 100 MHz frequency and you program these bits as 1010, then the resultant MDC clock is of 12.5 MHz which is outside the limit of IEEE 802.3 specified range. Only use the values larger than 7 if the interfacing chips support faster MDC clocks. **Value** — **Description** 0x0 — l3_sp_clk 60-100Mhz and MDC clock = l3_sp_clk/42 0x1 — l3_sp_clk 100-150Mhz and MDC clock = l3_sp_clk/62 0x2 — l3_sp_clk 25-35Mhz and MDC clock = l3_sp_clk/16 0x3 — l3_sp_clk 35-60Mhz and MDC clock = l3_sp_clk/26 0x4 — l3_sp_clk 150-250Mhz and MDC clock = l3_sp_clk/102 0x5 — l3_sp_clk 250-300Mhz and MDC clock = l3_sp_clk/124 0x8 — l3_sp_clk/4 0x9 — l3_sp_clk/6 0xa — l3_sp_clk/8 0xb — l3_sp_clk/10 0xc — l3_sp_clk/12 0xd — l3_sp_clk/14 0xe — l3_sp_clk/16 0xf — l3_sp_clk/18	RW	0x0

Bit	Name	Description	Access	Reset
1	gw	When set, this bit indicates to the PHY or RevMII that this is a Write operation using the GMII Data register. If this bit is not set, it indicates that this is a Read operation, that is, placing the data in the GMII Data register. **Value** **Description** 0x0 GMII Read Operation 0x1 GMII Write Operation	RW	0x0
0	gb	This bit should read logic 0 before writing to Register 4 and Register 5. During a PHY or RevMII register access, the software sets this bit to 1'b1 to indicate that a Read or Write access is in progress. The Register 5 is invalid until this bit is cleared by the MAC. Therefore, Register 5 (GMII Data) should be kept valid until the MAC clears this bit during a PHY Write operation. Similarly for a read operation, the contents of Register 5 are not valid until this bit is cleared. The subsequent read or write operation should happen only after the previous operation is complete. Because there is no acknowledgment from the PHY to MAC after a read or write operation is completed, there is no change in the functionality of this bit even when the PHY is not present. **Value** **Description** 0x0 Not Busy 0x1 Busy	RW	0x0

GMII_Data

The GMII Data register stores Write data to be written to the PHY register located at the address specified in Register 4 (GMII Address Register). This register also stores the Read data from the PHY register located at the address specified by Register 4.

Module Instance	Base Address	Register Address

15:0	gd	This field contains the 16-bit data value read from the PHY or RevMII after a Management Read operation or the 16-bit data value to be written to the PHY or RevMII before a Management Write operation.	RW	0x0

Flow_Control

The Flow Control register controls the generation and reception of the Control (Pause Command) frames by the MAC's Flow control block. A Write to a register with the Busy bit set to '1' triggers the Flow Control block to generate a Pause Control frame. The fields of the control frame are selected as specified in the 802.3x specification, and the Pause Time value from this register is used in the Pause Time field of the control frame. The Busy bit remains set until the control frame is transferred onto the cable. The Host must make sure that the Busy bit is cleared before writing to the register.

Flow_Control Fields

Bit	Name	Description	Access	Reset
31:16	pt	This field holds the value to be used in the Pause Time field in the transmit control frame. Because the Pause Time bits are double-synchronized to the (G) MII clock domain, then consecutive writes to this register should be performed only after at least four clock cycles in the destination clock domain.	RW	0x0
7	dzpq	When this bit is set, it disables the automatic generation of the Zero-Quanta Pause Control frames on the de-assertion of the flow-control signal from the FIFO layer (MTL or external sideband flow control signal sbd_flowctrl_i/mti_flowctrl_i). When this bit is reset, normal operation with automatic Zero-Quanta Pause Control frame generation is enabled. **Value** — **Description** 0x1 — Disable Auto Gen. of Zero-Quanta Pause 0x0 — Enable Auto Gen. of Zero-Quanta Pause	RW	0x0
5:4	plt	This field configures the threshold of the PAUSE timer at which the input flow control signal mti_flowctrl_i (or sbd_flowctrl_i) is checked for automatic retransmission of PAUSE Frame. The threshold values should be always less than the Pause Time configured in Bits[31:16]. For example, if PT = 100H (256 slot-times), and PLT = 01, then a second PAUSE frame is automatically transmitted if the mti_flowctrl_i signal is asserted at 228 (256 - 28) slot times after the first PAUSE frame is transmitted. The slot time is defined as the time taken to transmit 512 bits (64 bytes) on the GMII or MII interface. **Value** — **Description** 0x0 — Pause time - 4 slot times 0x1 — Pause time - 28 slot times 0x2 — Pause time - 144 slot times 0x3 — Pause time - 256 slot times	RW	0x0

Bit	Name	Description	Access	Reset
3	up	When this bit is set, then in addition to the detecting Pause frames with the unique multicast address, the MAC detects the Pause frames with the station's unicast address specified in the MAC Address0 High Register and MAC Address0 Low Register. When this bit is reset, the MAC detects only a Pause frame with the unique multicast address specified in the 802.3x standard. **Value** **Description** 0x0 MAC Detects Pause MCA 0x1 MAC Detects Pause MCA and UCA	RW	0x0
2	rfe	When this bit is set, the MAC decodes the received Pause frame and disables its transmitter for a specified (Pause) time. When this bit is reset, the decode function of the Pause frame is disabled. **Value** **Description** 0x0 Decode Func. of Pause Frame Disabled 0x1 MAC decodes the received Pause	RW	0x0
1	tfe	In the full-duplex mode, when this bit is set, the MAC enables the flow control operation to transmit Pause frames. When this bit is reset, the flow control operation in the MAC is disabled, and the MAC does not transmit any Pause frames. In half-duplex mode, when this bit is set, the MAC enables the back-pressure operation. When this bit is reset, the back-pressure feature is disabled. **Value** **Description** 0x0 Transmit Flow Control Disable 0x1 Transmit Flow Control Enable	RW	0x0

Bit	Name	Description	Access	Reset
0	fca_bpa	This bit initiates a Pause Control frame in the full-duplex mode and activates the backpressure function in the half-duplex mode if the TFE bit is set. In the full-duplex mode, this bit should be read as 1'b0 before writing to the Flow Control register. To initiate a Pause control frame, the Application must set this bit to 1'b1. During a transfer of the Control Frame, this bit continues to be set to signify that a frame transmission is in progress. After the completion of Pause control frame transmission, the MAC resets this bit to 1'b0. The Flow Control register should not be written to until this bit is cleared. In the half-duplex mode, when this bit is set (and TFE is set) , then backpressure is asserted by the MAC. During backpressure, when the MAC receives a new frame, the transmitter starts sending a JAM pattern resulting in a collision. This control register bit is logically ORed with the mti_flowctrl_i input signal for the backpressure function. When the MAC is configured for the full-duplex mode, the BPA is automatically disabled. **Value** **Description** 0x0 Pause Ctrl Frame and BPA off 0x1 Init Pause Ctrl Frame and BPA	RW	0x0

VLAN_Tag

The VLAN Tag register contains the IEEE 802.1Q VLAN Tag to identify the VLAN frames. The MAC compares the 13th and 14th bytes of the receiving frame (Length/Type) with 16'h8100, and the following two bytes are compared with the VLAN tag. If a match occurs, the MAC sets the received VLAN bit in the receive frame status. The legal length of the frame is increased from 1,518 bytes to 1,522 bytes. Because the VLAN Tag register is double-synchronized to the (G)MII clock domain, then consecutive writes to these register should be performed only after at least four clock cycles in the destination clock domain.

VLAN_Tag Fields

Bit	Name	Description	Access	Reset
19	vthm	When set, the most significant four bits of the VLAN tag's CRC are used to index the content of Register 354 (VLAN Hash Table Register). A value of 1 in the VLAN Hash Table register, corresponding to the index, indicates that the frame matched the VLAN hash table. When Bit 16 (ETV) is set, the CRC of the 12-bit VLAN Identifier (VID) is used for comparison whereas when ETV is reset, the CRC of the 16-bit VLAN tag is used for comparison. When reset, the VLAN Hash Match operation is not performed.	RW	0x0
18	esvl	When this bit is set, the MAC transmitter and receiver also consider the S-VLAN (Type = 0x88A8) frames as valid VLAN tagged frames.	RW	0x0
17	vtim	When set, this bit enables the VLAN Tag inverse matching. The frames that do not have matching VLAN Tag are marked as matched. When reset, this bit enables the VLAN Tag perfect matching. The frames with matched VLAN Tag are marked as matched.	RW	0x0
16	etv	When this bit is set, a 12-bit VLAN identifier is used for comparing and filtering instead of the complete 16-bit VLAN tag. Bits [11:0] of VLAN tag are compared with the corresponding field in the received VLAN-tagged frame. Similarly, when enabled, only 12 bits of the VLAN tag in the received frame are used for hash-based VLAN filtering. When this bit is reset, all 16 bits of the 15th and 16th bytes of the received VLAN frame are used for comparison and VLAN hash filtering. **Value** — **Description** 0x0 — Disable 12-Bit VLAN Tag Compare 0x1 — Enable 12-Bit VLAN Tag Compare	RW	0x0

Bit	Name	Description	Access	Reset
15:0	vl	This field contains the 802.1Q VLAN tag to identify the VLAN frames and is compared to the 15th and 16th bytes of the frames being received for VLAN frames. The following list describes the bits of this field: * Bits [15:13]: User Priority * Bit 12: Canonical Format Indicator (CFI) or Drop Eligible Indicator (DEI) * Bits[11:0]: VLAN tag's VLAN Identifier (VID) field When the ETV bit is set, only the VID (Bits[11:0]) is used for comparison. If VL (VL[11:0] if ETV is set) is all zeros, the MAC does not check the fifteenth and 16th bytes for VLAN tag comparison, and declares all frames with a Type field value of 0x8100 or 0x88a8 as VLAN frames.	RW	0x0

Version

The Version registers identifies the version of the EMAC. This register contains two bytes: one specified by Synopsys to identify the core release number, and the other specified by Altera.

Module Instance	Base Address	Register Address

LPI_Control_Status Fields

Bit	Name	Description	Access	Reset
19	lpitxa	This bit controls the behavior of the MAC when it is entering or coming out of the LPI mode on the transmit side. This bit is not functional in the GMAC-CORE configuration in which the Tx clock gating is done during the LPI mode. If the LPITXA and LPIEN bits are set to 1, the MAC enters the LPI mode only after all outstanding frames (in the core) and pending frames (in the application interface) have been transmitted. The MAC comes out of the LPI mode when the application sends any frame for transmission or the application issues a TX FIFO Flush command. In addition, the MAC automatically clears the LPIEN bit when it exits the LPI state. If TX FIFO Flush is set, in Bit 20 of Register 6 (Operation Mode Register), when the MAC is in the LPI mode, the MAC exits the LPI mode. When this bit is 0, the LPIEN bit directly controls behavior of the MAC when it is entering or coming out of the LPI mode. **Value** — **Description** 0x0 — LPI TX Automate Disabled 0x1 — LPI TX Automate Enabled	RW	0x0
18	plsen	This bit enables the link status received on the RGMII receive paths to be used for activating the LPI LS TIMER. When set, the MAC uses the link-status bits of Register 54 (SGMII/RGMII/SMII Status Register) and Bit 17 (PLS) for the LPI LS Timer trigger. When cleared, the MAC ignores the link-status bits of Register 54 and takes only the PLS bit. **Value** — **Description** 0x0 — MAC Ignores Link Status Bits 0x1 — MAC Uses Link Status Bits	RW	0x0
17	pls	This bit indicates the link status of the PHY. The MAC Transmitter asserts the LPI pattern only when the link status is up (okay) at least for the time indicated by the LPI LS TIMER. When set, the link is considered to be okay (up) and when reset, the link is considered to be down. **Value** — **Description** 0x0 — Link Down 0x1 — Link Up (okay)	RW	0x0

Bit	Name	Description	Access	Reset
16	lpien	When set, this bit instructs the MAC Transmitter to enter the LPI state. When reset, this bit instructs the MAC to exit the LPI state and resume normal transmission. This bit is cleared when the LPITXA bit is set and the MAC exits the LPI state because of the arrival of a new packet for transmission. **Value** **Description** 0x0 MAC Transmitter exit LPI State 0x1 MAC Transmitter enters LPI State	RW	0x0
9	rlpist	When set, this bit indicates that the MAC is receiving the LPI pattern on the GMII or MII interface. **Value** **Description** 0x0 MAC is not receiving LPI Pattern 0x1 MAC receiving LPI Pattern	RO	0x0
8	tlpist	When set, this bit indicates that the MAC is transmitting the LPI pattern on the GMII or MII interface. **Value** **Description** 0x0 MAC Transmitting LPI Pattern 0x1 MAC Transmitting LPI Pattern	RO	0x0
3	rlpiex	When set, this bit indicates that the MAC Receiver has stopped receiving the LPI pattern on the GMII or MII interface, exited the LPI state, and resumed the normal reception. This bit is cleared by a read into this register. Note: This bit may not get set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than 3 clock cycles of l3_sp_clk. **Value** **Description** 0x0 MAC RX receiving LPI Patterns 0x1 MAC RX Stopped receiving LPI Patterns	RO	0x0

Bit	Name	Description	Access	Reset
2	rlpien	When set, this bit indicates that the MAC Receiver has received an LPI pattern and entered the LPI state. This bit is cleared by a read into this register. Note: This bit may not get set if the MAC stops receiving the LPI pattern for a very short duration, such as, less than 3 clock cycles of l3_sp_clk. **Value** **Description** 0x0 MAC Receiver Not In LPI State 0x1 MAC Receiver In LPI State	RO	0x0
1	tlpiex	When set, this bit indicates that the MAC transmitter has exited the LPI state after the user has cleared the LPIEN bit and the LPI TW Timer has expired. This bit is cleared by a read into this register. **Value** **Description** 0x0 MAC Transmitter Non LPI State 0x1 MAC Transmitter Exited LPI State	RO	0x0
0	tlpien	When set, this bit indicates that the MAC Transmitter has entered the LPI state because of the setting of the LPIEN bit. This bit is cleared by a read into this register. **Value** **Description** 0x0 MAC Transmitter Not in LPI State 0x1 MAC Transmitter Entered LPI State	RO	0x0

LPI_Timers_Control

The LPI Timers Control register controls the timeout values in the LPI states. It specifies the time for which the MAC transmits the LPI pattern and also the time for which the MAC waits before resuming the normal transmission.

Module Instance	Base Address	Register Address

LPI_Timers_Control Fields

Bit	Name	Description	Access	Reset
25:16	lst	This field specifies the minimum time (in milliseconds) for which the link status from the PHY should be up (OKAY) before the LPI pattern can be transmitted to the PHY. The MAC does not transmit the LPI pattern even when the LPIEN bit is set unless the LPI LS Timer reaches the programmed terminal count. The default value of the LPI LS Timer is 1000 (1 sec) as defined in the IEEE standard.	RW	0x3E8
15:0	twt	This field specifies the minimum time (in microseconds) for which the MAC waits after it stops transmitting the LPI pattern to the PHY and before it resumes the normal transmission. The TLPIEX status bit is set after the expiry of this timer.	RW	0x0

Interrupt_Status

The Interrupt Status register identifies the events in the MAC that can generate interrupt. All interrupt events are generated only when the corresponding optional feature is enabled.

Module Instance	Base Address	Register Address

MAC_Address0_High

The MAC Address0 High register holds the upper 16 bits of the first 6-byte MAC address of the station. The first DA byte that is received on the (G)MII interface corresponds to the LS byte (Bits [7:0]) of the MAC Address Low register. For example, if 0x112233445566 is received (0x11 in lane 0 of the first column) on the (G)MII as the destination address, then the MacAddress0 Register [47:0] is compared with 0x665544332211. Because the MAC address registers are double-synchronized to the (G)MII clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address0 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain.

