Logic Array Blocks and Adaptive Logic Modules in Arria V Devices

1

Subscribe Send Feedback

This chapter describes the features of the logic array block (LAB) in the Arria® V core fabric.

The LAB is composed of basic building blocks known as adaptive logic modules (ALMs) that you can configure to implement logic functions, arithmetic functions, and register functions.

You can use a quarter of the available LABs in the Arria V devices as a memory LAB (MLAB).

The Quartus® II software and other supported third-party synthesis tools, in conjunction with parameterized functions such as the library of parameterized modules (LPM), automatically choose the appropriate mode for common functions such as counters, adders, subtractors, and arithmetic functions.

This chapter contains the following sections:

- LAB
- ALM Operating Modes

Related Information

Arria V Device Handbook: Known Issues
Lists the planned updates to the *Arria V Device Handbook* chapters.

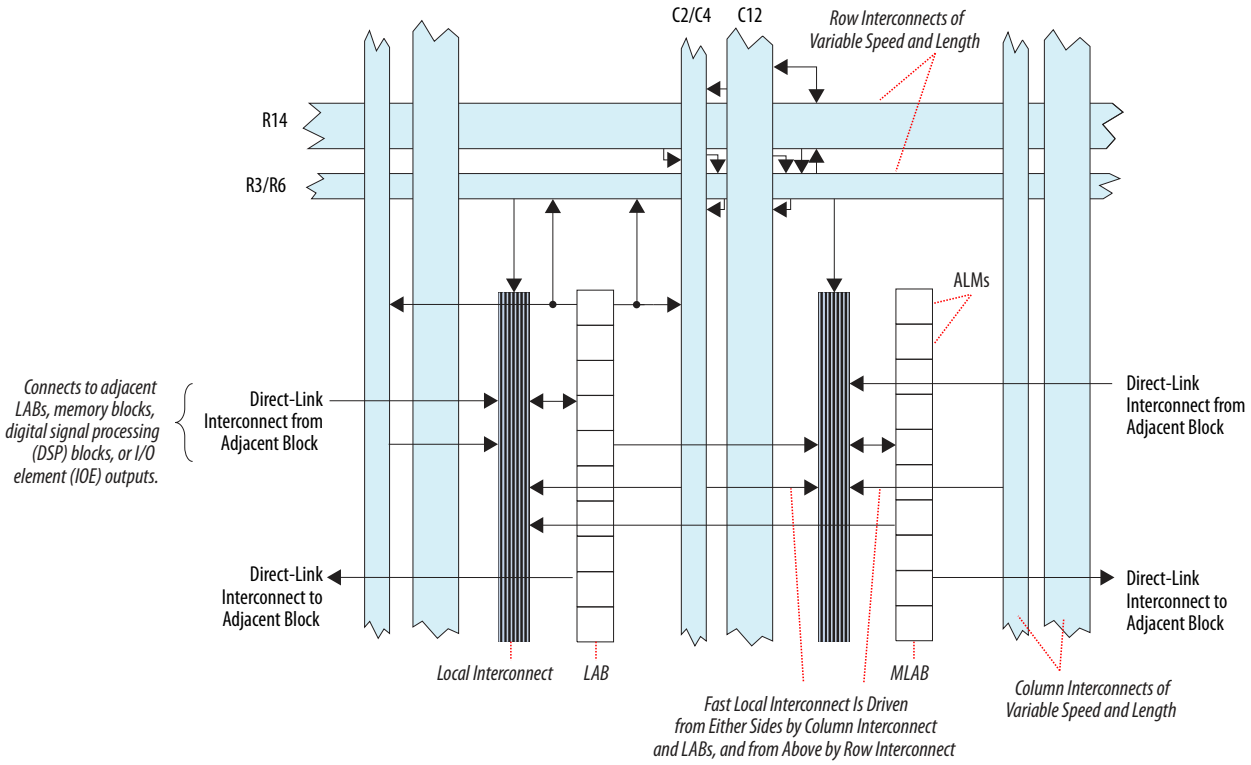
LAB

The LABs are configurable logic blocks that consist of a group of logic resources. Each LAB contains dedicated logic for driving control signals to its ALMs.

MLAB is a superset of the LAB and includes all the LAB features.

Figure 1-1: LAB Structure and Interconnects Overview in Arria V Devices

This figure shows an overview of the Arria V LAB and MLAB structure with the LAB interconnects.



MLAB

Each MLAB supports a maximum of 640 bits of simple dual-port SRAM.

You can configure each ALM in an MLAB in the following configurations:

- A 32 x 2 memory block, resulting in a configuration of 32 x 20 simple dual-port SRAM block for Arria V GX, GT, SX, and ST devices
- Either a 64 × 1 or a 32 × 2 block, resulting in a configuration of either a 64 × 10 or a 32 × 20 simple dual-port SRAM block for Arria V GZ devices