Module Instance	Base Address	Register Address

MAC_Address0_Low Fields

Bit	Name	Description	Access	Reset
31:0	addrlo	This field contains the lower 32 bits of the first 6-byte MAC address. This is used by the MAC for filtering the received frames and inserting the MAC address in the Transmit Flow Control (PAUSE) Frames.	RW	0xFFFFFFFF

MAC_Address1_High

The MAC Address1 High register holds the upper 16 bits of the 2nd 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address1 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

The MAC Address5 High register holds the upper 16 bits of the 6th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address5 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address10_High

The MAC Address10 High register holds the upper 16 bits of the 11th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address10 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

MAC_Address14_High

The MAC Address14 High register holds the upper 16 bits of the 15th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address14 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MMC_Control Fields

Bit	Name	Description	Access	Reset
8	ucdbc	When set, this bit enables MAC to update all the related MMC Counters for Broadcast frames dropped due to setting of DBF bit (Disable Broadcast Frames) of MAC Filter Register at offset 0x0004. When reset, MMC Counters are not updated for dropped Broadcast frames.	RW	0x0

Bit	Name	Description	Access	Reset
5	cntprstlvl	When low and bit 4 is set, all MMC counters get preset to almost-half value. All octet counters get preset to 0x7FFF_F800 (half - 2KBytes) and all frame-counters gets preset to 0x7FFF_FFF0 (half - 16). When this bit is high and bit 4 is set, all MMC counters get preset to almost-full value. All octet counters get preset to 0xFFFF_F800 (full - 2KBytes) and all frame-counters gets preset to 0xFFFF_FFF0 (full - 16). For 16-bit counters, the almost-half preset values are 0x7800 and 0x7FF0 for the respective octet and frame counters. Similarly, the almost-full preset values for the 16-bit counters are 0xF800 and 0xFFF0. **Value** **Description** 0x0 Preset All Counters to almost-half 0x1 Present All Counters almost-full	RW	0x0
4	cntprst	When this bit is set, all counters are initialized or preset to almost full or almost half according to bit 5. This bit is cleared automatically after 1 clock cycle. This bit, along with bit 5, is useful for debugging and testing the assertion of interrupts because of MMC counter becoming half-full or full. **Value** **Description** 0x0 Counters not preset 0x1 Counters preset to full or almost full	RW	0x0
3	cntfreez	When this bit is set, it freezes all MMC counters to their current value. Until this bit is reset to 0, no MMC counter is updated because of any transmitted or received frame. If any MMC counter is read with the Reset on Read bit set, then that counter is also cleared in this mode. **Value** **Description** 0x0 Update MMC Counters 0x1 Freeze MMC counters to current value	RW	0x0

Bit	Name	Description	Access	Reset
2	rstonrd	When this bit is set, the MMC counters are reset to zero after Read (self-clearing after reset). The counters are cleared when the least significant byte lane (bits[7:0]) is read. **Value** **Description** 0x0 No reset after read 0x1 Reset after read	RW	0x0
1	cntstopro	When this bit is set, after reaching maximum value, the counter does not roll over to zero. **Value** **Description** 0x0 Counter Roll Over 0x1 Counter does not Roll Over	RW	0x0
0	cntrst	When this bit is set, all counters are reset. This bit is cleared automatically after one clock cycle. **Value** **Description** 0x0 Auto cleared after 1 clock cycle 0x1 All Counters Reset	RW	0x0

MMC_Receive_Interrupt

The MMC Receive Interrupt register maintains the interrupts that are generated when the following happens: * Receive statistic counters reach half of their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter). * Receive statistic counters cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When the Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

Module Instance	Base Address	Register Address

21	rxfovfis	This bit is set when the rxfifooverflow counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 rxfifooverflow < half max 0x1 rxfifooverflow >= half max	RO	0x0
20	rxpausfis	This bit is set when the rxpauseframe counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 rxpauseframe < half max 0x1 rxpauseframe >= half max	RO	0x0
19	rxorangefis	This bit is set when the rxoutofrangetype counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 rxoutofrangetype < half max 0x1 rxoutofrangetype >= half max	RO	0x0
18	rxlenerfis	This bit is set when the rxlengtherror counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 rxlengtherror < half max 0x1 rxlengtherror >= half max	RO	0x0
17	rxucgfis	This bit is set when the rxunicastframes_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 rx1024tomaxoctets_gb < half max 0x1 rx1024tomaxoctets_gb >= half max	RO	0x0

Bit	Name	Description	Access	Reset
16	rx1024tmaxoctgbfis	This bit is set when the rx1024tomaxoctets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 rx1024tomaxoctets_gb < half max 0x1 rx1024tomaxoctets_gb >= half max	RO	0x0
15	rx512t1023octgbfis	This bit is set when the rx512to1023octets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 rx512to1023octets_gb < half max 0x1 rx512to1023octets_gb >= half max	RO	0x0
14	rx256t511octgbfis	This bit is set when the rx256to511octets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 rx256to511octets_gb < half max 0x1 rx256to511octets_gb >= half max	RO	0x0
13	rx128t255octgbfis	This bit is set when the rx128to255octets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 rx128to255octets_gb < half max 0x1 rx128to255octets_gb >= half max	RO	0x0
12	rx65t127octgbfis	This is set when the rx65to127octets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 rx65to127octets_gb < half max 0x1 rx65to127octets_gb >= half max	RO	0x0

Bit	Name	Description	Access	Reset
11	rx64octgbfis	This bit is set when the rx64octets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 rx64octets_gb < half max 0x1 rx64octets_gb >= half max	RO	0x0
10	rxosizegfis	This bit is set when the rxoversize_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 rxoversize_g < half max 0x1 rxoversize_g >= half max	RO	0x0
9	rxusizegfis	This bit is set when the rxundersize_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 rxundersize_g < half max 0x1 rxundersize_g >= half max	RO	0x0
8	rxjaberfis	This bit is set when the rxjabbererror counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 rxjabbererror < half max 0x1 rxjabbererror >= half max	RO	0x0
7	rxruntfis	This bit is set when the rxrunterror counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 rxrunterror < half max 0x1 rxrunterror >= half max	RO	0x0

Bit	Name	Description	Access	Reset
6	rxalgnerfis	This bit is set when the rxalignmenterror counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 rxalignmenterror < half max 0x1 rxalignmenterror >= half max	RO	0x0
5	rxcrcerfis	This bit is set when the rxcrcerror counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 rxcrcerror < half max 0x1 rxcrcerror >= half max	RO	0x0
4	rxmcgfis	This bit is set when the rxmulticastframes_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 rxbroadcastframes_g < half max 0x1 rxbroadcastframes_g >= half max	RO	0x0
3	rxbcgfis	This bit is set when the rxbroadcastframes_g counter reaches half of the maximum value or the maximum value.	RO	0x0
2	rxgoctis	This bit is set when the rxoctetcount_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 Rxoctetcount_g < half max 0x1 Rxoctetcount_g >= half max	RO	0x0
1	rxgboctis	This bit is set when the rxoctetcount_bg counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 Rxoctetcount_bg < half max 0x1 Rxoctetcount_bg >= half max	RO	0x0

Bit	Name	Description	Access	Reset
0	rxgbfrmis	This bit is set when the rxframecount_bg counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 Preset All Counters to almost-half 0x1 Present All Counters almost-full	RO	0x0

MMC_Transmit_Interrupt

The MMC Transmit Interrupt register maintains the interrupts generated when transmit statistic counters reach half of their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter), and the maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Transmit Interrupt register is a 32-bit wide register. An interrupt bit is cleared when the respective MMC counter that caused the interrupt is read. The least significant byte lane (Bits[7:0]) of the respective counter must be read in order to clear the interrupt bit.

13	txuflowerfim	Setting this bit masks the interrupt when the txunderflowerror counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0

Bit	Name	Description	Access	Reset
12	txbcgbfim	Setting this bit masks the interrupt when the txbroadcastframes_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
11	txmcgbfim	Setting this bit masks the interrupt when the txmulticastframes_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
10	txucgbfim	Setting this bit masks the interrupt when the txunicastframes_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
9	tx1024tmaxoctgbfim	Setting this bit masks the interrupt when the tx1024tomaxoctets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
8	tx512t1023octgbfim	Setting this bit masks the interrupt when the tx512to1023octets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0

Bit	Name	Description	Access	Reset
7	tx256t511octgbfim	Setting this bit masks the interrupt when the tx256to511octets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
6	tx128t255octgbfim	Setting this bit masks the interrupt when the tx128to255octets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
5	tx65t127octgbfim	Setting this bit masks the interrupt when the tx65to127octets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
4	tx64octgbfim	Setting this bit masks the interrupt when the tx64octets_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
3	txmcgfim	Setting this bit masks the interrupt when the txmulticastframes_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0

Bit	Name	Description	Access	Reset
2	txbcgfim	Setting this bit masks the interrupt when the txbroadcastframes_g counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
1	txgbfrmim	Setting this bit masks the interrupt when the txframecount_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
0	txgboctim	Setting this bit masks the interrupt when the txoctetcount_gb counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0

txoctetcount_gb

Number of bytes transmitted, exclusive of preamble and retried bytes, in good and bad frames

Module Instance	Base Address	Register Address

18	rxipv4nopayoim	Setting this bit masks the interrupt when the rxipv4_nopay_octets counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
17	rxipv4heroim	Setting this bit masks the interrupt when the rxipv4_hdrerr_octets counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
16	rxipv4goim	Setting this bit masks the interrupt when the rxipv4_gd_octets counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
13	rxicmperfim	Setting this bit masks the interrupt when the rxicmp_err_frms counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
12	rxicmpgfim	Setting this bit masks the interrupt when the rxicmp_gd_frms counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0

Bit	Name	Description	Access	Reset
11	rxtcperfim	Setting this bit masks the interrupt when the rxtcp_err_frms counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
10	rxtcpgfim	Setting this bit masks the interrupt when the rxtcp_gd_frms counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
9	rxudperfim	Setting this bit masks the interrupt when the rxudp_err_frms counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
8	rxudpgfim	Setting this bit masks the interrupt when the rxudp_gd_frms counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
7	rxipv6nopayfim	Setting this bit masks the interrupt when the rxipv6_nopay_frms counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0

Bit	Name	Description	Access	Reset
6	rxipv6herfim	Setting this bit masks the interrupt when the rxipv6_hdrerr_frms counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
5	rxipv6gfim	Setting this bit masks the interrupt when the rxipv6_gd_frms counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
4	rxipv4udsblfim	Setting this bit masks the interrupt when the rxipv4_udsbl_frms counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
3	rxipv4fragfim	Setting this bit masks the interrupt when the rxipv4_frag_frms counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
2	rxipv4nopayfim	Setting this bit masks the interrupt when the rxipv4_nopay_frms counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0

Bit	Name	Description	Access	Reset
1	rxipv4herfim	Setting this bit masks the interrupt when the rxipv4_hdrerr_frms counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0
0	rxipv4gfim	Setting this bit masks the interrupt when the rxipv4_gd_frms counter reaches half of the maximum value or the maximum value. **Value** **Description** 0x0 counter < half max 0x1 counter >= half max or max	RW	0x0

MMC_IPC_Receive_Interrupt

This register maintains the interrupts generated when receive IPC statistic counters reach half their maximum values (0x8000_0000 for 32-bit counter and 0x8000 for 16-bit counter), and when they cross their maximum values (0xFFFF_FFFF for 32-bit counter and 0xFFFF for 16-bit counter). When Counter Stop Rollover is set, then interrupts are set but the counter remains at all-ones. The MMC Receive Checksum Offload Interrupt register is 32-bits wide. When the MMC IPC counter that caused the interrupt is read, its corresponding interrupt bit is cleared. The counter's least-significant byte lane (bits[7:0]) must be read to clear the interrupt bit.

L3_L4_Control0 Fields

Bit	Name	Description	Access	Reset
21	l4dpim0	When set, this bit indicates that the Layer 4 Destination Port number field is enabled for inverse matching. When reset, this bit indicates that the Layer 4 Destination Port number field is enabled for perfect matching. This bit is valid and applicable only when Bit 20 (L4DPM0) is set high.	RW	0x0
20	l4dpm0	When set, this bit indicates that the Layer 4 Destination Port number field is enabled for matching. When reset, the MAC ignores the Layer 4 Destination Port number field for matching.	RW	0x0
19	l4spim0	When set, this bit indicates that the Layer 4 Source Port number field is enabled for inverse matching. When reset, this bit indicates that the Layer 4 Source Port number field is enabled for perfect matching. This bit is valid and applicable only when Bit 18 (L4SPM0) is set high.	RW	0x0
18	l4spm0	When set, this bit indicates that the Layer 4 Source Port number field is enabled for matching. When reset, the MAC ignores the Layer 4 Source Port number field for matching.	RW	0x0
16	l4pen0	When set, this bit indicates that the Source and Destination Port number fields for UDP frames are used for matching. When reset, this bit indicates that the Source and Destination Port number fields for TCP frames are used for matching. The Layer 4 matching is done only when either L4SPM0 or L4DPM0 bit is set high.	RW	0x0

Bit	Name	Description	Access	Reset
15:11	l3hdbm0	IPv4 Frames: This field contains the number of higher bits of IP Destination Address that are matched in the IPv4 frames. The following list describes the values of this field: * 0: No bits are masked. * 1: LSb[0] is masked. * 2: Two LSbs [1:0] are masked. * ... * 31: All bits except MSb are masked. IPv6 Frames: Bits [12:11] of this field correspond to Bits [6:5] of L3HSBM0, which indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 frames. The following list describes the concatenated values of the L3HDBM0[1:0] and L3HSBM0 bits: * 0: No bits are masked. * 1: LSb[0] is masked. * 2: Two LSbs [1:0] are masked. * ... * 127: All bits except MSb are masked. This field is valid and applicable only if L3DAM0 or L3SAM0 is set high.	RW	0x0
10:6	l3hsbm0	IPv4 Frames: This field contains the number of lower bits of IP Source Address that are masked for matching in the IPv4 frames. The following list describes the values of this field: * 0: No bits are masked. * 1: LSb[0] is masked. * 2: Two LSbs [1:0] are masked. * ... * 31: All bits except MSb are masked. IPv6 Frames: This field contains Bits [4:0] of the field that indicates the number of higher bits of IP Source or Destination Address matched in the IPv6 frames. This field is valid and applicable only if L3DAM0 or L3SAM0 is set high.	RW	0x0
5	l3daim0	When set, this bit indicates that the Layer 3 IP Destination Address field is enabled for inverse matching. When reset, this bit indicates that the Layer 3 IP Destination Address field is enabled for perfect matching. This bit is valid and applicable only when Bit 4 (L3DAM0) is set high.	RW	0x0
4	l3dam0	When set, this bit indicates that Layer 3 IP Destination Address field is enabled for matching. When reset, the MAC ignores the Layer 3 IP Destination Address field for matching. Note: When Bit 0 (L3PEN0) is set, you should set either this bit or Bit 2 (L3SAM0) because either IPv6 DA or SA can be checked for filtering.	RW	0x0
3	l3saim0	When set, this bit indicates that the Layer 3 IP Source Address field is enabled for inverse matching. When reset, this bit indicates that the Layer 3 IP Source Address field is enabled for perfect matching. This bit is valid and applicable only when Bit 2 (L3SAM0) is set high.	RW	0x0

Bit	Name	Description	Access	Reset
2	l3sam0	When set, this bit indicates that the Layer 3 IP Source Address field is enabled for matching. When reset, the MAC ignores the Layer 3 IP Source Address field for matching. Note: When Bit 0 (L3PEN0) is set, you should set either this bit or Bit 4 (L3DAM0) because either IPv6 SA or DA can be checked for filtering.	RW	0x0
0	l3pen0	When set, this bit indicates that the Layer 3 IP Source or Destination Address matching is enabled for the IPv6 frames. When reset, this bit indicates that the Layer 3 IP Source or Destination Address matching is enabled for the IPv4 frames. The Layer 3 matching is done only when either L3SAM0 or L3DAM0 bit is set high.	RW	0x0

Layer4_Address0

Because the Layer 3 and Layer 4 Address Registers are double-synchronized to the Rx clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform the consecutive writes to the same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

L3_L4_Control3 Fields

Bit	Name	Description	Access	Reset
21	l4dpim3	When set, this bit indicates that the Layer 4 Destination Port number field is enabled for inverse matching. When reset, this bit indicates that the Layer 4 Destination Port number field is enabled for perfect matching. This bit is valid and applicable only when Bit 20 (L4DPM3) is set high.	RW	0x0

Bit	Name	Description	Access	Reset
20	l4dpm3	When set, this bit indicates that the Layer 4 Destination Port number field is enabled for matching. When reset, the MAC ignores the Layer 4 Destination Port number field for matching.	RW	0x0
19	l4spim3	When set, this bit indicates that the Layer 4 Source Port number field is enabled for inverse matching. When reset, this bit indicates that the Layer 4 Source Port number field is enabled for perfect matching. This bit is valid and applicable only when Bit 18 (L4SPM3) is set high.	RW	0x0
18	l4spm3	When set, this bit indicates that the Layer 4 Source Port number field is enabled for matching. When reset, the MAC ignores the Layer 4 Source Port number field for matching.	RW	0x0
16	l4pen3	When set, this bit indicates that the Source and Destination Port number fields for UDP frames are used for matching. When reset, this bit indicates that the Source and Destination Port number fields for TCP frames are used for matching. The Layer 4 matching is done only when either L4SPM3 or L4DPM3 bit is set high.	RW	0x0
15:11	l3hdbm3	Layer 3 IP DA Higher Bits Match IPv4 Frames: This field contains the number of higher bits of IP Destination Address that are matched in the IPv4 frames. The following list describes the values of this field: * 0: No bits are masked. * 1: LSb[0] is masked. * 2: Two LSbs [1:0] are masked. * ... * 31: All bits except MSb are masked. IPv6 Frames: Bits [12:11] of this field correspond to Bits [6:5] of L3HSBM3, which indicate the number of lower bits of IP Source or Destination Address that are masked in the IPv6 frames. The following list describes the concatenated values of the L3HDBM3[1:0] and L3HSBM3 bits: * 0: No bits are masked. * 1: LSb[0] is masked. * 2: Two LSbs [1:0] are masked. * ... * 127: All bits except MSb are masked. This field is valid and applicable only if L3DAM3 or L3SAM3 is set high.	RW	0x0

Bit	Name	Description	Access	Reset
10:6	l3hsbm3	IPv4 Frames: This field contains the number of lower bits of IP Source Address that are masked for matching in the IPv4 frames. The following list describes the values of this field: * 0: No bits are masked. * 1: LSb[0] is masked. * 2: Two LSbs [1:0] are masked. * ... * 31: All bits except MSb are masked. IPv6 Frames: This field contains Bits [4:0] of the field that indicates the number of higher bits of IP Source or Destination Address matched in the IPv6 frames. This field is valid and applicable only if L3DAM3 or L3SAM3 is set high.	RW	0x0
5	l3daim3	When set, this bit indicates that the Layer 3 IP Destination Address field is enabled for inverse matching. When reset, this bit indicates that the Layer 3 IP Destination Address field is enabled for perfect matching. This bit is valid and applicable only when Bit 4 (L3DAM3) is set high.	RW	0x0
4	l3dam3	When set, this bit indicates that Layer 3 IP Destination Address field is enabled for matching. When reset, the MAC ignores the Layer 3 IP Destination Address field for matching. Note: When Bit 0 (L3PEN3) is set, you should set either this bit or Bit 2 (L3SAM3) because either IPv6 DA or SA can be checked for filtering.	RW	0x0
3	l3saim3	When set, this bit indicates that the Layer 3 IP Source Address field is enabled for inverse matching. When reset, this bit indicates that the Layer 3 IP Source Address field is enabled for perfect matching. This bit is valid and applicable only when Bit 2 (L3SAM3) is set high.	RW	0x0
2	l3sam3	When set, this bit indicates that the Layer 3 IP Source Address field is enabled for matching. When reset, the MAC ignores the Layer 3 IP Source Address field for matching. Note: When Bit 0 (L3PEN3) is set, you should set either this bit or Bit 4 (L3DAM3) because either IPv6 SA or DA can be checked for filtering.	RW	0x0
0	l3pen3	When set, this bit indicates that the Layer 3 IP Source or Destination Address matching is enabled for the IPv6 frames. When reset, this bit indicates that the Layer 3 IP Source or Destination Address matching is enabled for the IPv4 frames. The Layer 3 matching is done only when either L3SAM3 or L3DAM3 bit is set high.	RW	0x0

Layer4_Address3

Because the Layer 3 and Layer 4 Address Registers are double-synchronized to the Rx clock domains, then the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Layer 3 and Layer 4 Address Registers are written. For proper synchronization updates, you should perform the consecutive writes to the same Layer 3 and Layer 4 Address Registers after at least four clock cycles delay of the destination clock.

Layer3_Addr3_Reg3 Fields

Bit	Name	Description	Access	Reset
31:0	l3a33	When Bit 0 (L3PEN3) and Bit 2 (L3SAM3) are set in Register 292 (Layer 3 and Layer 4 Control Register 3), this field contains the value to be matched with Bits [127:96] of the IP Source Address field in the IPv6 frames. When Bit 0 (L3PEN3) and Bit 4 (L3DAM3) are set in Register 292 (Layer 3 and Layer 4 Control Register 3), this field contains the value to be matched with Bits [127:96] of the IP Destination Address field in the IPv6 frames. When Bit 0 (L3PEN3) is reset in Register 292 (Layer 3 and Layer 4 Control Register 3), this register is not used.	RW	0x0

Hash_Table_Reg0

This register contains the first 32 bits of the hash table. The 256-bit Hash table is used for group address filtering. For hash filtering, the content of the destination address in the incoming frame is passed through the CRC logic and the upper eight bits of the CRC register are used to index the content of the Hash table. The most significant bits determines the register to be used (Hash Table Register X), and the least significant five bits determine the bit within the register. For example, a hash value of 8b'10111111 selects Bit 31 of the Hash Table Register 5. The hash value of the destination address is calculated in the following way: 1. Calculate the 32-bit CRC for the DA (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32). 2. Perform bitwise reversal for the value obtained in Step 1. 3. Take the upper 8 bits from the value obtained in Step 2. If the corresponding bit value of the register is 1'b1, the frame is accepted. Otherwise, it is rejected. If the Bit 1 (Pass All Multicast) is set in Register 1 (MAC Frame Filter), then all multicast frames are accepted regardless of the multicast hash values. Because the Hash Table register is double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the Hash Table Register X registers are written. Note: Because of double-synchronization, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

VLAN_Hash_Table_Reg

The 16-bit Hash table is used for group address filtering based on VLAN tag when Bit 18 (VTHM) of Register 7 (VLAN Tag Register) is set. For hash filtering, the content of the 16-bit VLAN tag or 12-bit VLAN ID (based on Bit 16 (ETV) of VLAN Tag Register) in the incoming frame is passed through the CRC logic and the upper four bits of the calculated CRC are used to index the contents of the VLAN Hash table. For example, a hash value of 4b'1000 selects Bit 8 of the VLAN Hash table. The hash value of the destination address is calculated in the following way: 1. Calculate the 32-bit CRC for the VLAN tag or ID (See IEEE 802.3, Section 3.2.8 for the steps to calculate CRC32). 2. Perform bitwise reversal for the value obtained in Step 1. 3. Take the upper four bits from the value obtained in Step 2. If the corresponding bit value of the register is 1'b1, the frame is accepted. Otherwise, it is rejected. Because the Hash Table register is double-synchronized to the (G)MII clock domain, the synchronization is triggered only when Bits[15:8] (in little-endian mode) or Bits[7:0] (in big-endian mode) of this register are written. Notes: * Because of double-synchronization, consecutive writes to this register should be performed after at least four clock cycles in the destination clock domain.

Timestamp_Control Fields

Bit	Name	Description	Access	Reset
25	atsen0	This field controls capturing the Auxiliary Snapshot Trigger 0. When this bit is set, the Auxiliary snapshot of event on ptp_aux_trig_i[0] input is enabled. When this bit is reset, the events on this input are ignored. **Value** **Description** 0x0 Auxiliary snapshot of event on ptp_aux_trig_i[0] input is disabled. 0x1 Auxiliary snapshot of event on ptp_aux_trig_i[0] input is enabled.	RW	0x0
24	atsfc	When set, it resets the pointers of the Auxiliary Snapshot FIFO. This bit is cleared when the pointers are reset and the FIFO is empty. When this bit is high, auxiliary snapshots get stored in the FIFO. **Value** **Description** 0x0 Don't reset Auxiliary Snapshot FIFO pointers 0x1 Reset Auxiliary Snapshot FIFO pointers	RW	0x0

Bit	Name	Description	Access	Reset
18	tsenmacaddr	When set, the DA MAC address (that matches any MAC Address register) is used to filter the PTP frames when PTP is directly sent over Ethernet. **Value** **Description** 0x0 DA MAC address doesn't filter PTP frames 0x1 DA MAC address filters PTP frames	RW	0x0
17:16	snaptypsel	These bits along with Bits 15 and 14 decide the set of PTP packet types for which snapshot needs to be taken.	RW	0x0
15	tsmstrena	When set, the snapshot is taken only for the messages relevant to the master node. Otherwise, the snapshot is taken for the messages relevant to the slave node. **Value** **Description** 0x0 Timestamp snapshot taken for messages relevant to slave node 0x1 Timestamp snapshot taken for messages relevant to master node	RW	0x0
14	tsevntena	When set, the timestamp snapshot is taken only for event messages (SYNC, Delay_Req, Pdelay_Req, or Pdelay_Resp). When reset, the snapshot is taken for all messages except Announce, Management, and Signaling. **Value** **Description** 0x0 Timestamp snapshot disabled for event messages 0x1 Timestamp snapshot only for event messages	RW	0x0
13	tsipv4ena	When set, the MAC receiver processes the PTP packets encapsulated in UDP over IPv4 packets. When this bit is clear, the MAC ignores the PTP transported over UDP-IPv4 packets. This bit is set by default. **Value** **Description** 0x0 Don't process PTP packets in UDP over IPv4 0x1 Process PTP packets in UDP over IPv4	RW	0x1

Bit	Name	Description	Access	Reset
12	tsipv6ena	When set, the MAC receiver processes PTP packets encapsulated in UDP over IPv6 packets. When this bit is clear, the MAC ignores the PTP transported over UDP-IPv6 packets. **Value** **Description** 0x0 Don't process PTP packets in UDP over IPv6 0x1 Process PTP packets in UDP over IPv6	RW	0x0
11	tsipena	When set, the MAC receiver processes the PTP packets encapsulated directly in the Ethernet frames. When this bit is clear, the MAC ignores the PTP over Ethernet packets. **Value** **Description** 0x0 Don't process PTP packets in Ethernet frames 0x1 Process PTP packets in Ethernet frames	RW	0x0
10	tsver2ena	When set, the PTP packets are processed using the 1588 version 2 format. Otherwise, the PTP packets are processed using the version 1 format. **Value** **Description** 0x0 PTP packets processed with 1588 version 1 format 0x1 PTP packets processed with 1588 version 2 format	RW	0x0
9	tsctrlssr	When set, the Timestamp Low register rolls over after 0x3B9A_C9FF value (that is, 1 nanosecond accuracy) and increments the timestamp (High) seconds. When reset, the rollover value of sub-second register is 0x7FFF_FFFF. The sub-second increment has to be programmed correctly depending on the PTP reference clock frequency and the value of this bit. **Value** **Description** 0x0 Timestamp Low register rolls over at 0x7FFF_FFFF 0x1 Timestamp Low register rolls over at 1ns	RW	0x0

Bit	Name	Description	Access	Reset
8	tsenall	When set, the timestamp snapshot is enabled for all frames received by the MAC. **Value** **Description** 0x0 Timestamp snapshot disabled 0x1 Timestamp snapshot enabled	RW	0x0
5	tsaddreg	When set, the content of the Timestamp Addend register is updated in the PTP block for fine correction. This is cleared when the update is completed. This register bit should be zero before setting it. **Value** **Description** 0x0 Timestamp Addend register is not updated 0x1 Timestamp Addend register is updated	RW	0x0
4	tstrig	When set, the timestamp interrupt is generated when the System Time becomes greater than the value written in the Target Time register. This bit is reset after the generation of the Timestamp Trigger Interrupt. **Value** **Description** 0x0 Timestamp not generated 0x1 Timestamp generated	RW	0x0
3	tsupdt	When set, the system time is updated (added or subtracted) with the value specified in Register 452 (System Time - Seconds Update Register) and Register 453 (System Time - Nanoseconds Update Register). This bit should be read zero before updating it. This bit is reset when the update is completed in hardware. The Timestamp Higher Word register is not updated. **Value** **Description** 0x0 Timestamp not updated (added or subtracted) with values in Register 452 and Register 453 0x1 Timestamp updated (added or subtracted) with values in Register 452 and Register 453	RW	0x0

Bit	Name	Description	Access	Reset
2	tsinit	When set, the system time is initialized (overwritten) with the value specified in the Register 452 (System Time - Seconds Update Register) and Register 453 (System Time - Nanoseconds Update Register). This bit should be read zero before updating it. This bit is reset when the initialization is complete. The Timestamp Higher Word register can only be initialized. **Value** **Description** 0x0 Timestamp not initialized (overwritten) by values in Register 452 and Register 453 0x1 Timestamp initialized (overwritten) by values in Register 452 and Register 453	RW	0x0
1	tscfupdt	When set, this bit indicates that the system times update should be done using the fine update method. When reset, it indicates the system timestamp update should be done using the Coarse method. **Value** **Description** 0x0 Timestamp Coarse 0x1 Timestamp Fine	RW	0x0
0	tsena	When set, the timestamp is added for the transmit and receive frames. When disabled, timestamp is not added for the transmit and receive frames and the Timestamp Generator is also suspended. You need to initialize the Timestamp (system time) after enabling this mode. On the receive side, the MAC processes the 1588 frames only if this bit is set. **Value** **Description** 0x0 Timestamp not added 0x1 Timestamp added for transmit and receive	RW	0x0

Sub_Second_Increment

In the Coarse Update mode (TSCFUPDT bit in Register 448), the value in this register is added to the system time every clock cycle of clk_ptp_ref_i. In the Fine Update mode, the value in this register is added to the system time whenever the Accumulator gets an overflow.

Module Instance	Base Address	Register Address

Sub_Second_Increment Fields

Bit	Name	Description	Access	Reset
7:0	ssinc	The value programmed in this field is accumulated every clock cycle (of clk_ptp_i) with the contents of the sub-second register. For example, when PTP clock is 50 MHz (period is 20 ns), you should program 20 (0x14) when the System Time-Nanoseconds register has an accuracy of 1 ns (TSCTRLSSR bit is set). When TSCTRLSSR is clear, the Nanoseconds register has a resolution of ~0.465ns. In this case, you should program a value of 43 (0x2B) that is derived by 20ns/0.465.	RW	0x0

System_Time_Seconds

The System Time -Seconds register, along with System-TimeNanoseconds register, indicates the current value of the system time maintained by the MAC. Though it is updated on a continuous basis, there is some delay from the actual time because of clock domain transfer latencies (from clk_ptp_ref_i to l3_sp_clk).