Figure 1-2: LAB and MLAB Structure for Arria V GX, GT, SX, and, ST Devices

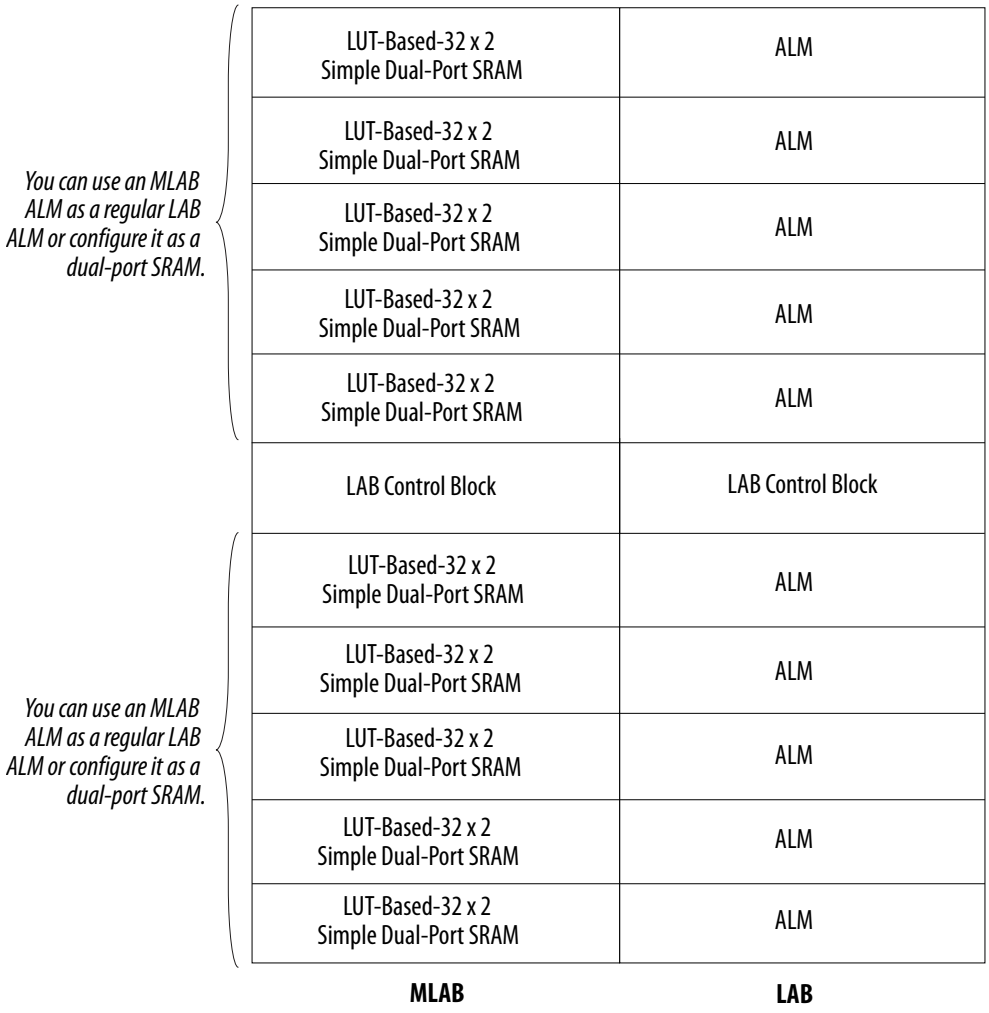


Figure 1-3: LAB and MLAB Structure for Arria V GZ Devices

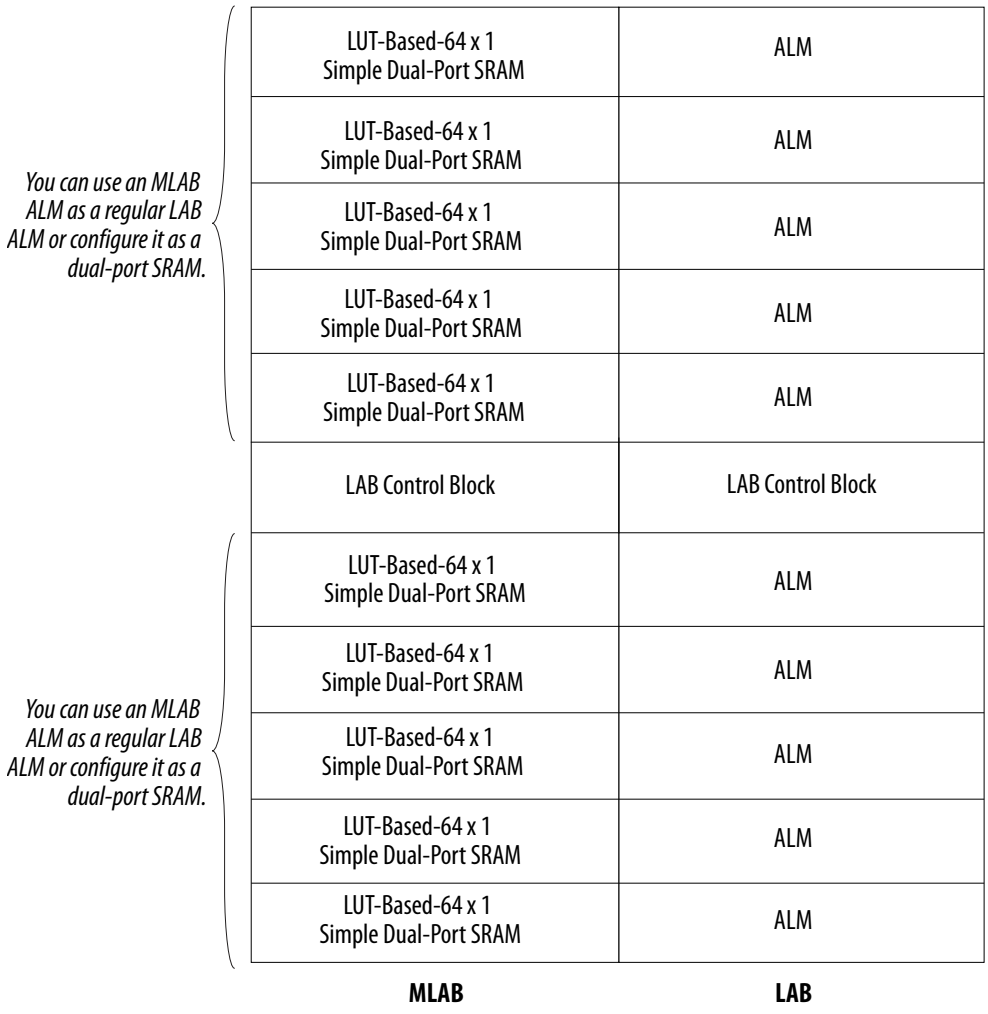


Local and Direct Link Interconnects

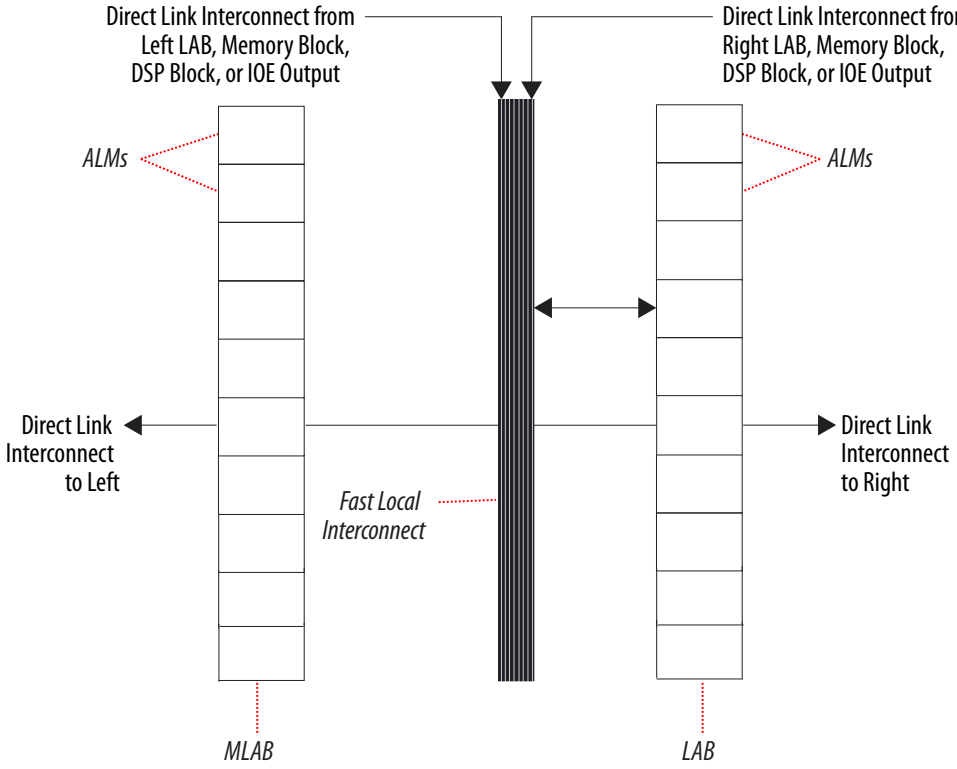
Each LAB can drive 30 ALMs through fast-local and direct-link interconnects. Ten ALMs are in any given LAB and ten ALMs are in each of the adjacent LABs.

The local interconnect can drive ALMs in the same LAB using column and row interconnects and ALM outputs in the same LAB.

Neighboring LABs, MLABs, M20K and M10K blocks, or digital signal processing (DSP) blocks from the left or right can also drive the LAB's local interconnect using the direct link connection.

The direct link connection feature minimizes the use of row and column interconnects, providing higher performance and flexibility.

Figure 1-4: LAB Fast Local and Direct Link Interconnects for Arria V Devices



LAB Control Signals

Each LAB contains dedicated logic for driving the control signals to its ALMs, and has two unique clock sources and three clock enable signals.

The LAB control block generates up to three clocks using the two clock sources and three clock enable signals. Each clock and the clock enable signals are linked.

De-asserting the clock enable signal turns off the corresponding LAB-wide clock.

Figure 1-5: LAB-Wide Control Signals for Arria V GX, GT, SX, and, ST Devices

This figure shows the clock sources and clock enable signals in a LAB.

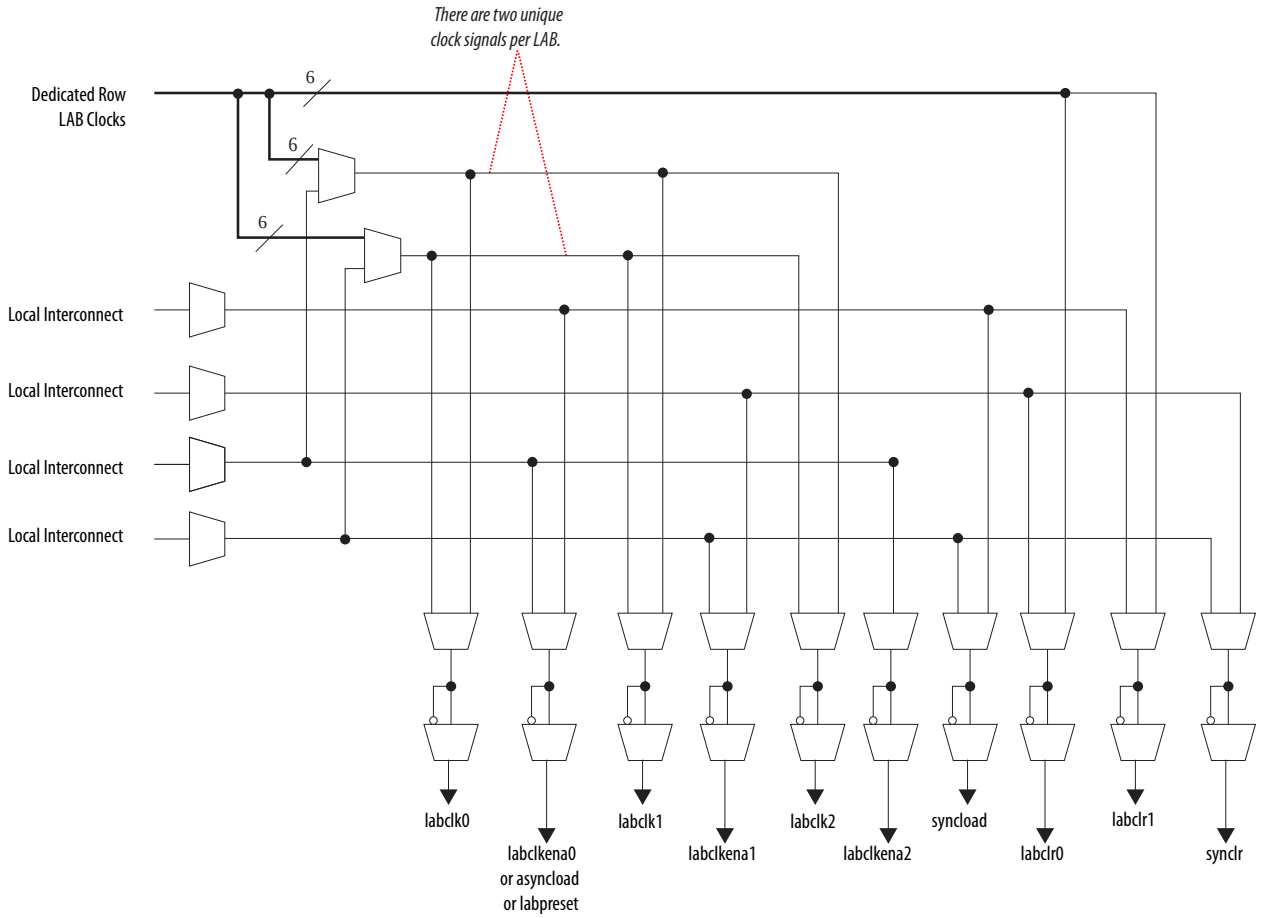


Figure 1-6: LAB-Wide Control Signals for Arria V GZ Devices

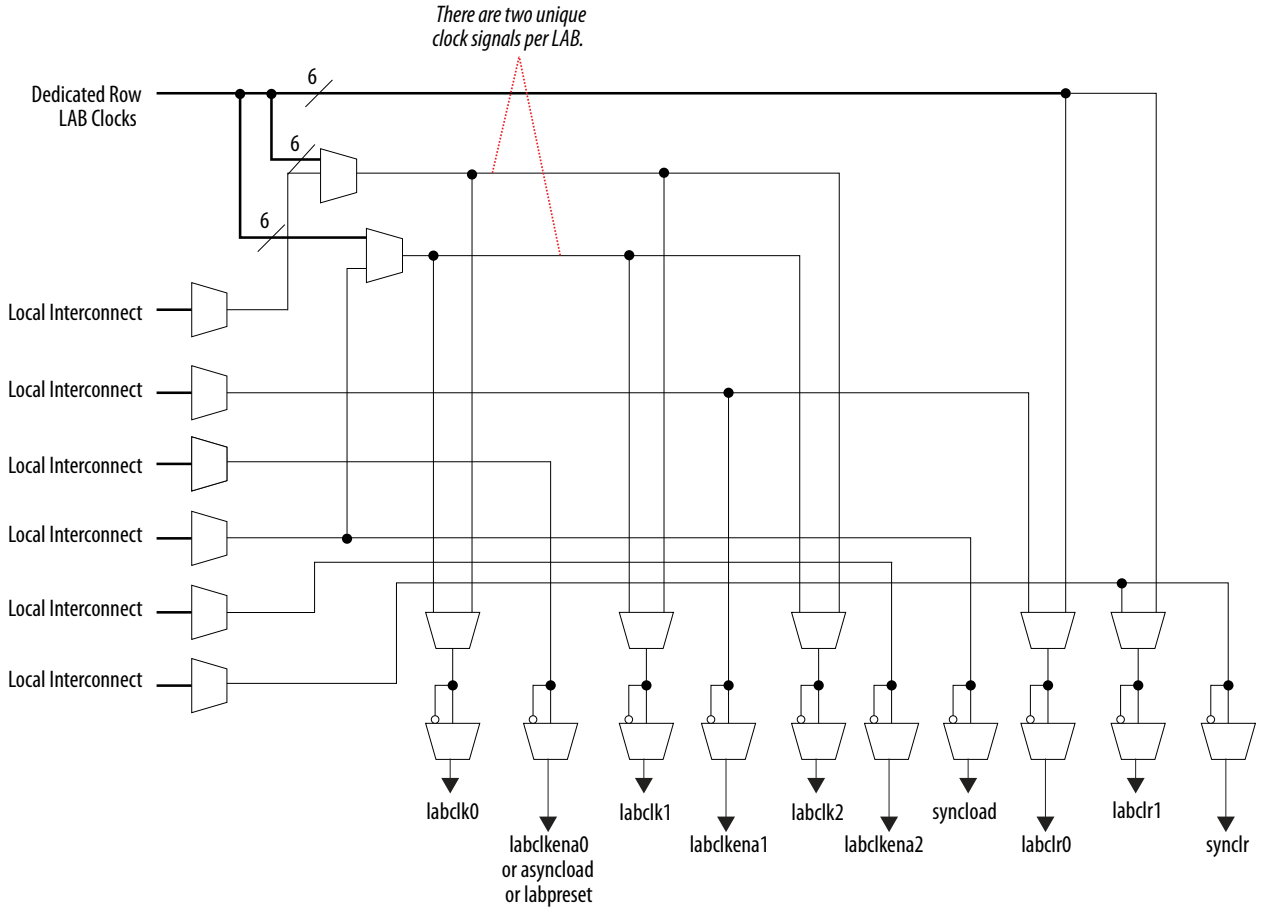
This figure shows the clock sources and clock enable signals in a LAB.



ALM Resources

One ALM contains four programmable registers. Each register has the following ports:

- Data
- Clock
- Synchronous and asynchronous clear
- Synchronous load

Global signals, general-purpose I/O (GPIO) pins, or any internal logic can drive the clock and clear control signals of an ALM register.

GPIO pins or internal logic drives the clock enable signal.

For combinational functions, the registers are bypassed and the output of the look-up table (LUT) drives directly to the outputs of an ALM.

Note: The Quartus II software automatically configures the ALMs for optimized performance.