Target_Time_Nanoseconds Fields

Bit	Name	Description	Access	Reset
31	trgtbusy	The MAC sets this bit when the PPSCMD field (Bits[3:0]) in Register 459 (PPS Control Register) is programmed to 010 or 011. Programming the PPSCMD field to 010 or 011, instructs the MAC to synchronize the Target Time Registers to the PTP clock domain. The MAC clears this bit after synchronizing the Target Time Registers to the PTP clock domain The application must not update the Target Time Registers when this bit is read as 1. Otherwise, the synchronization of the previous programmed time gets corrupted. This bit is reserved when the Enable Flexible Pulse-Per-Second Output feature is not selected.	RO	0x0
30:0	ttslo	This register stores the time in (signed) nanoseconds. When the value of the timestamp matches the both Target Timestamp registers, then based on the TRGTMODSEL0 field (Bits [6:5]) in Register 459 (PPS Control Register), the MAC starts or stops the PPS signal output and generates an interrupt (if enabled). This value should not exceed 0x3B9A_C9FF when TSCTRLSSR is set in the Timestamp control register. The actual start or stop time of the PPS signal output may have an error margin up to one unit of sub-second increment value.	RW	0x0

PPS_Control Fields

Bit	Name	Description	Access	Reset
6:5	trgtmodsel0	This field indicates the Target Time registers (register 455 and 456) mode for PPS0 output signal **Value** **Description** 0x0 Target Time regs generate interrupt event. 0x2 Target Time gen. interr event and sig pps0 0x3 Target Time No inter just start and stop sig pps0	RW	0x0
4	ppsen0	When set low, Bits[3:0] function as PPSCTRL (backward compatible). When set high, Bits[3:0] function as PPSCMD. **Value** **Description** 0x0 Bits[3:0] function as ppsctrl0 0x1 Bits[3:0] function as ppscmd	RW	0x0

Bit	Name	Description	Access	Reset
3:0	ppsctrl_ppscmd	PPSCTRL0: PPS0 Output Frequency Control This field controls the frequency of the PPS0 output (ptp_pps_o[0]) signal. The default value of PPSCTRL is 0000, and the PPS output is 1 pulse (of width clk_ptp_i) every second. For other values of PPSCTRL, the PPS output becomes a generated clock of following frequencies: -0001: The binary rollover is 2 Hz, and the digital rollover is 1 Hz. -0010: The binary rollover is 4 Hz, and the digital rollover is 2 Hz. -0011: The binary rollover is 8 Hz, and the digital rollover is 4 Hz. -0100: The binary rollover is 16 Hz, and the digital rollover is 8 Hz. -... -1111: The binary rollover is 32.768 KHz, and the digital rollover is 16.384 KHz. Note: In the binary rollover mode, the PPS output (ptp_pps_o) has a duty cycle of 50 percent with these frequencies. In the digital rollover mode, the PPS output frequency is an average number. The actual clock is of different frequency that gets synchronized every second. For example: * When PPSCTRL = 0001, the PPS (1 Hz) has a low period of 537 ms and a high period of 463 ms * When PPSCTRL = 0010, the PPS (2 Hz) is a sequence of: - One clock of 50 percent duty cycle and 537 ms period - Second clock of 463 ms period (268 ms low and 195 ms high) * When PPSCTRL = 0011, the PPS (4 Hz) is a sequence of: - Three clocks of 50 percent duty cycle and 268 ms period - Fourth clock of 195 ms period (134 ms low and 61 ms high) This behavior is because of the non-linear toggling of bits in the digital rollover mode in Register 451 (System Time - Nanoseconds Register). Flexible PPS0 Output (ptp_pps_o[0]) Control Programming these bits with a non-zero value instructs the MAC to initiate an event. Once the command is transferred or synchronized to the PTP clock domain, these bits get cleared automatically. The Software should ensure that these bits are programmed only when they are all-zero. The following list describes the values of PPSCMD0: * 0000: No Command * 0001: START Single Pulse This command generates single pulse rising at the start point defined in Target Time Registers (register 455 and 456) and of a duration defined in the PPS0 Width Register. * 0010: START Pulse Train This command generates the train of pulses rising at the start point defined in the Target Time Registers and of a duration defined in the PPS0 Width Register and repeated at interval defined in the PPS Interval Register. By default, the PPS pulse train is free-running unless stopped by 'STOP Pulse train at time' or 'STOP Pulse Train immediately' commands. * 0011: Cancel START This command cancels the START Single Pulse and START Pulse Train commands if the system time has not crossed the programmed start time. * 0100: STOP Pulse train at by the START Pulse Train command (PPSCMD = 0010) after the time programmed in the Target Time registers elapses. * 0101: STOP Pulse Train immediately This command immediately stops the train of pulses initiated by the START Pulse Train	RW	0x0

Auxiliary_Timestamp_Nanoseconds

This register, along with Register 461 (Auxiliary Timestamp Seconds Register), gives the 64-bit timestamp stored as auxiliary snapshot. The two registers together form the read port of a 64-bit wide FIFO with a depth of 16. Multiple snapshots can be stored in this FIFO. The ATSNS bits in the Timestamp Status register indicate the fill-level of this FIFO. The top of the FIFO is removed only when the last byte of Register 461 (Auxiliary Timestamp - Seconds Register) is read. In the little-endian mode, this means when Bits[31:24] are read. In big-endian mode, it corresponds to the reading of Bits[7:0] of Register 461 (Auxiliary Timestamp - Seconds Register).

PPS0_Width Fields

Bit	Name	Description	Access	Reset
31:0	ppswidth	These bits store the width between the rising edge and corresponding falling edge of the PPS0 signal output in terms of units of sub-second increment value. You need to program one value less than the required interval. For example, if PTP reference clock is 50 MHz (period of 20ns), and desired width between the rising and corresponding falling edges of PPS0 signal output is 80ns (that is, four units of sub-second increment value), then you should program value 3 (4-1) in this register. Note: The value programmed in this register must be lesser than the value programmed in Register 472 (PPS0 Interval Register).	RW	0x0

MAC_Address16_High

The MAC Address16 High register holds the upper 16 bits of the 17th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address16 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

31:0	addrlo	This field contains the lower 32 bits of the 20th 6-byte MAC address. The content of this field is undefined until loaded by software after the initialization process.	RW	0xFFFFFFFF

MAC_Address20_High

The MAC Address20 High register holds the upper 16 bits of the 21th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address20 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700820
emac1	0xFF702000	0xFF702820

MAC_Address25_High

The MAC Address25 High register holds the upper 16 bits of the 26th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address25 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address28_High Fields

Bit	Name	Description	Access	Reset
31	ae	When this bit is enabled, the address filter block uses the 29th MAC address for perfect filtering. When this bit is disabled, the address filter block ignores the address for filtering. **Value** **Description** 0x0 Second MAC address filtering disabled 0x1 Second MAC address filtering enabled	RW	0x0
30	sa	When this bit is enabled, the MAC Address28[47:0] is used to compare with the SA fields of the received frame. When this bit is disabled, the MAC Address28[47:0] is used to compare with the DA fields of the received frame. **Value** **Description** 0x0 MAC address compare disabled 0x1 MAC address compare enabled	RW	0x0
29	mbc_5	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address28 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0

Bit	Name	Description	Access	Reset
28	mbc_4	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address28 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
27	mbc_3	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address28 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
26	mbc_2	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address28 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0

Bit	Name	Description	Access	Reset
25	mbc_1	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address28 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
24	mbc_0	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address28 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
15:0	addrhi	This field contains the upper 16 bits (47:32) of the 29th 6-byte MAC address.	RW	0xFFFF

MAC_Address28_Low

The MAC Address28 Low register holds the lower 32 bits of the 29th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700864
emac1	0xFF702000	0xFF702864

31:0	addrlo	This field contains the lower 32 bits of the 29th 6-byte MAC address. The content of this field is undefined until loaded by software after the initialization process.	RW	0xFFFFFFFF

MAC_Address29_High

The MAC Address29 High register holds the upper 16 bits of the 30th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address29 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

MAC_Address33_High

The MAC Address33 High register holds the upper 16 bits of the 34th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address33 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address37_High

The MAC Address37 High register holds the upper 16 bits of the 38th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address37 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address41_High

The MAC Address41 High register holds the upper 16 bits of the 42th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address41 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address45_High

The MAC Address45 High register holds the upper 16 bits of the 46th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address45 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address49_High

The MAC Address49 High register holds the upper 16 bits of the 50th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address49 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address53_High

The MAC Address53 High register holds the upper 16 bits of the 54th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address53 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Bit	Name	Description	Access	Reset
31:0	addrlo	This field contains the lower 32 bits of the 57th 6-byte MAC address. The content of this field is undefined until loaded by software after the initialization process.	RW	0xFFFFFFFF

MAC_Address57_High

The MAC Address57 High register holds the upper 16 bits of the 58th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address57 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address61_High

The MAC Address61 High register holds the upper 16 bits of the 62th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address61 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

MAC_Address65_High Fields

Bit	Name	Description	Access	Reset
31	ae	When this bit is enabled, the address filter block uses the 66th MAC address for perfect filtering. When this bit is disabled, the address filter block ignores the address for filtering. **Value** **Description** 0x0 Second MAC address filtering disabled 0x1 Second MAC address filtering enabled	RW	0x0
30	sa	When this bit is enabled, the MAC Address65[47:0] is used to compare with the SA fields of the received frame. When this bit is disabled, the MAC Address65[47:0] is used to compare with the DA fields of the received frame. **Value** **Description** 0x0 MAC address compare disabled 0x1 MAC address compare enabled	RW	0x0
29	mbc_5	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address65 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0

Bit	Name	Description	Access	Reset
28	mbc_4	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address65 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
27	mbc_3	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address65 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
26	mbc_2	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address65 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0

Bit	Name	Description	Access	Reset
25	mbc_1	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address65 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
24	mbc_0	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address65 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
15:0	addrhi	This field contains the upper 16 bits (47:32) of the 66th 6-byte MAC address.	RW	0xFFFF

MAC_Address65_Low

The MAC Address65 Low register holds the lower 32 bits of the 66th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

Module Instance	Base Address	Register Address

MAC_Address66_High

The MAC Address66 High register holds the upper 16 bits of the 67th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address66 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address70_High

The MAC Address70 High register holds the upper 16 bits of the 71th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address70 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address74_High

The MAC Address74 High register holds the upper 16 bits of the 75th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address74 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

MAC_Address78_High

The MAC Address78 High register holds the upper 16 bits of the 79th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address78 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

MAC_Address82_High

The MAC Address82 High register holds the upper 16 bits of the 83th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address82 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address86_High

The MAC Address86 High register holds the upper 16 bits of the 87th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address86 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address90_High

The MAC Address90 High register holds the upper 16 bits of the 91th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address90 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address94_High

The MAC Address94 High register holds the upper 16 bits of the 95th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address94 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

Bit	Name	Description	Access	Reset
31:0	addrlo	This field contains the lower 32 bits of the 98th 6-byte MAC address. The content of this field is undefined until loaded by software after the initialization process.	RW	0xFFFFFFFF

MAC_Address98_High

The MAC Address98 High register holds the upper 16 bits of the 99th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address98 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address102_High

The MAC Address102 High register holds the upper 16 bits of the 103th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address102 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700AB0

MAC_Address110_High Fields

Bit	Name	Description	Access	Reset
31	ae	When this bit is enabled, the address filter block uses the 111th MAC address for perfect filtering. When this bit is disabled, the address filter block ignores the address for filtering. **Value** **Description** 0x0 Second MAC address filtering disabled 0x1 Second MAC address filtering enabled	RW	0x0
30	sa	When this bit is enabled, the MAC Address110[47:0] is used to compare with the SA fields of the received frame. When this bit is disabled, the MAC Address110[47:0] is used to compare with the DA fields of the received frame. **Value** **Description** 0x0 MAC address compare disabled 0x1 MAC address compare enabled	RW	0x0
29	mbc_5	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address110 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0

Bit	Name	Description	Access	Reset
28	mbc_4	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address110 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
27	mbc_3	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address110 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
26	mbc_2	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address110 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0

Bit	Name	Description	Access	Reset
25	mbc_1	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address110 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
24	mbc_0	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address110 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
15:0	addrhi	This field contains the upper 16 bits (47:32) of the 111th 6-byte MAC address.	RW	0xFFFF

MAC_Address110_Low

The MAC Address110 Low register holds the lower 32 bits of the 111th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF700AF4

MAC_Address111_High

The MAC Address111 High register holds the upper 16 bits of the 112th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address111 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

Module Instance	Base Address	Register Address

MAC_Address114_High Fields

Bit	Name	Description	Access	Reset
31	ae	When this bit is enabled, the address filter block uses the 115th MAC address for perfect filtering. When this bit is disabled, the address filter block ignores the address for filtering. **Value** **Description** 0x0 Second MAC address filtering disabled 0x1 Second MAC address filtering enabled	RW	0x0
30	sa	When this bit is enabled, the MAC Address114[47:0] is used to compare with the SA fields of the received frame. When this bit is disabled, the MAC Address114[47:0] is used to compare with the DA fields of the received frame. **Value** **Description** 0x0 MAC address compare disabled 0x1 MAC address compare enabled	RW	0x0
29	mbc_5	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address114 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0

Bit	Name	Description	Access	Reset
28	mbc_4	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address114 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
27	mbc_3	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address114 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
26	mbc_2	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address114 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0

Bit	Name	Description	Access	Reset
25	mbc_1	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address114 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
24	mbc_0	This array of bits are mask control bits for comparison of each of the MAC Address bytes. When masked, the MAC does not compare the corresponding byte of received DA or SA with the contents of MAC Address114 high and low registers. Each bit controls the masking of the bytes. You can filter a group of addresses (known as group address filtering) by masking one or more bytes of the address. The array index corresponds to the byte (e.g. index 0 is for bits 7:0). **Value** **Description** 0x0 Byte is unmasked (i.e. is compared) 0x1 Byte is masked (i.e. not compared)	RW	0x0
15:0	addrhi	This field contains the upper 16 bits (47:32) of the 115th 6-byte MAC address.	RW	0xFFFF

MAC_Address114_Low

The MAC Address114 Low register holds the lower 32 bits of the 115th 6-byte MAC address of the station. Note that all MAC Address Low registers (except MAC Address0 Low) have the same format.

Module Instance	Base Address	Register Address

MAC_Address115_High

The MAC Address115 High register holds the upper 16 bits of the 116th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address115 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address119_High

The MAC Address119 High register holds the upper 16 bits of the 120th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address119 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address123_High

The MAC Address123 High register holds the upper 16 bits of the 124th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address123 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

MAC_Address127_High

The MAC Address127 High register holds the upper 16 bits of the 128th 6-byte MAC address of the station. Because the MAC address registers are configured to be double-synchronized to the (G)MII clock domains, the synchronization is triggered only when bits[31:24] (in little-endian mode) or Bits[7:0] (in big-endian mode) of the MAC Address127 Low Register are written. For proper synchronization updates, the consecutive writes to this Address Low Register should be performed after at least four clock cycles in the destination clock domain. Note that all MAC Address High registers (except MAC Address0 High) have the same format.

DMA Register Group Register Descriptions

DMA Register Group

Offset: 0x1000

Bus_Mode on page 17-816
The Bus Mode register establishes the bus operating modes for the DMA.

Transmit_Poll_Demand on page 17-819
The Transmit Poll Demand register enables the Tx DMA to check whether or not the DMA owns the current descriptor. The Transmit Poll Demand command is given to wake up the Tx DMA if it is in the Suspend mode. The Tx DMA can go into the Suspend mode because of an Underflow error in a transmitted frame or the unavailability of descriptors owned by it. You can give this command anytime and the Tx DMA resets this command when it again starts fetching the current descriptor from host memory.

Receive_Poll_Demand on page 17-820
The Receive Poll Demand register enables the receive DMA to check for new descriptors. This command is used to wake up the Rx DMA from the SUSPEND state. The RxDMA can go into the SUSPEND state only because of the unavailability of descriptors it owns.