Figure 1-7: ALM High-Level Block Diagram for Arria V GX, GT, SX, and, ST Devices

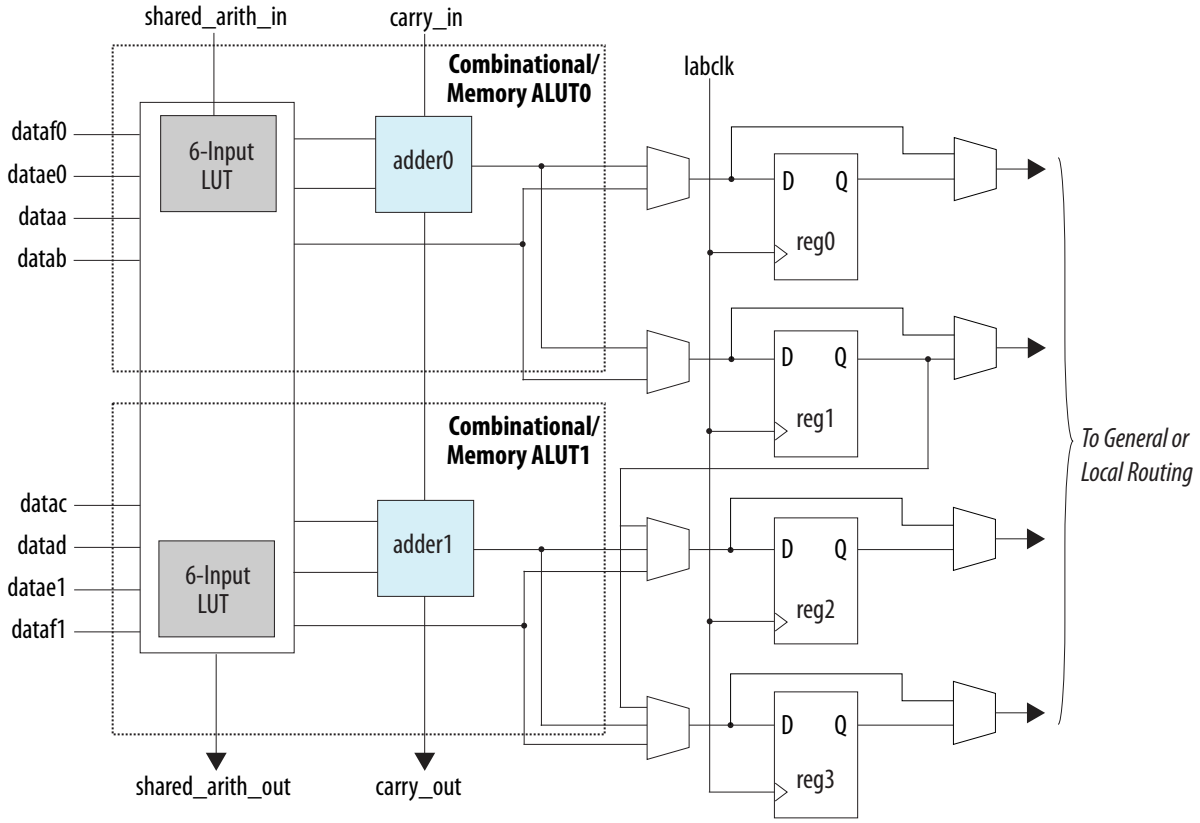


Figure 1-8: ALM High-Level Block Diagram for Arria V GZ Devices

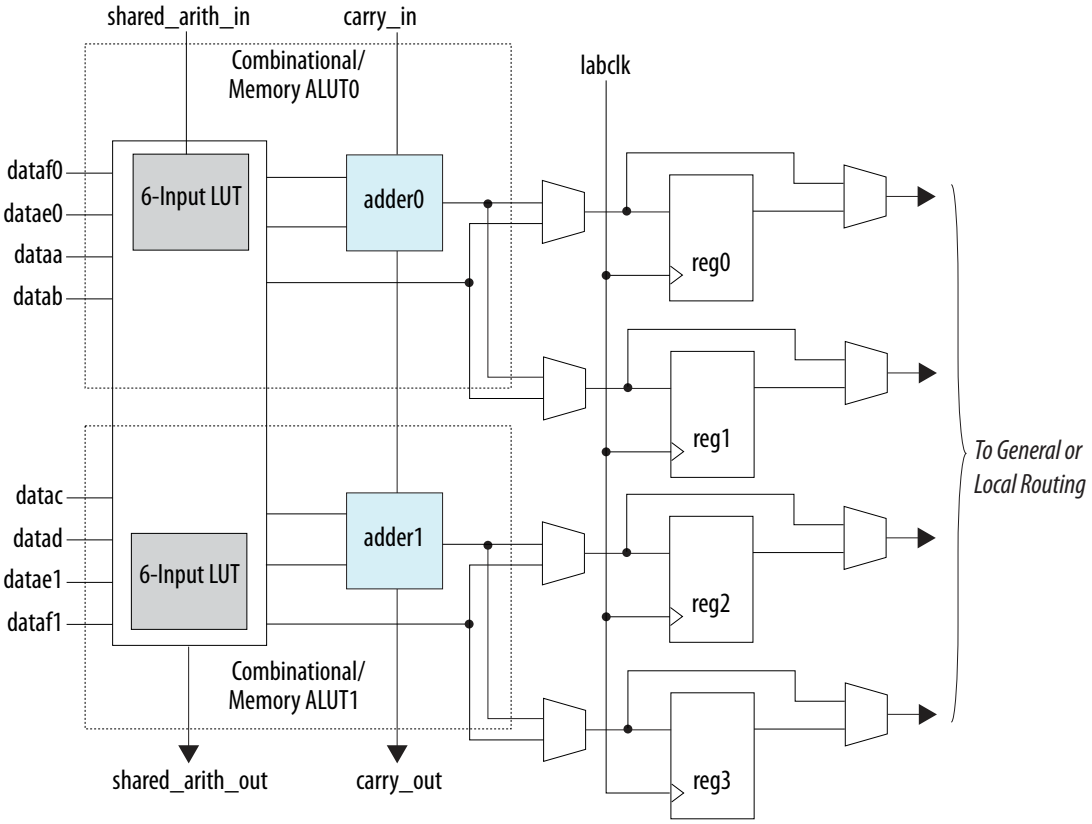

ALM Output

The general routing outputs in each ALM drive the local, row, and column routing resources. Two ALM outputs can drive column, row, or direct link routing connections, and one of these ALM outputs can also drive local interconnect resources.

The LUT, adder, or register output can drive the ALM outputs. The LUT or adder can drive one output while the register drives another output.

Register packing improves device utilization by allowing unrelated register and combinational logic to be packed into a single ALM. Another mechanism to improve fitting is to allow the register output to feed back into the look-up table (LUT) of the same ALM so that the register is packed with its own fan-out LUT. The ALM can also drive out registered and unregistered versions of the LUT or adder output.

Figure 1-9: ALM Connection Details for Arria V GX, GT, SX, and, ST Devices

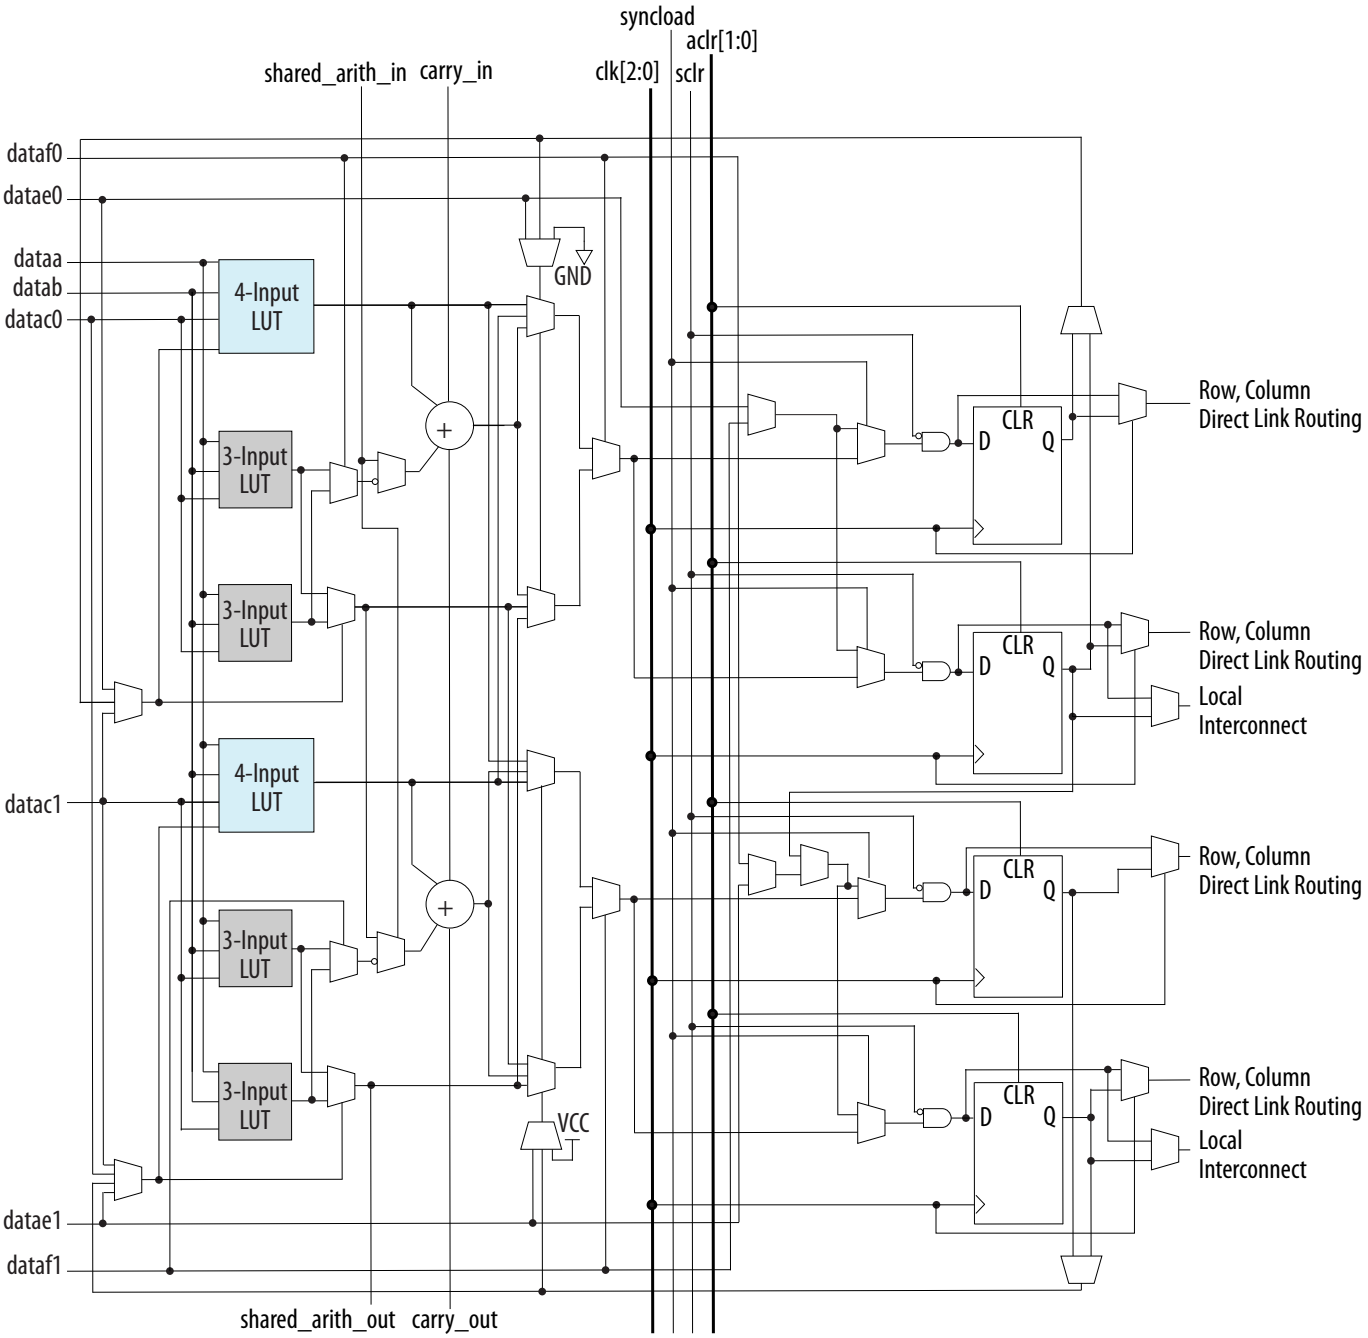

Figure 1-10: ALM Connection Details for Arria V GZ Devices

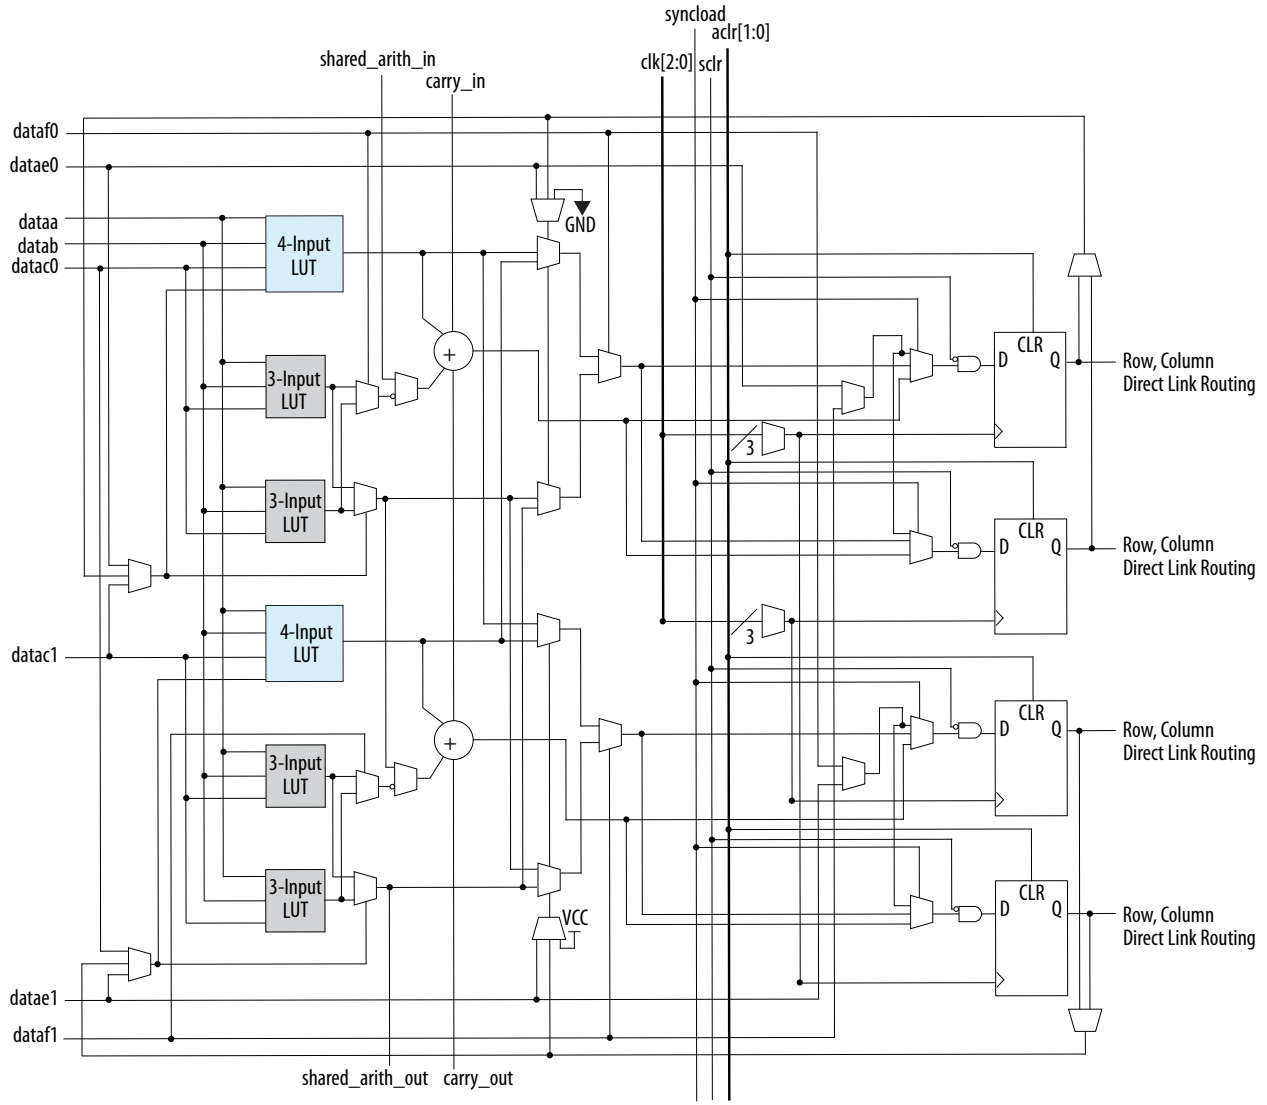


ALM Operating Modes

The Arria V ALM operates in any of the following modes:

- Normal mode
- Extended LUT mode
- Arithmetic mode
- Shared arithmetic mode

Normal Mode

Normal mode allows two functions to be implemented in one Arria V ALM, or a single function of up to six inputs.

Up to eight data inputs from the LAB local interconnect are inputs to the combinational logic.

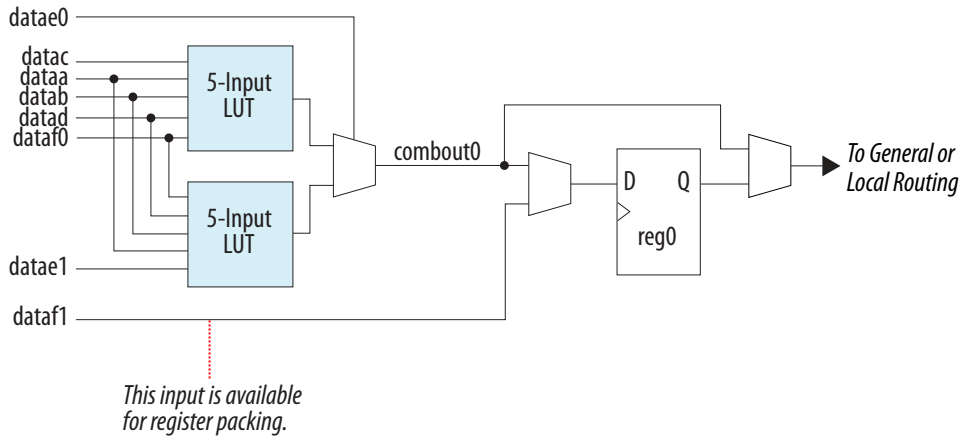
The ALM can support certain combinations of completely independent functions and various combinations of functions that have common inputs.

Extended LUT Mode

In this mode, if the 7-input function is unregistered, the unused eighth input is available for register packing.

Functions that fit into the template, as shown in the following figure, often appear in designs as "if-else" statements in Verilog HDL or VHDL code.

Figure 1-11: Template for Supported 7-Input Functions in Extended LUT Mode for Arria V Devices



Arithmetic Mode

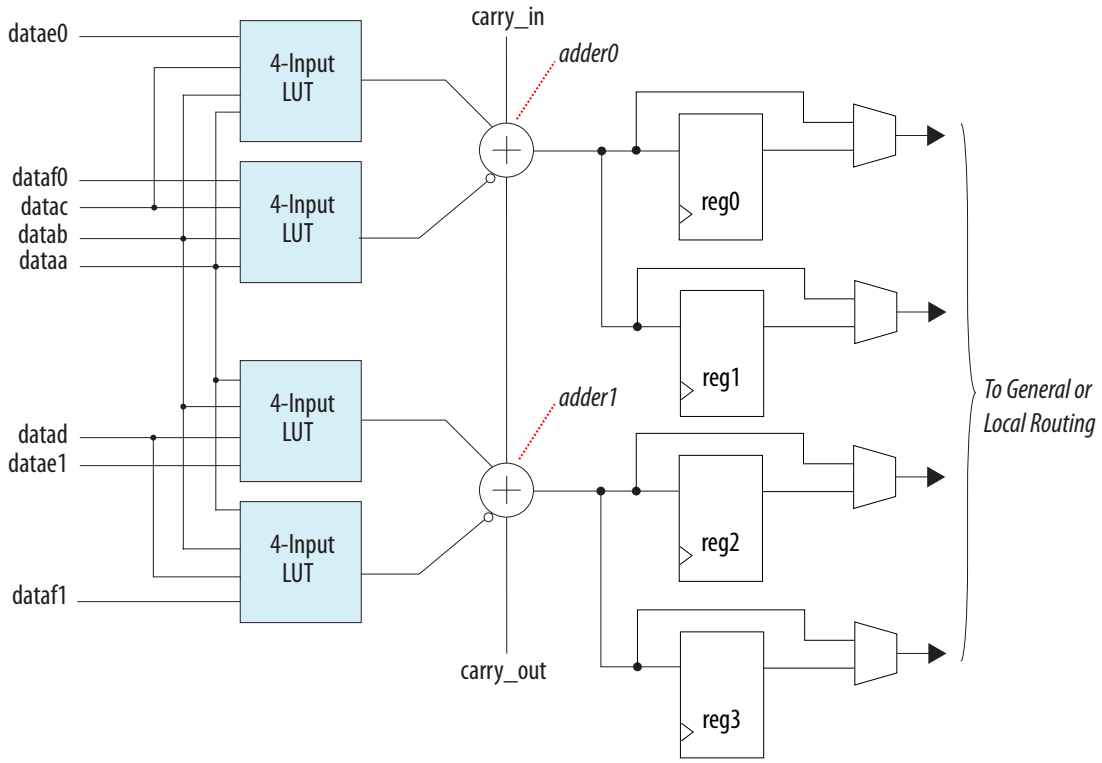
The ALM in arithmetic mode uses two sets of two 4-input LUTs along with two dedicated full adders.