Receive_Descriptor_List_Address on page 17-821
The Receive Descriptor List Address register points to the start of the Receive Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, Bit 1 (SR) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the SR bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

Transmit_Descriptor_List_Address on page 17-822
The Transmit Descriptor List Address register points to the start of the Transmit Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LSB to low. You can write to this register only when the Tx DMA has stopped, that is, Bit 13 (ST) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the ST bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the ST bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

Status on page 17-822
The Status register contains all status bits that the DMA reports to the host. The software driver reads this register during an interrupt service routine or polling. Most of the fields in this register cause the host to be interrupted. The bits of this register are not cleared when read. Writing 1'b1 to (unreserved) Bits[16:0] of this register clears these bits and writing 1'b0 has no effect. Each field (Bits[16:0]) can be masked by masking the appropriate bit in Register 7 (Interrupt Enable Register).

Operation_Mode on page 17-828
The Operation Mode register establishes the Transmit and Receive operating modes and commands. This register should be the last CSR to be written as part of the DMA initialization.

Interrupt_Enable on page 17-834
The Interrupt Enable register enables the interrupts reported by Register 5 (Status Register). Setting a bit to 1'b1 enables a corresponding interrupt. After a hardware or software reset, all interrupts are disabled.

Missed_Frame_And_Buffer_Overflow_Counter on page 17-838
The DMA maintains two counters to track the number of frames missed during reception. This register reports the current value of the counter. The counter is used for diagnostic purposes. Bits[15:0] indicate missed frames because of the host buffer being unavailable. Bits[27:17] indicate missed frames because of buffer overflow conditions (MTL and MAC) and runt frames (good frames of less than 64 bytes) dropped by the MTL.

Receive_Interrupt_Watchdog_Timer on page 17-839
This register, when written with non-zero value, enables the watchdog timer for the Receive Interrupt (Bit 6) of Register 5 (Status Register)

AXI_Bus_Mode on page 17-840
The AXI Bus Mode Register controls the behavior of the AXI master. It is mainly used to control the burst splitting and the number of outstanding requests.

AHB_or_AXI_Status on page 17-843
This register provides the active status of the AXI interface's read and write channels. This register is useful for debugging purposes.

Current_Host_Transmit_Descriptor on page 17-844
The Current Host Transmit Descriptor register points to the start address of the current Transmit Descriptor read by the DMA.

Current_Host_Receive_Descriptor on page 17-844
The Current Host Receive Descriptor register points to the start address of the current Receive Descriptor read by the DMA.

Current_Host_Transmit_Buffer_Address on page 17-845
The Current Host Transmit Buffer Address register points to the current Transmit Buffer Address being read by the DMA.

Current_Host_Receive_Buffer_Address on page 17-845
The Current Host Receive Buffer Address register points to the current Receive Buffer address being read by the DMA.

HW_Feature on page 17-846
This register indicates the presence of the optional features or functions of the gmac. The software driver can use this register to dynamically enable or disable the programs related to the optional blocks.

Bus_Mode

The Bus Mode register establishes the bus operating modes for the DMA.

Module Instance	Base Address	Register Address

Bus_Mode Fields

Bit	Name	Description	Access	Reset
25	aal	When this bit is set high and the FB bit is equal to 1, the AHB or AXI interface generates all bursts aligned to the start address LS bits. If the FB bit is equal to 0, the first burst (accessing the data buffer's start address) is not aligned, but subsequent bursts are aligned to the address. **Value** — **Description** 0x0 — No Address-Aligned Beats 0x1 — Address-Aligned Beats (dependent on FB)	RW	0x0

Bit	Name	Description	Access	Reset
24	eightxpbl	When set high, this bit multiplies the programmed PBL value (Bits[22:17] and Bits[13:8]) eight times. Therefore, the DMA transfers the data in 8, 16, 32, 64, 128, and 256 beats depending on the PBL value. **Value** **Description** 0x0 Non Multiply Mode 0x1 Multiplies PBL value by 8	RW	0x0
23	usp	When set high, this bit configures the Rx DMA to use the value configured in Bits[22:17] as PBL. The PBL value in Bits[13:8] is applicable only to the Tx DMA operations. When reset to low, the PBL value in Bits[13:8] is applicable for both DMA engines. **Value** **Description** 0x0 Configures TX RX DMA to PBL 0x1 Configures TX DMA to PBL	RW	0x0
22:17	rpbl	This field indicates the maximum number of beats to be transferred in one Rx DMA transaction. This is the maximum value that is used in a single block Read or Write. The Rx DMA always attempts to burst as specified in the RPBL bit each time it starts a Burst transfer on the host bus. You can program RPBL with values of 1, 2, 4, 8, 16, and 32. Any other value results in undefined behavior. This field is valid and applicable only when USP is set high. **Value** **Description** 0x1 Beats Trans. in one Rx DMA Transaction 0x2 Beats Trans. in one Rx DMA Transaction 0x4 Beats Trans. in one Rx DMA Transaction 0x8 Beats Trans. in one Rx DMA Transaction 0x10 Beats Trans. in one Rx DMA Transaction 0x20 Beats Trans. in one Rx DMA Transaction	RW	0x1

Bit	Name	Description	Access	Reset
16	fb	This bit controls whether the AXI Master interface performs fixed burst transfers or not. When set, the AXI interface uses FIXED bursts during the start of the normal burst transfers. When reset, the AXI interface uses SINGLE and INCR burst transfer operations. For more information, see Bit 0 (UNDEFINED) of the AXI Bus Mode register. **Value** — **Description** 0x0 — SINGLE or INCR Burst 0x1 — FIXED Burst (1, 4, 8, or 16)	RW	0x0
13:8	pbl	These bits indicate the maximum number of beats to be transferred in one DMA transaction. This is the maximum value that is used in a single block Read or Write. The DMA always attempts to burst as specified in PBL each time it starts a Burst transfer on the host bus. PBL can be programmed with permissible values of 1, 2, 4, 8, 16, and 32. Any other value results in undefined behavior. When USP is set high, this PBL value is applicable only for Tx DMA transactions. If the number of beats to be transferred is more than 32, then perform the following steps: 1. Set the 8xPBL mode. 2. Set the PBL. For example, if the maximum number of beats to be transferred is 64, then first set 8xPBL to 1 and then set PBL to 8. The PBL values have the following limitation: The maximum number of possible beats (PBL) is limited by the size of the Tx FIFO and Rx FIFO in the MTL layer and the data bus width on the DMA. The FIFO has a constraint that the maximum beat supported is half the depth of the FIFO, except when specified.	RW	0x1
7	atds	When set, the size of the alternate (enhanced) descriptor increases to 32 bytes (8 DWORDS). When clear, the alternate (enhanced) descriptor size is 16 bytes (4 DWORDS). **Value** — **Description** 0x0 — Descriptor size is 16 bytes (4 DWORDS) 0x1 — Descriptor size is 32 bytes (8 DWORDS)	RW	0x0

Bit	Name	Description	Access	Reset
6:2	dsl	This bit specifies the number of Word, Dword, or Lword (depending on the 32-bit, 64-bit, or 128-bit bus) to skip between two unchained descriptors. The address skipping starts from the end of current descriptor to the start of next descriptor. When the DSL value is equal to zero, then the descriptor table is taken as contiguous by the DMA in Ring mode.	RW	0x0
0	swr	When this bit is set, the MAC DMA Controller resets the logic and all internal registers of the MAC. It is cleared automatically after the reset operation has completed in all of the EMAC clock domains. Before reprogramming any register of the EMAC, you should read a zero (0) value in this bit . Note: * The Software reset function is driven only by this bit. * The reset operation is completed only when all resets in all active clock domains are de-asserted. Therefore, it is essential that all the PHY inputs clocks (applicable for the selected PHY interface) are present for the software reset completion. **Value** **Description** 0x0 MAC DMA Controller Clears Logic 0x1 MAC DMA Controller Resets Logic	RW	0x1

Transmit_Poll_Demand

The Transmit Poll Demand register enables the Tx DMA to check whether or not the DMA owns the current descriptor. The Transmit Poll Demand command is given to wake up the Tx DMA if it is in the Suspend mode. The Tx DMA can go into the Suspend mode because of an Underflow error in a transmitted frame or the unavailability of descriptors owned by it. You can give this command anytime and the Tx DMA resets this command when it again starts fetching the current descriptor from host memory.

Receive_Poll_Demand Fields

Bit	Name	Description	Access	Reset
31:0	rpd	When these bits are written with any value, the DMA reads the current descriptor pointed to by Register 19 (Current Host Receive Descriptor Register). If that descriptor is not available (owned by the Host), the reception returns to the Suspended state and the Bit 7 (RU) of Register 5 (Status Register) is not asserted. If the descriptor is available, the Rx DMA returns to the active state.	RW	0x0

Receive_Descriptor_List_Address

The Receive Descriptor List Address register points to the start of the Receive Descriptor List. The descriptor lists reside in the host's physical memory space and must be Word, Dword, or Lword-aligned (for 32-bit, 64-bit, or 128-bit data bus). The DMA internally converts it to bus width aligned address by making the corresponding LS bits low. Writing to this register is permitted only when reception is stopped. When stopped, this register must be written to before the receive Start command is given. You can write to this register only when Rx DMA has stopped, that is, Bit 1 (SR) is set to zero in Register 6 (Operation Mode Register). When stopped, this register can be written with a new descriptor list address. When you set the SR bit to 1, the DMA takes the newly programmed descriptor base address. If this register is not changed when the SR bit is set to 0, then the DMA takes the descriptor address where it was stopped earlier.

Status

The Status register contains all status bits that the DMA reports to the host. The software driver reads this register during an interrupt service routine or polling. Most of the fields in this register cause the host to

be interrupted. The bits of this register are not cleared when read. Writing 1'b1 to (unreserved) Bits[16:0] of this register clears these bits and writing 1'b0 has no effect. Each field (Bits[16:0]) can be masked by masking the appropriate bit in Register 7 (Interrupt Enable Register).

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF701014
emac1	0xFF702000	0xFF703014

Status Fields

Bit	Name	Description	Access	Reset
30	glpii	This bit indicates an interrupt event in the LPI logic of the EMAC. To reset this bit to 1'b0, the software must read the corresponding registers in the EMAC to get the exact cause of the interrupt and clear its source. When this bit is high, the interrupt signal from the MAC (sbd_intr_o) is high. **Value** — **Description** 0x0 — No Interrupt 0x1 — GMAC LPI Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
29	tti	This bit indicates an interrupt event in the Timestamp Generator block of EMAC. The software must read the corresponding registers in the EMAC to get the exact cause of interrupt and clear its source to reset this bit to 1'b0. When this bit is high, the interrupt signal from the EMAC subsystem (sbd_intr_o) is high. **Value** **Description** 0x0 No Interrupt 0x1 Timestamp Trigger Interrupt	RO	0x0
27	gmi	This bit reflects an interrupt event in the MMC block of the EMAC. The software must read the corresponding registers in the EMAC to get the exact cause of interrupt and clear the source of interrupt to make this bit as 1'b0. The interrupt signal from the EMAC subsystem (sbd_intr_o) is high when this bit is high. **Value** **Description** 0x0 No Interrupt 0x1 GMAC MMC Interrupt	RO	0x0
26	gli	This bit reflects an interrupt event in the PCS (link change and AN complete), SMII (link change), or RGMII (link change) interface block of the EMAC. The software must read the corresponding registers (Register 49 for PCS or Register 54 for SMII or RGMII) in the EMAC to get the exact cause of the interrupt and clear the source of interrupt to make this bit as 1'b0. The interrupt signal from the EMAC subsystem (sbd_intr_o) is high when this bit is high. **Value** **Description** 0x0 No Interrupt 0x1 GMAC Line Interrupt	RO	0x0

Bit	Name	Description	Access	Reset
25:23	eb	This field indicates the type of error that caused a Bus Error, for example, error response on the AHB or AXI interface. This field is valid only when Bit 13 (FBI) is set. This field does not generate an interrupt. * Bit 23 - 1'b1: Error during data transfer by the Tx DMA - 1'b0: Error during data transfer by the Rx DMA * Bit 24 - 1'b1: Error during read transfer - 1'b0: Error during write transfer * Bit 25 - 1'b1: Error during descriptor access - 1'b0: Error during data buffer access	RO	0x0
22:20	ts	This field indicates the Transmit DMA FSM state. This field does not generate an interrupt. **Value** — **Description** 0x0 — Stopped Reset or Stop Transmit Command 0x1 — Running: Fetching Tranmit Transfer Descriptor 0x2 — Running; Waiting for status 0x3 — Running; Reading Data host memory buffer and queuing it to transmit buffer (Tx FIFO) 0x4 — TIME_STAMP write state 0x5 — Reserved for future use 0x6 — Suspended; Transmit Descriptor Unavailable or Transmit Buffer Underflow 0x7 — Running; Closing Transmit Descriptor	RO	0x0
19:17	rs	This field indicates the Receive DMA FSM state. This field does not generate an interrupt. **Value** — **Description** 0x0 — Stopped Reset or Stop Receive Command issued 0x1 — Running: Fetching Receive Transfer Descriptor 0x2 — Reserved for future use 0x3 — Running: Waiting for receive packet 0x4 — Suspended: Receive Descriptor Unavailable 0x5 — Running: Closing Receive Descriptor 0x6 — TIME_STAMP write state 0x7 — Transferring rcv packet data from receive buffer to host memory	RO	0x0

Bit	Name	Description	Access	Reset
16	nis	Normal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in Register 7 (Interrupt Enable Register): * Register 5[0]: Transmit Interrupt * Register 5[2]: Transmit Buffer Unavailable * Register 5[6]: Receive Interrupt * Register 5[14]: Early Receive Interrupt Only unmasked bits (interrupts for which interrupt enable is set in Register 7) affect the Normal Interrupt Summary bit. This is a sticky bit and must be cleared (by writing 1 to this bit) each time a corresponding bit, which causes NIS to be set, is cleared.	RW	0x0
15	ais	Abnormal Interrupt Summary bit value is the logical OR of the following when the corresponding interrupt bits are enabled in Register 7 (Interrupt Enable Register): * Register 5[1]: Transmit Process Stopped * Register 5[3]: Transmit Jabber Timeout * Register 5[4]: Receive FIFO Overflow * Register 5[5]: Transmit Underflow * Register 5[7]: Receive Buffer Unavailable * Register 5[8]: Receive Process Stopped * Register 5[9]: Receive Watchdog Timeout * Register 5[10]: Early Transmit Interrupt * Register 5[13]: Fatal Bus Error Only unmasked bits affect the Abnormal Interrupt Summary bit. This is a sticky bit and must be cleared each time a corresponding bit, which causes AIS to be set, is cleared.	RW	0x0
14	eri	This bit indicates that the DMA had filled the first data buffer of the packet. Bit 6 (RI) of this register automatically clears this bit.	RW	0x0
13	fbi	This bit indicates that a bus error occurred, as described in Bits[25:23]. When this bit is set, the corresponding DMA engine disables all of its bus accesses.	RW	0x0
10	eti	This bit indicates that the frame to be transmitted is fully transferred to the MTL Transmit FIFO.	RW	0x0
9	rwt	This bit is asserted when a frame with length greater than 2,048 bytes is received (10, 240 when Jumbo Frame mode is enabled).	RW	0x0
8	rps	This bit is asserted when the Receive Process enters the Stopped state.	RW	0x0

Bit	Name	Description	Access	Reset
7	ru	This bit indicates that the host owns the Next Descriptor in the Receive List and the DMA cannot acquire it. The Receive Process is suspended. To resume processing Receive descriptors, the host should change the ownership of the descriptor and issue a Receive Poll Demand command. If no Receive Poll Demand is issued, the Receive Process resumes when the next recognized incoming frame is received. This bit is set only when the previous Receive Descriptor is owned by the DMA.	RW	0x0
6	ri	This bit indicates that the frame reception is complete. When reception is complete, the Bit 31 of RDES1 (Disable Interrupt on Completion) is reset in the last Descriptor, and the specific frame status information is updated in the descriptor. The reception remains in the Running state.	RW	0x0
5	unf	This bit indicates that the Transmit Buffer had an Underflow during frame transmission. Transmission is suspended and an Underflow Error TDES0[1] is set.	RW	0x0
4	ovf	This bit indicates that the Receive Buffer had an Overflow during frame reception. If the partial frame is transferred to the application, the overflow status is set in RDES0[11].	RW	0x0
3	tjt	This bit indicates that the Transmit Jabber Timer expired, which happens when the frame size exceeds 2,048 (10,240 bytes when the Jumbo frame is enabled) . When the Jabber Timeout occurs, the transmission process is aborted and placed in the Stopped state. This causes the Transmit Jabber Timeout TDES0[14] flag to assert.	RW	0x0
2	tu	This bit indicates that the host owns the Next Descriptor in the Transmit List and the DMA cannot acquire it. Transmission is suspended. Bits[22:20] explain the Transmit Process state transitions. To resume processing Transmit descriptors, the host should change the ownership of the descriptor by setting TDES0[31] and then issue a Transmit Poll Demand command.	RW	0x0
1	tps	This bit is set when the transmission is stopped.	RW	0x0

Bit	Name	Description	Access	Reset
0	ti	This bit indicates that the frame transmission is complete. When transmission is complete, the Bit 31 (Interrupt on Completion) of TDES1 is reset in the first descriptor, and the specific frame status information is updated in the descriptor.	RW	0x0

Operation_Mode

The Operation Mode register establishes the Transmit and Receive operating modes and commands. This register should be the last CSR to be written as part of the DMA initialization.