The dedicated adders allow the LUTs to perform pre-adder logic; therefore, each adder can add the output of two 4-input functions.

The ALM supports simultaneous use of the adder's carry output along with combinational logic outputs. The adder output is ignored in this operation.

Using the adder with the combinational logic output provides resource savings of up to 50% for functions that can use this mode.

Figure 1-12: ALM in Arithmetic Mode for Arria V Devices



Carry Chain

The carry chain provides a fast carry function between the dedicated adders in arithmetic or shared arithmetic mode.

The two-bit carry select feature in Arria V devices halves the propagation delay of carry chains within the ALM. Carry chains can begin in either the first ALM or the fifth ALM in a LAB. The final carry-out signal is routed to an ALM, where it is fed to local, row, or column interconnects.

To avoid routing congestion in one small area of the device when a high fan-in arithmetic function is implemented, the LAB can support carry chains that only use either the top half or bottom half of the LAB before connecting to the next LAB. This leaves the other half of the ALMs in the LAB available for implementing narrower fan-in functions in normal mode. Carry chains that use the top five ALMs in the first LAB carry into the top half of the ALMs in the next LAB in the column. Carry chains that use the bottom five ALMs in the first LAB carry into the bottom half of the ALMs in the next LAB within the column. You can bypass the top-half of the LAB columns and bottom-half of the MLAB columns.

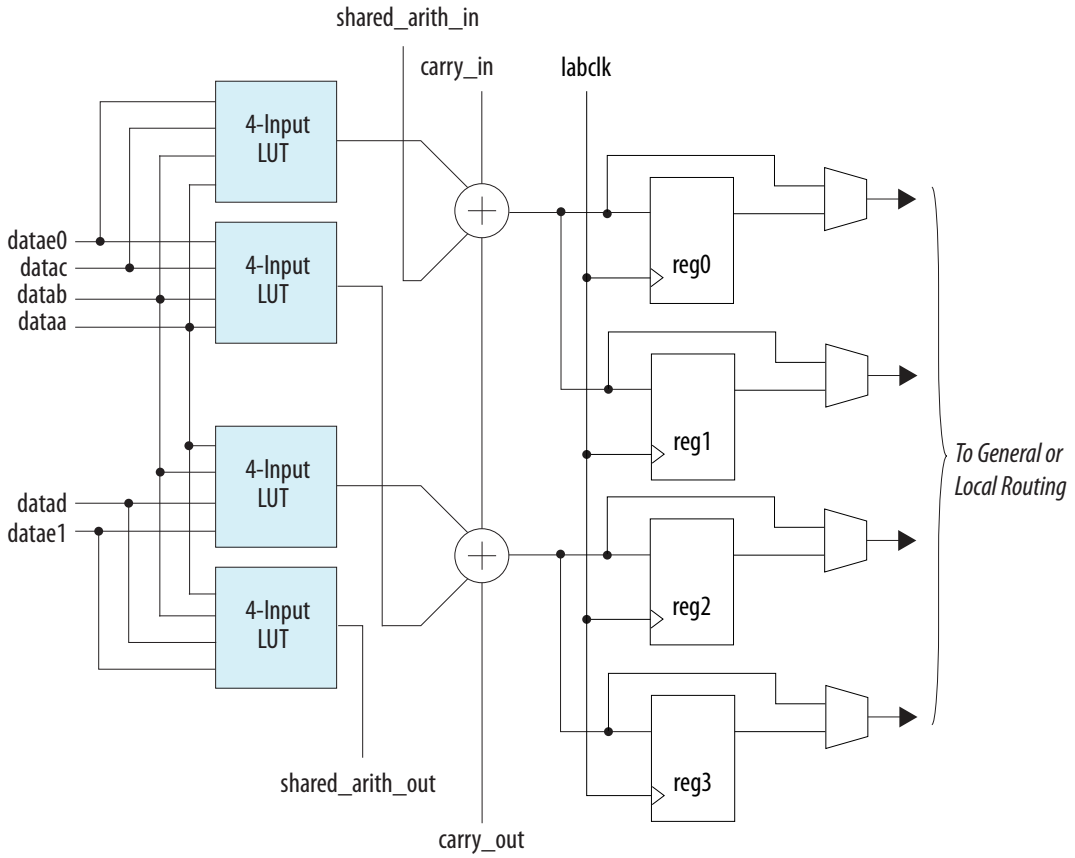
The Quartus II Compiler creates carry chains longer than 20 ALMs (10 ALMs in arithmetic or shared arithmetic mode) by linking LABs together automatically. For enhanced fitting, a long carry chain runs vertically, allowing fast horizontal connections to the TriMatrix memory and DSP blocks. A carry chain can continue as far as a full column.

Shared Arithmetic Mode

The ALM in shared arithmetic mode can implement a 3-input add in the ALM.

This mode configures the ALM with four 4-input LUTs. Each LUT either computes the sum of three inputs or the carry of three inputs. The output of the carry computation is fed to the next adder using a dedicated connection called the shared arithmetic chain.

Figure 1-13: ALM in Shared Arithmetic Mode for Arria V Devices



Shared Arithmetic Chain

The shared arithmetic chain available in enhanced arithmetic mode allows the ALM to implement a 3-input adder. This significantly reduces the resources necessary to implement large adder trees or correlator functions.

The shared arithmetic chain can begin in either the first or sixth ALM in a LAB.

Similar to carry chains, the top and bottom half of the shared arithmetic chains in alternate LAB columns can be bypassed. This capability allows the shared arithmetic chain to cascade through half of the ALMs in an LAB while leaving the other half available for narrower fan-in functionality. In every LAB, the column is top-half bypassable; while in MLAB, columns are bottom-half bypassable.

The Quartus II Compiler creates shared arithmetic chains longer than 20 ALMs (10 ALMs in arithmetic or shared arithmetic mode) by linking LABs together automatically. To enhance fitting, a long shared arithmetic chain runs vertically, allowing fast horizontal connections to the TriMatrix memory and DSP blocks. A shared arithmetic chain can continue as far as a full column.

Document Revision History

Date	Version	Changes
January 2014	2014.01.10	Added multiplexers for the bypass paths and register outputs in the following diagrams: • ALM High-Level Block Diagram for Arria V GX, GT, SX, and ST Devices • ALM High-Level Block Diagram for Arria V GZ Devices • Template for Supported 7-Input Functions in Extended LUT Mode for Arria V Devices • ALM in Arithmetic Mode for Arria V Devices • ALM in Shared Arithmetic Mode for Arria V Devices
May 2013	2013.05.06	• Added link to the known document issues in the Knowledge Base. • Updated local and direct link interconnects section to add M20K memory block. • Removed register chain outputs information in ALM output section. • Removed `reg_chain_in` and `reg_chain_out` ports in ALM high-level block diagram and ALM connection details diagram for Arria V GX, GT, SX, and ST devices.
November 2012	2012.11.19	• Added MLAB structure for Arria V GZ devices. • Added LAB-wide control signals diagram for Arria V GZ devices. • Added ALM high level block diagram for Arria V GZ devices. • Added ALM connection details diagram for Arria V GZ devices. • Reorganized content and updated template.
June 2012	2.0	Updated for the Quartus II software v12.0 release: • Restructured chapter. • Updated Figure 1–6.
November 2011	1.1	Restructured chapter.
May 2011	1.0	Initial release.

Embedded Memory Blocks in Arria V Devices

2

2015.01.23

AV-52002 Subscribe Send Feedback

The embedded memory blocks in the devices are flexible and designed to provide an optimal amount of small- and large-sized memory arrays to fit your design requirements.

Related Information

Arria V Device Handbook: Known Issues
Lists the planned updates to the *Arria V Device Handbook* chapters.

Types of Embedded Memory

The Arria V devices contain two types of memory blocks:

- 20 Kb M20K or 10 Kb M10K blocks—blocks of dedicated memory resources. The M20K and M10K blocks are ideal for larger memory arrays while still providing a large number of independent ports.
- 640 bit memory logic array blocks (MLABs)—enhanced memory blocks that are configured from dual-purpose logic array blocks (LABs). The MLABs are ideal for wide and shallow memory arrays. The MLABs are optimized for implementation of shift registers for digital signal processing (DSP) applications, wide shallow FIFO buffers, and filter delay lines. Each MLAB is made up of ten adaptive logic modules (ALMs). In the Arria V devices, you can configure these ALMs as ten 32 x 2 blocks, giving you one 32 x 20 simple dual-port SRAM block per MLAB. You can also configure these ALMs, in Arria V GZ devices, as ten 64 x 1 blocks, giving you one 64 x 10 simple dual-port SRAM block per MLAB.

Embedded Memory Capacity in Arria V Devices

Table 2-1: Embedded Memory Capacity and Distribution in Arria V Devices

Variant	Member Code	M20K		M10K		MLAB		Total RAM Bit (Kb)
		Block	RAM Bit (Kb)	Block	RAM Bit (Kb)	Block	RAM Bit (Kb)	
Arria V GX	A1	—	—	800	8,000	741	463	8,463

Embedded Memory Design Guidelines for Arria V Devices

There are several considerations that require your attention to ensure the success of your designs. Unless noted otherwise, these design guidelines apply to all variants of this device family.

Guideline: Consider the Memory Block Selection

The Quartus II software automatically partitions the user-defined memory into the memory blocks based on your design's speed and size constraints. For example, the Quartus II software may spread out the memory across multiple available memory blocks to increase the performance of the design.

To assign the memory to a specific block size manually, use the RAM megafunction in the MegaWizard™ Plug-In Manager.

For the memory logic array blocks (MLAB), you can implement single-port SRAM through emulation using the Quartus II software. Emulation results in minimal additional use of logic resources.

Because of the dual-purpose architecture of the MLAB, only data input and output registers are available in the block. The MLABs gain read address registers from the ALMs. However, the write address and read data registers are internal to the MLABs.

Guideline: Implement External Conflict Resolution

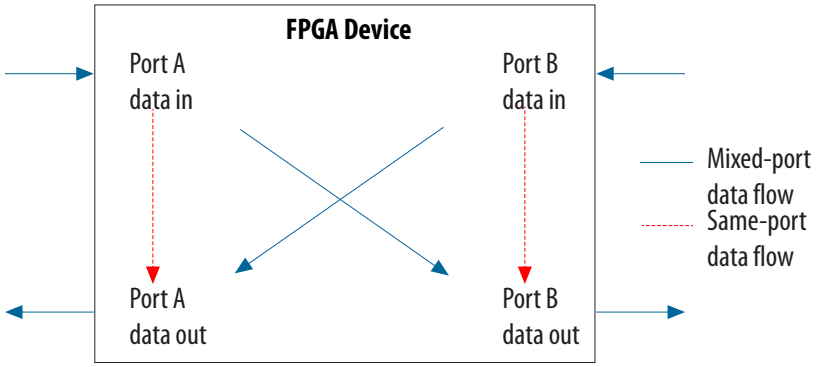
In the true dual-port RAM mode, you can perform two write operations to the same memory location. However, the memory blocks do not have internal conflict resolution circuitry. To avoid unknown data being written to the address, implement external conflict resolution logic to the memory block.

Guideline: Customize Read-During-Write Behavior

Customize the read-during-write behavior of the memory blocks to suit your design requirements.

Figure 2-1: Read-During-Write Data Flow

This figure shows the difference between the two types of read-during-write operations available—same port and mixed port.



Same-Port Read-During-Write Mode

The same-port read-during-write mode applies to a single-port RAM or the same port of a true dual-port RAM.

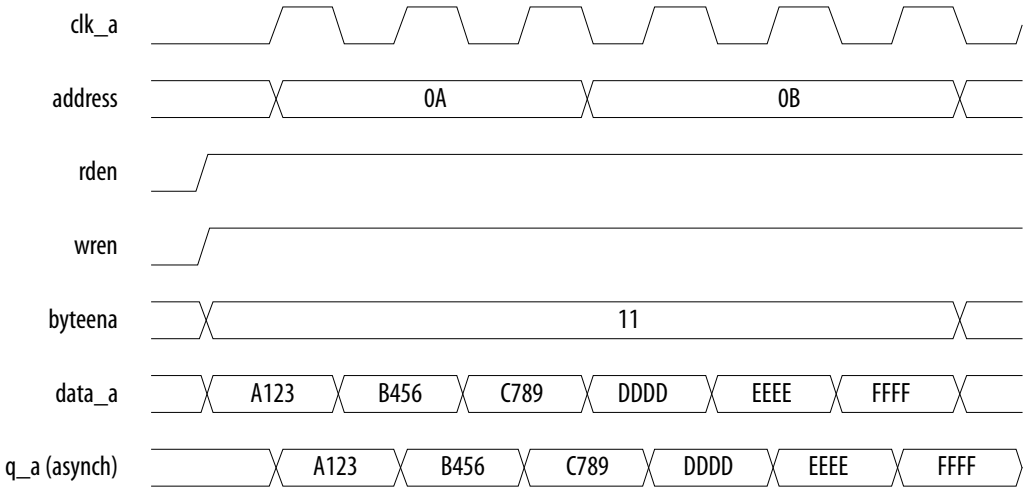
Table 2-2: Output Modes for Embedded Memory Blocks in Same-Port Read-During-Write Mode

This table lists the available output modes if you select the embedded memory blocks in the same-port read-during-write mode.

Output Mode	Memory Type	Description
"new data" (flow-through)	M20K, M10K	The new data is available on the rising edge of the same clock cycle on which the new data is written.
"don't care"	M10K, MLAB	The RAM outputs "don't care" values for a read-during-write operation.

Figure 2-2: Same-Port Read-During-Write: New Data Mode

This figure shows sample functional waveforms of same-port read-during-write behavior in the “new data” mode.



Mixed-Port Read-During-Write Mode

The mixed-port read-during-write mode applies to simple and true dual-port RAM modes where two ports perform read and write operations on the same memory address using the same clock—one port reading from the address, and the other port writing to it.

Table 2-3: Output Modes for RAM in Mixed-Port Read-During-Write Mode

Output Mode	Memory Type	Description
"new data"	MLAB	A read-during-write operation to different ports causes the MLAB registered output to reflect the “new data” on the next rising edge after the data is written to the MLAB memory. This mode is available only if the output is registered.
"old data"	M20K, M10K, MLAB	A read-during-write operation to different ports causes the RAM output to reflect the “old data” value at the particular address. For MLAB, this mode is available only if the output is registered.

Output Mode	Memory Type	Description
"don't care"	M20K, M10K, MLAB	The RAM outputs “don’t care” or “unknown” value. • For M20K or M10K memory, the Quartus II software does not analyze the timing between write and read operations. • For MLAB, the Quartus II software analyzes the timing between write and read operations by default. To disable this behavior, turn on the **Do not analyze the timing between write and read operation. Metastability issues are prevented by never writing and reading at the same address at the same time** option.
"constrained don't care"	MLAB	The RAM outputs “don’t care” or “unknown” value. The Quartus II software analyzes the timing between write and read operations in the MLAB.

Figure 2-3: Mixed-Port Read-During-Write: New Data Mode

This figure shows a sample functional waveform of mixed-port read-during-write behavior for the “new data” mode.

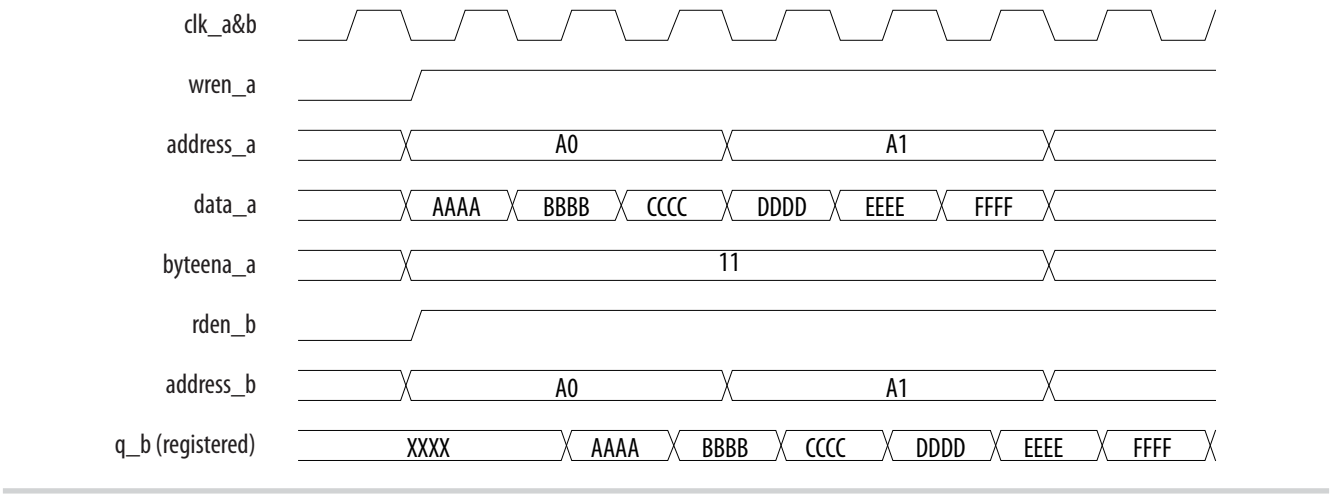


Figure 2-4: Mixed-Port Read-During-Write: Old Data Mode

This figure shows a sample functional waveform of mixed-port read-during-write behavior for the "old data" mode.