Module Instance	Base Address	Register Address
emac0	0xFF700000	0xFF701018
emac1	0xFF702000	0xFF703018

Operation_Mode Fields

Bit	Name	Description	Access	Reset
26	dt	When this bit is set, the MAC does not drop the frames which only have errors detected by the Receive Checksum Offload engine. Such frames do not have any errors (including FCS error) in the Ethernet frame received by the MAC but have errors only in the encapsulated payload. When this bit is reset, all error frames are dropped if the FEF bit is reset. **Value** **Description** 0x0 All Error Frames Dropped 0x1 MAC does not drop frame with errors	RW	0x0

Bit	Name	Description	Access	Reset
25	rsf	When this bit is set, the MTL reads a frame from the Rx FIFO only after the complete frame has been written to it, ignoring the RTC bits. When this bit is reset, the Rx FIFO operates in the cut-through mode, subject to the threshold specified by the RTC bits. **Value** **Description** 0x0 Rx Fifo cut-through mode 0x1 Read Rx FIFO only after complete frame	RW	0x0
24	dff	When this bit is set, the Rx DMA does not flush any frames because of the unavailability of receive descriptors or buffers as it does normally when this bit is reset. **Value** **Description** 0x0 Rx DMA Flushed 0x1 Rx DMA not Flushed	RW	0x0
21	tsf	When this bit is set, transmission starts when a full frame resides in the MTL Transmit FIFO. When this bit is set, the TTC values specified in Bits[16:14] are ignored. This bit should be changed only when the transmission is stopped. **Value** **Description** 0x0 Tx Does not Start with Full Frame 0x1 Tx Start with Full Frame	RW	0x0

Bit	Name	Description	Access	Reset
20	ftf	When this bit is set, the transmit FIFO controller logic is reset to its default values and thus all data in the Tx FIFO is lost or flushed. This bit is cleared internally when the flushing operation is completed. The Operation Mode register should not be written to until this bit is cleared. The data which is already accepted by the MAC transmitter is not flushed. It is scheduled for transmission and results in underflow and runt frame transmission. Note: The flush operation is complete only when the Tx FIFO is emptied of its contents and all the pending Transmit Status of the transmitted frames are accepted by the host. To complete this flush operation, the PHY transmit clock is required to be active. **Value** — **Description** 0x0 — Tx FIFO Data not Flushed 0x1 — TX FIFO Data Flushed	RW	0x0
16:14	ttc	These bits control the threshold level of the MTL Transmit FIFO. Transmission starts when the frame size within the MTL Transmit FIFO is larger than the threshold. In addition, full frames with a length less than the threshold are also transmitted. These bits are used only when Bit 21 (TSF) is reset. **Value** — **Description** 0x0 — MTL Transmit FIFO Threshold 64 0x1 — MTL Transmit FIFO Threshold 128 0x2 — MTL Transmit FIFO Threshold 192 0x3 — MTL Transmit FIFO Threshold 256 0x4 — MTL Transmit FIFO Threshold 40 0x5 — MTL Transmit FIFO Threshold 32 0x6 — MTL Transmit FIFO Threshold 24 0x7 — MTL Transmit FIFO Threshold 16	RW	0x0

Bit	Name	Description	Access	Reset
13	st	When this bit is set, transmission is placed in the Running state, and the DMA checks the Transmit List at the current position for a frame to be transmitted. Descriptor acquisition is attempted either from the current position in the list, which is the Transmit List Base Address set by Register 4 (Transmit Descriptor List Address Register), or from the position retained when transmission was stopped previously. If the DMA does not own the current descriptor, transmission enters the Suspended state and Bit 2 (Transmit Buffer Unavailable) of Register 5 (Status Register) is set. The Start Transmission command is effective only when transmission is stopped. If the command is issued before setting Register 4 (Transmit Descriptor List Address Register), then the DMA behavior is unpredictable. When this bit is reset, the transmission process is placed in the Stopped state after completing the transmission of the current frame. The Next Descriptor position in the Transmit List is saved, and it becomes the current position when transmission is restarted. To change the list address, you need to program Register 4 (Transmit Descriptor List Address Register) with a new value when this bit is reset. The new value is considered when this bit is set again. The stop transmission command is effective only when the transmission of the current frame is complete or the transmission is in the Suspended state. **Value** — **Description** 0x0 — Transmission Stopped State 0x1 — Transmission in Run State	RW	0x0
12:11	rfd	These bits control the threshold (Fill-level of Rx FIFO) at which the flow control is de-asserted after activation. The de-assertion is effective only after flow control is asserted. **Value** — **Description** 0x0 — Full minus 1 KB 0x1 — Full minus 2 KB 0x2 — Full minus 3 KB 0x3 — Full minus 4 KB	RW	0x0

Bit	Name	Description	Access	Reset
10:9	rfa	These bits control the threshold (Fill level of Rx FIFO) at which the flow control is activated. These values only apply to the Rx FIFO when the EFC bit is set high. **Value** **Description** 0x0 Full minus 1 KB 0x1 Full minus 2 KB 0x2 Full minus 3 KB 0x3 Full minus 4 KB	RW	0x0
8	efc	When this bit is set, the flow control signal operation based on the fill-level of Rx FIFO is enabled. When reset, the flow control operation is disabled. **Value** **Description** 0x0 Rx FIFO Fill Level Disabled 0x1 Rx FIFO Fill Level Enabled Ctrl	RW	0x0
7	fef	When this bit is reset, the Rx FIFO drops frames with error status (CRC error, collision error, GMII_ER, giant frame, watchdog timeout, or overflow). However, if the start byte (write) pointer of a frame is already transferred to the read controller side (in Threshold mode), then the frame is not dropped. When the FEF bit is set, all frames except runt error frames are forwarded to the DMA. If the Bit 25 (RSF) is set and the Rx FIFO overflows when a partial frame is written, then the frame is dropped irrespective of the FEF bit setting. However, if the Bit 25 (RSF) is reset and the Rx FIFO overflows when a partial frame is written, then a partial frame may be forwarded to the DMA. **Value** **Description** 0x0 Drops Frames with error status 0x1 Forward all Frames(except runt)	RW	0x0

Bit	Name	Description	Access	Reset
6	fuf	When set, the Rx FIFO forwards Undersized frames (frames with no Error and length less than 64 bytes) including pad-bytes and CRC. When reset, the Rx FIFO drops all frames of less than 64 bytes, unless a frame is already transferred because of the lower value of Receive Threshold, for example, RTC = 01. **Value** **Description** 0x0 Drops Frames less than 64Bytes 0x1 Forward Frames with no errors	RW	0x0
4:3	rtc	These two bits control the threshold level of the MTL Receive FIFO. Transfer (request) to DMA starts when the frame size within the MTL Receive FIFO is larger than the threshold. In addition, full frames with length less than the threshold are transferred automatically. These bits are valid only when the RSF bit is zero, and are ignored when the RSF bit is set to 1. **Value** **Description** 0x0 MTL Rcv Fifo threshold level 64 0x1 MTL Rcv Fifo threshold level 32 0x2 MTL Rcv Fifo threshold level 96 0x3 MTL Rcv Fifo threshold level 128	RW	0x0
2	osf	When this bit is set, it instructs the DMA to process the second frame of the Transmit data even before the status for the first frame is obtained. **Value** **Description** 0x0 DMA Does Not Process second frame 0x1 DMA Processes second frame	RW	0x0

Bit	Name	Description	Access	Reset
1	sr	When this bit is set, the Receive process is placed in the Running state. The DMA attempts to acquire the descriptor from the Receive list and processes the incoming frames. The descriptor acquisition is attempted from the current position in the list, which is the address set by Register 3 (Receive Descriptor List Address Register) or the position retained when the Receive process was previously stopped. If the DMA does not own the descriptor, reception is suspended and Bit 7 (Receive Buffer Unavailable) of Register 5 (Status Register) is set. The Start Receive command is effective only when the reception has stopped. If the command is issued before setting Register 3 (Receive Descriptor List Address Register), the DMA behavior is unpredictable. When this bit is cleared, the Rx DMA operation is stopped after the transfer of the current frame. The next descriptor position in the Receive list is saved and becomes the current position after the Receive process is restarted. The Stop Receive command is effective only when the Receive process is in either the Running (waiting for receive packet) or in the Suspended state. **Value** **Description** 0x0 Rx DMA operation is stopped 0x1 Rx DMA operation is started	RW	0x0

Interrupt_Enable

The Interrupt Enable register enables the interrupts reported by Register 5 (Status Register). Setting a bit to 1'b1 enables a corresponding interrupt. After a hardware or software reset, all interrupts are disabled.

Module Instance	Base Address	Register Address

5	une	When this bit is set with Abnormal Interrupt Summary Enable (Bit 15), the Transmit Underflow Interrupt is enabled. When this bit is reset, the Underflow Interrupt is disabled. **Value** **Description** 0x0 Underflow Interrupt Disabled 0x1 Underflow Interrupt Enabled	RW	0x0
4	ove	When this bit is set with Abnormal Interrupt Summary Enable (Bit 15), the Receive Overflow Interrupt is enabled. When this bit is reset, the Overflow Interrupt is disabled. **Value** **Description** 0x0 Transmit Overflow Interrupt Disabled 0x1 Transmit Overflow Interrupt Enabled	RW	0x0

Bit	Name	Description	Access	Reset
3	tje	When this bit is set with Abnormal Interrupt Summary Enable (Bit 15), the Transmit Jabber Timeout Interrupt is enabled. When this bit is reset, the Transmit Jabber Timeout Interrupt is disabled. **Value** **Description** 0x0 Transmit Jabber Timeout Interrupt Disabled 0x1 Transmit Jabber Timeout Interrupt Enabled	RW	0x0
2	tue	When this bit is set with Normal Interrupt Summary Enable (Bit 16), the Transmit Buffer Unavailable Interrupt is enabled. When this bit is reset, the Transmit Buffer Unavailable Interrupt is disabled. **Value** **Description** 0x0 Transmit Buffer Unavailable Interrupt Disabled 0x1 Transmit Buffer Unavailable Interrupt Enabled	RW	0x0
1	tse	When this bit is set with Abnormal Interrupt Summary Enable (Bit 15), the Transmission Stopped Interrupt is enabled. When this bit is reset, the Transmission Stopped Interrupt is disabled. **Value** **Description** 0x0 Transmit Stopped Interrupt Disabled 0x1 Transmit Stopped Interrupt Enabled	RW	0x0
0	tie	When this bit is set with Normal Interrupt Summary Enable (Bit 16), the Transmit Interrupt is enabled. When this bit is reset, the Transmit Interrupt is disabled. **Value** **Description** 0x0 Transmit Interrupt Disabled 0x1 Transmit Interrupt Enabled	RW	0x0

Missed_Frame_And_Buffer_Overflow_Counter

The DMA maintains two counters to track the number of frames missed during reception. This register reports the current value of the counter. The counter is used for diagnostic purposes. Bits[15:0] indicate missed frames because of the host buffer being unavailable. Bits[27:17] indicate missed frames because of buffer overflow conditions (MTL and MAC) and runt frames (good frames of less than 64 bytes) dropped by the MTL.

Module Instance	Base Address	Register Address

Receive_Interrupt_Watchdog_Timer Fields

Bit	Name	Description	Access	Reset
7:0	riwt	This bit indicates the number of system clock cycles multiplied by 256 for which the watchdog timer is set. The watchdog timer gets triggered with the programmed value after the Rx DMA completes the transfer of a frame for which the RI status bit is not set because of the setting in the corresponding descriptor RDES1[31]. When the watchdog timer runs out, the RI bit is set and the timer is stopped. The watchdog timer is reset when the RI bit is set high because of automatic setting of RI as per RDES1[31] of any received frame.	RW	0x0

AXI_Bus_Mode

The AXI Bus Mode Register controls the behavior of the AXI master. It is mainly used to control the burst splitting and the number of outstanding requests.

Module Instance	Base Address	Register Address

AXI_Bus_Mode Fields

Bit	Name	Description	Access	Reset
31	en_lpi	When set to 1, this bit enables the LPI mode supported by the AXI master and accepts the LPI request from the AXI System Clock controller. When set to 0, this bit disables the LPI mode and always denies the LPI request from the AXI System Clock controller. **Value** **Description** 0x0 Disable LPI Mode 0x1 Enable LPI Mode	RW	0x0
30	lpi_xit_frm	When set to 1, this bit enables the GMAC-AXI to come out of the LPI mode only when the Remote Wake Up Packet is received. When set to 0, this bit enables the GMAC-AXI to come out of LPI mode when any frame is received. This bit must be set to 0. **Value** **Description** 0x0 Do Not exit LPI Mode with Magic Packet 0x1 Exit LPI Mode with Magic Packet	RW	0x0
23:20	wr_osr_lmt	AXI Maximum Write OutStanding Request Limit	RW	0x1
19:16	rd_osr_lmt	This value limits the maximum outstanding request on the AXI read interface. Maximum outstanding requests = RD_OSR_LMT+1	RW	0x1
13	onekbbe	1 KB Boundary Crossing Enable for the GMAC-AXI Master When set, the GMAC-AXI Master performs burst transfers that do not cross 1 KB boundary. When reset, the GMAC-AXI Master performs burst transfers that do not cross 4 KB boundary. **Value** **Description** 0x0 4K boundary 0x1 1K boundary	RW	0x0

Bit	Name	Description	Access	Reset
12	axi_aal	This bit is read-only bit and reflects the Bit 25 (AAL) of Register 0 (Bus Mode Register). When this bit is set to 1, the GMAC-AXI performs address-aligned burst transfers on both read and write channels. **Value** **Description** 0x0 No Address-Alignment Bursts 0x1 Address-Alignmnet Bursts	RO	0x0
3	blen16	When this bit is set to 1 or UNDEFINED is set to 1, the GMAC-AXI is allowed to select a burst length of 16 on the AXI Master interface. **Value** **Description** 0x0 AXI No Fixed Busrts 0x1 AXI Fixed Burst BLEN = 16	RW	0x0
2	blen8	When this bit is set to 1, the GMAC-AXI is allowed to select a burst length of 8 on the AXI Master interface. Setting this bit has no effect when UNDEFINED is set to 1. **Value** **Description** 0x0 AXI No Fixed Busrts 0x1 AXI Fixed Burst BLEN = 8	RW	0x0
1	blen4	When this bit is set to 1, the GMAC-AXI is allowed to select a burst length of 4 on the AXI Master interface. Setting this bit has no effect when UNDEFINED is set to 1. **Value** **Description** 0x0 AXI No Fixed Busrts 0x1 AXI Fixed Burst BLEN = 4	RW	0x0

Bit	Name	Description	Access	Reset
0	undefined	This bit is read-only bit and indicates the complement (invert) value of Bit 16 (FB) in Register 0 (Bus Mode Register[16]). * When this bit is set to 1, the GMAC-AXI is allowed to perform any burst length equal to or below the maximum allowed burst length programmed in Bits[7:1]. * When this bit is set to 0, the GMAC-AXI is allowed to perform only fixed burst lengths as indicated by BLEN16, BLEN8, or BLEN4, or a burst length of 1. **Value** **Description** 0x0 Fixed Burst Lengths 4 to 32 0x1 Any Burst Length up to max	RO	0x1

AHB_or_AXI_Status

This register provides the active status of the AXI interface's read and write channels. This register is useful for debugging purposes.

Module Instance	Base Address	Register Address

Document Revision History

Table 17-24: Document Revision History

Date	Version	Changes
December 2014	2014.12.15	• Updated *EMAC Block Diagram and System Integration* section with new diagram and information. • Added *Signal Descriptions* section. • Added *EMAC Internal Interfaces* section. • Added *TX FIFO* and *RX FIFO* subsection to the *Transmit and Receive Data FIFO Buffers* section.

Date	Version	Changes
		• Updated *Descriptor Overview* section to clarify support for only enhanced (alternate) descriptors. • Added *Destination and Source Address Filtering Summary* in *Frame Filtering* Section. • Added *Clock Structure* sub-section to *Clocks and Resets* section • Added *System Level EMAC Configuration Registers* section in *Ethernet Programming Model* • Added *EMAC Interface Initialization for FPGA GMII/MII Mode* section in Ethernet Programming Model • Added *EMAC Interface Initialization for RGMII/RMII Mode* section in Ethernet Programming Model • Corrected *DMA Initialization* and *EMAC Initialization and Configuration* titles to appear on correct initialization information • Removed duplicate programming information for DMA • Added *Taking the Ethernet MAC Out of Reset* section.
June 2014	2014.06.30	Updated EMAC to RGMII Interface table with EMAC Port names Updated EMAC to FPGA PHY Interface table with Signal names Updated EMAC to FPGA IEEE1588 Timestamp Interface with Signal names Added Address Map and Register Descriptions
February 2014	2014.02.28	ECC updates.
December 2013	1.4	Maintenance release.

Date	Version	Changes
November 2012	1.3	• Expanded shared memory block table. • Added CSEL tables. • Additional minor updates.
June 2012	1.2	Updated the HPS boot and FPGA configuration sections.

USB 2.0 OTG Controller 18

2014.12.15

av_5v4 Subscribe Send Feedback

The hard processor system (HPS) provides two instances of a USB On-The-Go (OTG) controller that supports both device and host functions. The controller supports all high-speed, full-speed, and low-speed transfers in both device and host modes. The controller is fully compliant with the *On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification*. The controller can be programmed for both device and host functions to support data movement over the USB protocol.

The controllers are operationally independent of each other. Each USB OTG controller supports a single USB port connected through a USB 2.0 Transceiver Macrocell Interface Plus (UTMI+) Low Pin Interface (ULPI) compliant PHY. The USB OTG controllers are instances of the Synopsys® (†)DesignWare® Cores USB 2.0 Hi-Speed On-The-Go (DWC_otg) controller.

The USB OTG controller is optimized for the following applications and systems: †

- Portable electronic devices †
- Point-to-point applications (no hub, direct connection to HS, FS, or LS device) †
- Multi-point applications (as an embedded USB host) to devices (hub and split support) †

Each of the two USB OTG ports supports both host and device modes, as described in the *On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification*. The USB OTG ports support connections for all types of USB peripherals, including the following peripherals:

- Mouse
- Keyboard
- Digital cameras
- Network adapters
- Hard drives
- Generic hubs

Additional information is available in the On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification, which you can download from the USB Implementers Forum website

Features of the USB OTG Controller

The USB OTG controller has the following USB-specific features:

- Complies with both Revision 1.3 and Revision 2.0 of the *On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification*
- Supports software-configurable modes of operation between OTG 1.3 and OTG 2.0
- Supports all USB 2.0 speeds:
  - High speed (HS, 480-Mbps)
  - Full speed (FS, 12-Mbps)
  - Low speed (LS, 1.5-Mbps)

  Note: In host mode, all speeds are supported. However, in device mode, only high speed and full speed are supported.
- Supports USB 2.0 in ULPI mode
- Supports all USB transaction types:
  - Control transfers
  - Bulk transfers
  - Isochronous transfers
  - Interrupts
- Supports automatic ping capability
- Supports Session Request Protocol (SRP) and Host Negotiation Protocol (HNP)
- Supports suspend, resume, and remote wake
- Supports up to 16 host channels

  Note: In host mode, when the number of device endpoints is greater than the number of host channels, software can reprogram the channels to support up to 127 devices, each having 32 endpoints (IN + OUT), for a maximum of 4,064 endpoints.
- Supports up to 16 bidirectional endpoints, including control endpoint 0

  Note: Only seven periodic device IN endpoints are supported.
- Supports a generic root hub
- Performs transaction scheduling in hardware

On the USB PHY layer, the USB OTG controller supports the following features:

- A single USB port connected to each OTG instance
- A ULPI connection to an off-chip USB transceiver
- Software-controlled access, supporting vendor-specific or optional PHY registers access to ease debug
- The OTG 2.0 support for Attach Detection Protocol (ADP) only through an external (off-chip) ADP controller

On the integration side, the USB OTG controller supports the following features:

- Different clocks for system and PHY interfaces
- Dedicated TX FIFO buffer for each device IN endpoint in direct memory access (DMA) mode
- Packet-based, dynamic FIFO memory allocation for endpoints for small FIFO buffers and flexible, efficient use of RAM that can be dynamically sized by software
- Ability to change an endpoint's FIFO memory size during transfers
- Clock gating support during USB suspend and session-off modes
  - PHY clock gating support
  - System clock gating support
- Data FIFO RAM clock gating support
- Local buffering with error correction code (ECC) support

Note: The USB OTG controller does not support the following protocols:

- Enhanced Host Controller Interface (EHCI)
- Open Host Controller Interface (OHCI)
- Universal Host Controller Interface (UHCI)

Supported PHYS

The USB OTG controller only supports USB 2.0 ULPI PHYs. Only the single data rate (SDR) mode is supported.

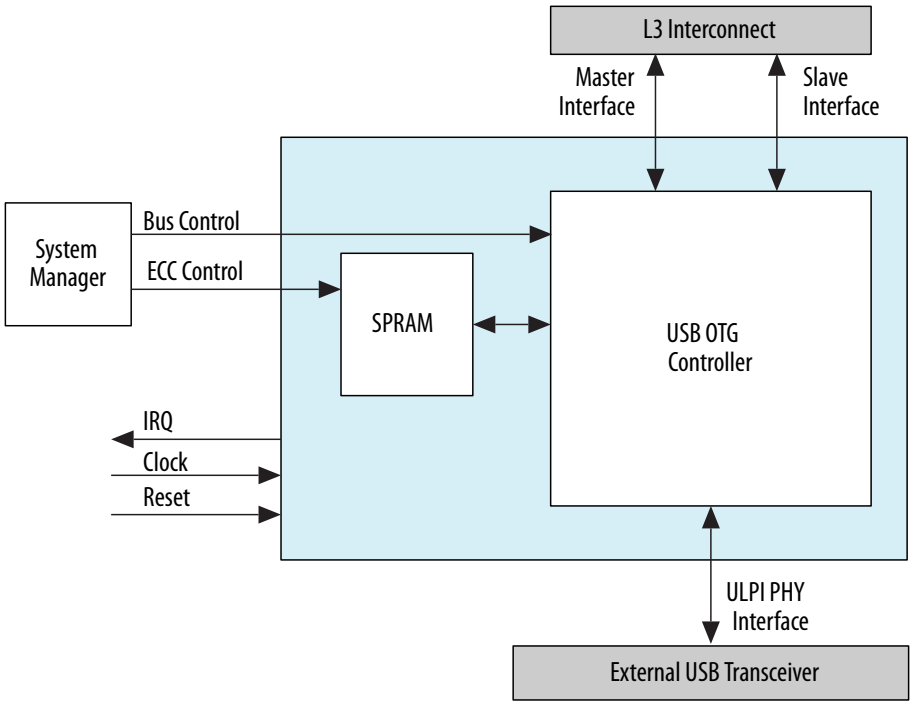
PHYs that support LPM mode may not function properly with the USB controller due to a timing issue. It is recommended that designers use the MicroChip USB3300 PHY device that has been proven to be successful on the development board.

Refer to the *Arria V Device Datasheet* for specific timing information.

USB OTG Controller Block Diagram and System Integration

Figure 18-1: USB OTG Controller System Integration

Two subsystems are included in the HPS.



The USB OTG controller connects to the level 3 (L3) interconnect through a slave interface, allowing other masters to access the control and status registers (CSRs) in the controller. The controller also connects to the L3 interconnect through a master interface, allowing the DMA engine in the controller to move data between external memory and the controller.

A single-port RAM (SPRAM) connected to the USB OTG controller is used to store USB data packets for both host and device modes. It is configured as FIFO buffers for receive and transmit data packets on the USB link.

Through the system manager, the USB OTG controller has control to use and test error correction codes (ECCs) in the SPRAM. Through the system manager, the USB OTG controller can also control the behavior of the master interface to the L3 interconnect.

The USB OTG controller connects to the external USB transceiver through a ULPI PHY interface. This interface also connects through pin multiplexers within the HPS. The pin multiplexers are controlled by the system manager.

Additional connections on the USB OTG controller include:

- Clock input from the clock manager to the USB OTG controller
- Reset input from the reset manager to the USB OTG controller
- Interrupt line from the USB OTG controller to the microprocessor unit (MPU) global interrupt controller (GIC).

The USB controller will only use Direct Shared IO 48.

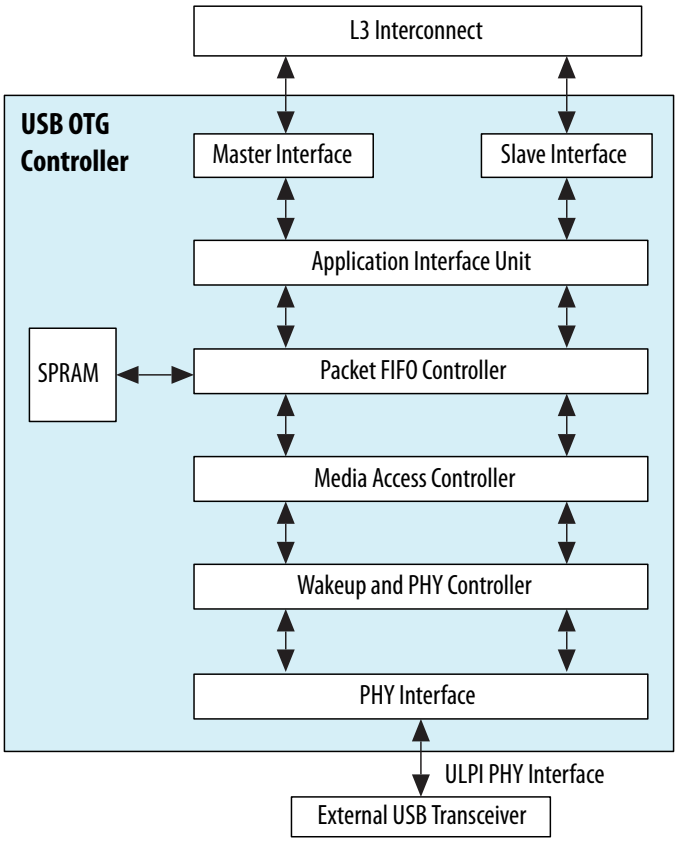
Functional Description of the USB OTG Controller

USB OTG Controller Block Description

Figure 18-2: USB OTG Controller Block Description

Details about each of the units that comprise the USB OTG controller are shown below.



Master Interface

The master interface includes a built-in DMA controller. The DMA controller moves data between external memory and the media access controller (MAC).

Properties of the master interface are controlled through the USB L3 Master HPROT Register (`l3master`) in the system manager. These bits provide access information to the L3 interconnect, including whether or not transactions are cacheable, bufferable, or privileged.

Note: Bits in the `l3master` register can be updated only when the master interface is guaranteed to be in an inactive state.

Slave Interface

The slave interface allows other masters in the system to access the USB OTG controller's CSRs. For testing purposes, other masters can also access the SPRAM.

Slave Interface CSR Unit

The slave interface can read from and write to all the CSRs in the USB OTG controllers. All register accesses are 32 bits.

The CSR is divided into the following groups of registers:

- Global
- Host
- Device
- Power and clock gating

Some registers are shared between host and device modes, because the controller can only be in one mode at a time. The controller generates a mode mismatch interrupt if a master attempts to access device registers when the controller is in host mode, or attempts to access host registers when the controller is in device mode. Writing to unimplemented registers is ignored. Reading from unimplemented registers returns indeterminate values.

Application Interface Unit

The application interface unit (AIU) generates DMA requests based on programmable FIFO buffer thresholds. The AIU generates interrupts to the GIC for both host and device modes. A DMA scheduler is included in the AIU to arbitrate and control the data transfer between packets in system memory and their respective USB endpoints.

Packet FIFO Controller

The Packet FIFO Controller (PFC) connects the AIU with the MAC through data FIFO buffers located in the SPRAM. In device mode, one FIFO buffer is implemented for each IN endpoint. In host mode, a single FIFO buffer stores data for all periodic (isochronous and interrupt) OUT endpoints, and a single FIFO buffer is used for nonperiodic (control and bulk) OUT endpoints. Host and device mode share a single receive data FIFO buffer.

SPRAM

An SPRAM implements the data FIFO buffers for host and device modes. The size of the FIFO buffers can be programmed dynamically.

The SPRAM supports ECCs. ECCs can be enabled through the system manager, by setting the RAM ECC Enable (`en`) bit in the USB0 or USB1 RAM ECC Enable Register (`usb0` or `usb1`), in the ECC Management Register Group (`eccgrp`). Single-bit and double-bit errors in each USB instance can be injected using this register.

The SPRAM provides outputs to notify the system manager when single-bit correctable errors are detected (and corrected), and when double-bit (uncorrectable) errors are detected. The system manager generates an interrupt to the GIC when an ECC error is detected.

MAC

The MAC module implements the following functionality:

- USB transaction support
- Host protocol support
- Device protocol support
- OTG protocol support
- Link power management (LPM) functions

USB Transactions

In device mode, the MAC decodes and checks the integrity of all token packets. For valid OUT or SETUP tokens, the following DATA packet is also checked. If the data packet is valid, the MAC performs the following steps:

1. Writes the data to the receive FIFO buffer
2. Sends the appropriate handshake when required to the USB host

If a receive FIFO buffer is not available, the MAC sends a NAK response to the host. The MAC also supports ping protocol.

For IN tokens, if data is available in the transmit FIFO buffer, the MAC performs the following steps:

1. Reads the data from the FIFO buffer
2. Forms the data packet
3. Transmits the packet to the host
4. Receives the response from the host
5. Sends the updated status to the PFC

In host mode, the MAC receives a token request from the AIU. The MAC performs the following steps:

1. Builds the token packet
2. Sends the packet to the device

For OUT or SETUP transactions, the MAC also performs the following steps:

1. Reads the data from the transmit FIFO buffer
2. Assembles the data packet
3. Sends the packet to the device
4. Waits for a response

The response from the device causes the MAC to send a status update to the AIU.

For IN or PING transactions, the MAC waits for the data or handshake response from the device. For data responses, the MAC performs the following steps:

1. Validates the data
2. Writes the data to the receive FIFO buffer
3. Sends a status update to the AIU
4. Sends a handshake to the device, if appropriate

Host Protocol

In host mode, the MAC performs the following functions:

- Detects connect, disconnect, and remote wakeup events on the USB link
- Initiates reset
- Initiates speed enumeration processes
- Generates Start of Frame (SOF) packets.

Device Protocol

In device mode, the MAC performs the following functions:

- Handles USB reset sequence
- Handles speed enumeration
- Detects USB suspend and resume activity on the USB link
- Initiates remote wakeup
- Decodes SOF packets

OTG Protocol

The MAC handles HNP and SRP for OTG operation. HNP provides a mechanism for swapping host and device roles. SRP provides mechanisms for the host to turn off V_{BUS} to save power, and for a device to request a new USB session.

LPM Functions

The USB OTG controller supports LPM in both host and device modes. With this feature, the USB OTG controller can enter a sleep state when a successful LPM transaction occurs on the USB link.

Wakeup and Power Control

To reduce power, the USB OTG controller supports a power-down mode. In power-down mode, the controller and the PHY can shut down their clocks. The controller supports wakeup on the detection of the following events:

- Resume
- Remote wakeup
- Session request protocol
- New session start

PHY Interface Unit

The USB OTG controller supports synchronous SDR data transmission to a ULPI PHY. The SDR mode implements an eight-bit data bus.

ULPI PHY Interface

Table 18-1: ULPI PHY Interfaces

The ULPI PHY interface is synchronous to the `ulpi_clk` signal coming from the PHY.

Port Name	Bit Width	Direction	Description
`ulpi_clk`	1	Input	ULPI Clock Receives the 60-MHz clock supplied by the high-speed ULPI PHY. All signals are synchronous to the positive edge of the clock.
`ulpi_dir`	1	Input	ULPI Data Bus Control 1—The PHY has data to transfer to the USB OTG controller. 0—The PHY does not have data to transfer.
`ulpi_nxt`	1	Input	ULPI Next Data Control Indicates that the PHY has accepted the current byte from the USB OTG controller. When the PHY is transmitting, this signal indicates that a new byte is available for the controller.
`ulpi_stp`	1	Output	ULPI Stop Data Control The controller drives this signal high to indicate the end of its data stream. The controller can also drive this signal high to request data from the PHY.
`ulpi_data[7:0]`	8	Bidirectional	Bidirectional data bus. Driven low by the controller during idle.

Local Memory Buffer

The NAND flash controller has three local SRAM memory buffers.

- The write FIFO buffer is a 128 × 32-bit memory (512 total bytes)
- The read FIFO buffer is a 32 × 32-bit memory (128 total bytes)
- The ECC buffer is a 96 × 16-bit memory (1536 total bytes)

The SPRAM is a 8192 x 35-bit (32 data bits and 3 control bits) memory and includes support for ECC (Error Checking and Correction). The ECC block is integrated around a memory wrapper. It provides outputs to notify the system manager when single-bit correctable errors are detected (and corrected) and when double-bit uncorrectable errors are detected. The ECC logic also allows the injection of single- and double-bit errors for test purposes. The ECC feature is disabled by default. It must be initialized to enable the ECC function.

Clocks

Table 18-2: USB OTG Controller Clock Inputs

All clocks must be operational when reset is released. No special handling is required on the clocks.

Clock Signal	Frequency	Functional Usage
usb_mp_clk	60 – 200 MHz	Drives the master and slave interfaces, DMA controller, and internal FIFO buffers
usb0_ulpi_clk	60 MHz	ULPI reference clock for usb0 from external ULPI PHY I/O pin
usb1_ulpi_clk	60 MHz	ULPI reference clock for usb1 from external ULPI PHY I/O pin

Resets

The USB OTG controller can be reset either through the hardware reset input or through software.

Reset Requirements

There must be a minimum of 12 cycles on the ulpi_clk clock before the controller is taken out of reset. During reset, the USB OTG controller asserts the ulpi_stp signal. The PHY outputs a clock when it sees the ulpi_stp signal asserted. However, if the pin multiplexers are not programmed, the PHY does not see the ulpi_stp signal. As a result, the ulpi_clk clock signal does not arrive at the USB OTG controller.

Software must ensure that the reset is active for a minimum of two usb_mp_c lk cycles. There is no maximum assertion time.

Hardware Reset

Each of the USB OTG controllers has one reset input from the reset manager. The reset signal is asserted during a cold or warm reset event. The reset manager holds the controllers in reset until software releases the resets. Software releases resets by clearing the appropriate USB bits in the Peripheral Module Reset Register (permodrst) in the HPS reset manager.

The reset input resets the following blocks:

- The master and slave interface logic
- The integrated DMA controller
- The internal FIFO buffers
- The CSR

The reset input is synchronized to the usb_mp_clk domain. The reset input is also synchronized to the ULPI clock within the USB OTG controller and is used to reset the ULPI PHY domain logic.

Software Reset

Software can reset the controller by setting the Core Soft Reset (csftrst) bit in the Reset Register (grstctl) in the Global Registers (globgrp) group of the USB OTG controller.

Software resets are useful in the following situations:

- A PHY selection bit is changed by software. Resetting the USB OTG controller is part of clean-up to ensure that the PHY can operate with the new configuration or clock.
- During software development and debugging.

Taking the USB 2.0 OTG Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the MPU boots up, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

Interrupts

Table 18-3: USB OTG Interrupt Conditions

Each USB OTG controller has a single interrupt output. Interrupts are asserted on the conditions shown in the following table.

Condition	Mode
Device-initiated remote wakeup is detected.	Host mode
Session request is detected from the device.	Host mode
Device disconnect is detected.	Host mode
Host LPM entry retry has expired or LPM transaction(s) are complete.	Host mode
Host periodic TX FIFO buffer is empty (can be further programmed to indicate half-empty).	Host mode
Host channels interrupt received.	Host mode
Incomplete periodic transfer is pending at the end of the microframe.	Host mode
Host port status interrupt received.	Host mode
External host initiated resume is detected.	Device mode
LPM handshake is sent.	Device mode
Reset is detected when in suspend or normal mode.	Device mode
USB suspend mode is detected.	Device mode

Condition	Mode
Data fetch is suspended due to TX FIFO buffer full or request queue full.	Device mode
At least one isochronous OUT endpoint is pending at the end of the microframe.	Device mode
At least one isochronous IN endpoint is pending at the end of the microframe.	Device mode
At least one IN or OUT endpoint interrupt is pending at the end of the microframe.	Device mode
The end of the periodic frame is reached.	Device mode
Failure to write an isochronous OUT packet to the RX FIFO buffer. The RX FIFO buffer does not have enough space to accommodate the maximum packet size for the isochronous OUT endpoint.	Device mode
Enumeration has completed.	Device mode
Connector ID change.	Common modes
Mode mismatch. Software accesses registers belonging to an incorrect mode.	Common modes
Nonperiodic TX FIFO buffer is empty.	Common modes
RX FIFO buffer is not empty.	Common modes
Start of microframe.	Common modes
Device connection debounce is complete in host mode.	OTG interrupts
A-Device timeout while waiting for B-Device connection.	OTG interrupts
Host negotiation is complete.	OTG interrupts
Session request is complete.	OTG interrupts
Session end is detected in device mode.	OTG interrupts

USB OTG Controller Programming Model

For detailed information about using the USB OTG controller, consult your operating system (OS) driver documentation. The OS vendor provides application programming interfaces (APIs) to control USB host, device and OTG operation. This section provides a brief overview of the following software operations:

- Enabling SPRAM ECCs
- Host operation
- Device operation

Enabling SPRAM ECCs

To avoid false ECC errors, you must initialize the ECC bits in the SPRAM before using ECCs. To initialize the ECC bits, software writes data to all locations in the SPRAM.

The L3 interconnect has access to the SPRAM and is accessible through the USB OTG L3 slave interface. Software accesses the SPRAM through the `directfifo` memory space, in the USB OTG controller address space.

The SPRAM contains 8192 (32 KB) locations. The L3 slave provides 32-bit access to the SPRAM. Physically, the SPRAM is implemented as a 35-bit memory, with the highest three bits reserved for the USB OTG controller's internal use. When a write is performed to the SPRAM through the L3 slave interface, bits 32 through 34 of the internal data bus are tied to 1, to enable the ECC bits to be initialized.

Note: Software cannot access the SPRAM beyond the 32-KB range. Out-of-range read transactions return indeterminate data. Out-of-range write transactions are ignored.

Host Operation

Host Initialization

After power up, the USB port is in its default mode. No VBUS is applied to the USB cable. The following process sets up the USB OTG controller as a USB host.

1. To enable power to the USB port, the software driver sets the Port Power (`prtpwr`) bit to 1 in the Host Port Control and Status Register (`hprt`) of the Host Mode Registers (`hostgrp`) group. This action drives the V_{BUS} signal on the USB link.

   The controller waits for a connection to be detected on the USB link.
2. When a USB device connects, an interrupt is generated. The Port Connect Detected (`PrtConnDe t`) bit in `hprt` is set to 1.
3. Upon detecting a port connection, the software driver initiates a port reset by setting the Port Reset (`prtrst`) bit to 1 in `hprt`.
4. The software driver must wait a minimum of 10 ms so that speed enumeration can complete on the USB link.
5. After the 10 ms, the software driver sets `prtrst` back to 0 to release the port reset.
6. The USB OTG controller generates an interrupt. The Port Enable Disable Change (`prtenchng`) and Port Speed (`prtspd`) bits, in `hprt`, are set to reflect the enumerated speed of the device that attached.

   At this point the port is enabled for communication. Keep alive or SOF packets are sent on the port. If a USB 2.0-capable device fails to initialize correctly, it is reported as a USB 1.1 device.

The Host Frame Interval Register (hfir) is updated with the corresponding PHY clock settings. The hfir, used for sending SOF packets, is in the Host Mode Registers (host grp) group.

7. The software driver must program the following registers in the Global Registers (globgrp) group, in the order listed:
   a. Receive FIFO Size Register (grxfsiz)—selects the size of the receive FIFO buffer
   b. Non-periodic Transmit FIFO Size Register (gnptxfsiz)—selects the size and the start address of the non-periodic transmit FIFO buffer for nonperiodic transactions
   c. Host Periodic Transmit FIFO Size Register (hptxfsiz)—selects the size and start address of the periodic transmit FIFO buffer for periodic transactions
8. System software initializes and enables at least one channel to communicate with the USB device.

Host Transaction

When configured as a host, the USB OTG controller pipes the USB transactions through one of two request queues (one for periodic transactions and one for nonperiodic transactions). Each entry in the request queue holds the SETUP, IN, or OUT channel number along with other information required to perform a transaction on the USB link. The sequence in which the requests are written to the queue determines the sequence of transactions on the USB link.

The host processes the requests in the following order at the beginning of each frame or microframe:

1. Periodic request queue, including isochronous and interrupt transactions
2. Nonperiodic request queue (bulk or control transfers)

The host schedules transactions for each enabled channel in round-robin fashion. When the host controller completes the transfer for a channel, the controller updates the DMA descriptor status in the system memory.

For OUT transactions, the host controller uses two transmit FIFO buffers to hold the packet payload to be transmitted. One transmit FIFO buffer is used for all nonperiodic OUT transactions and the other is used for all periodic OUT transactions.

For IN transactions, the USB host controller uses one receive FIFO buffer for all periodic and nonperiodic transactions. The controller holds the packet payload from the USB device in the receive FIFO buffer until the packet is transferred to the system memory. The receive FIFO buffer also holds the status of each packet received. The status entry holds the IN channel number along with other information, including received byte count and validity status.

For generic hub operations, the USB OTG controller uses SPLIT transfers to communicate with slower-speed devices downstream of the hub. For these transfers, the transaction accumulation or buffering is performed in the generic hub, and is scheduled accordingly. The USB OTG controller ensures that enough transmit and receive buffers are allocated when the downstream transactions are completed or when accumulated data is ready to be sent upstream.

Device Operation

Device Initialization

The following process sets up the USB OTG controller as a USB device:

1. After power up, the USB OTG controller must be set to the desired device speed by writing to the Device Speed (devspd) bits in the Device Configuration Register (dcfg) in the Device Mode Registers

(devgrp) group. After the device speed is set, the controller waits for a USB host to detect the USB port as a device port.

2. When an external host detects the USB port, the host performs a port reset, which generates an interrupt to the USB device software. The USB Reset (usbrst) bit in the Interrupt (port reset) register in the Global Registers (globgrp) group is set. The device software then sets up the data FIFO buffer to receive a SETUP packet from the external host. Endpoint 0 is not enabled yet.
3. After completion of the port reset, the operation speed required by the external host is known. Software reads the device speed status and sets up all the remaining required transaction fields to enable control endpoint 0.

After completion of this process, the device is receiving SOF packets, and is ready for the USB host to set up the device's control endpoint.

Device Transaction

When configured as a device, the USB OTG controller uses a single FIFO buffer to receive the data for all the OUT endpoints. The receive FIFO buffer holds the status of the received data packet, including the byte count, the data packet ID (PID), and the validity of the received data. The DMA controller reads the data out of the FIFO buffer as the data are received. If a FIFO buffer overflow condition occurs, the controller responds to the OUT packet with a NAK, and internally rewinds the pointers.

For IN endpoints, the controller uses dedicated transmit buffers for each endpoint. The application does not need to predict the order in which the USB host will access the nonperiodic endpoints. If a FIFO buffer underrun condition occurs during transmit, the controller inverts the cyclic redundancy code (CRC) to mark the packet as corrupt on the USB link.

The application handles one data packet at a time per endpoint in transaction-level operations. The software receives an interrupt on completion of every packet. Based on the handshake response received on the USB link, the application determines whether to retry the transaction or proceed with the next transaction, until all packets in the transfer are completed.

IN Transactions

For an IN transaction, the application performs the following steps:

1. Enables the endpoint
2. Triggers the DMA engine to write the associated data packet to the corresponding transmit FIFO buffer
3. Waits for the packet completion interrupt from the controller

When an IN token is received on an endpoint when the associated transmit FIFO buffer does not contain sufficient data, the controller performs the following steps:

1. Generates an interrupt
2. Returns a NAK handshake to the USB host

If sufficient data is available, the controller transmits the data to the USB host.

OUT Transactions

For an OUT transaction, the application performs the following steps:

1. Enables the endpoint
2. Waits for the packet received interrupt from the USB OTG controller
3. Retrieves the packet from the receive FIFO buffer

When an OUT token or PING token is received on an endpoint where the receive FIFO buffer does not have sufficient space, the controller performs the following steps:

1. Generates an interrupt
2. Returns a NAK handshake to USB host

If sufficient space is available, the controller stores the data in the receive FIFO buffer and returns an ACK handshake to the USB link.

Control Transfers

For control transfers, the application performs the following steps:

1. Waits for the packet received interrupt from the controller
2. Retrieves the packet from the receive buffer

Because the control transfer is governed by USB protocol, the controller always responds with an ACK handshake.

USB OTG Controller Address Map and Register Definitions

The address map and register definitions for the USB OTG Controller consists of the following region:

USB OTG Controller Module Registers Address Map on page 18-16
Registers in the USB OTG Controller Module. Only the Core Global, Power and Clock Gating, Data FIFO Access, and Host Port registers can be accessedin both Host and Device modes. When the USB OTG Controller is operating in one mode, either Device or Host, the application must not access registers from the other mode. If an illegal access occurs, a Mode Mismatch interrupt is generated and reflected in the Core Interrupt register (GINTSTS.ModeMis). When the core switches from one mode to another, the registers in the new mode must be reprogrammed as they would be after a power-on reset. The register address map is fixed and does not depend on the module configuration (for example, how many endpoints are implemented). Host and Device mode registers occupy different addresses.