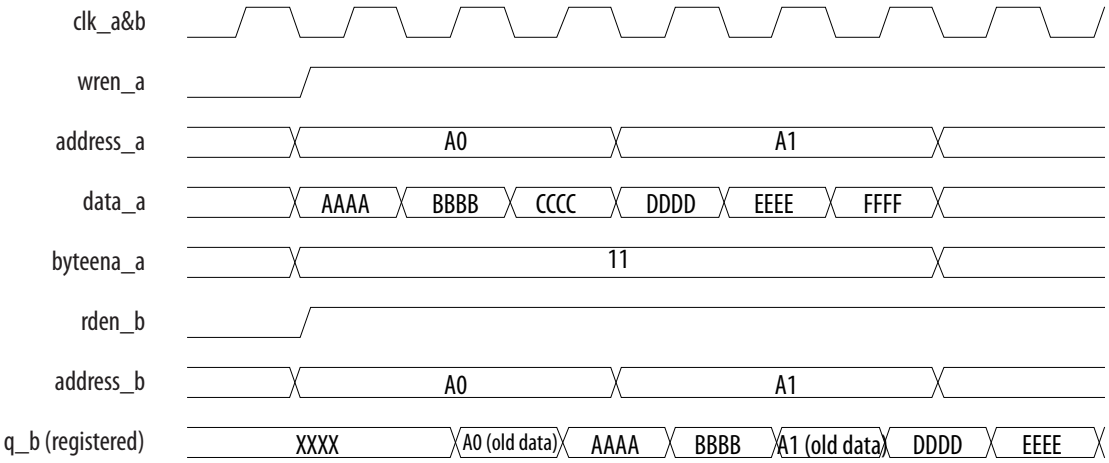

Figure 2-5: Mixed-Port Read-During-Write: Don't Care or Constrained Don't Care Mode

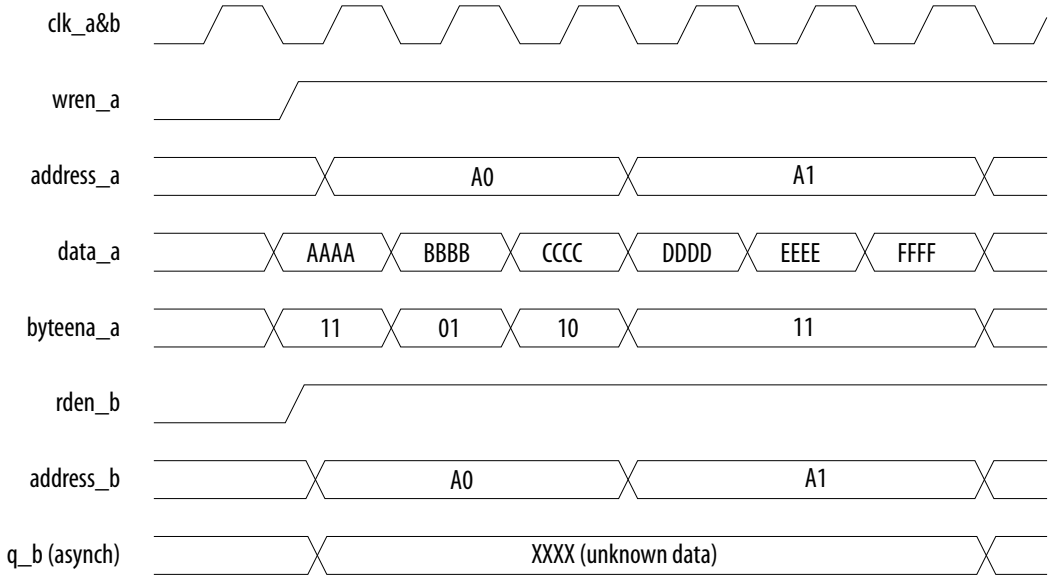
This figure shows a sample functional waveform of mixed-port read-during-write behavior for the "don't care" or "constrained don't care" mode.



In the dual-port RAM mode, the mixed-port read-during-write operation is supported if the input registers have the same clock. The output value during the operation is "unknown."

Related Information

Internal Memory (RAM and ROM) User Guide

Provides more information about the RAM megafunction that controls the read-during-write behavior.

Guideline: Consider Power-Up State and Memory Initialization

Consider the power up state of the different types of memory blocks if you are designing logic that evaluates the initial power-up values, as listed in the following table.

Table 2-4: Initial Power-Up Values of Embedded Memory Blocks

Memory Type	Output Registers	Power Up Value
MLAB	Used	Zero (cleared)
	Bypassed	Read memory contents
M20K, M10K	Used	Zero (cleared)
	Bypassed	Zero (cleared)

By default, the Quartus II software initializes the RAM cells in Arria V devices to zero unless you specify a **.mif**.

All memory blocks support initialization with a **.mif**. You can create **.mif** files in the Quartus II software and specify their use with the RAM megafunction when you instantiate a memory in your design. Even if a memory is pre-initialized (for example, using a **.mif**), it still powers up with its output cleared.

Related Information

- **Internal Memory (RAM and ROM) User Guide**
  Provides more information about **.mif** files.
- **Quartus II Handbook**
  Provides more information about **.mif** files.

Guideline: Control Clocking to Reduce Power Consumption

Reduce AC power consumption in your design by controlling the clocking of each memory block:

- Use the read-enable signal to ensure that read operations occur only when necessary. If your design does not require read-during-write, you can reduce your power consumption by deasserting the read-enable signal during write operations, or during the period when no memory operations occur.
- Use the Quartus II software to automatically place any unused memory blocks in low-power mode to reduce static power.

Embedded Memory Features

Table 2-5: Memory Features in Arria V Devices

This table summarizes the features supported by the embedded memory blocks.

Features	M20K, M10K	MLAB
Maximum operating frequency	M20K—600 MHz M10K—400 MHz	Arria V GX, GT, SX, and ST—500 MHz Arria V GZ—600 MHz

Features	M20K, M10K	MLAB
Capacity per block (including parity bits)	M20K—20,480 M10K—10,240	640
Parity bits	Supported	Supported
Byte enable	Supported	Supported
Packed mode	Supported	—
Address clock enable	Supported	Supported
Simple dual-port mixed width	Supported	—
True dual-port mixed width	Supported	—
FIFO buffer mixed width	Supported	—
Memory Initialization File (.mif)	Supported	Supported
Mixed-clock mode	Supported	Supported
Fully synchronous memory	Supported	Supported
Asynchronous memory	—	Only for flow-through read memory operations.
Power-up state	Output ports are cleared.	• Registered output ports—Cleared. • Unregistered output ports—Read memory contents.
Asynchronous clears	Output registers and output latches	Output registers and output latches
Write/read operation triggering	Rising clock edges	Rising clock edges
Same-port read-during-write	• M20K—output ports set to new data • M10K—output ports set to "new data" or "don't care" (The "don't care" mode applies only for the single-port RAM mode).	Output ports set to "don't care".
Mixed-port read-during-write	Output ports set to "old data" or "don't care".	Output ports set to "old data", "new data", "don't care", or "constrained don't care".

Features	M20K, M10K	MLAB
ECC support	Soft IP support using the Quartus II software. Built-in support in x32-wide simple dual-port mode (M20K only).	Soft IP support using the Quartus II software.

Embedded Memory Configurations

Table 2-6: Supported Embedded Memory Block Configurations for Arria V Devices

This table lists the maximum configurations supported for the embedded memory blocks. The information is applicable only to the single-port RAM and ROM modes.

Memory Block	Depth (bits)	Programmable Width
MLAB	32	x16, x18, or x20
	64(1)	x10
M20K	512	x40
	1K	x20
	2K	x10
	4K	x5
	8K	x2
	16K	x1
M10K	256	x40 or x32
	512	x20 or x16
	1K	x10 or x8
	2K	x5 or x4
	4K	x2
	8K	x1

Mixed-Width Port Configurations

The mixed-width port configuration is supported in the simple dual-port RAM and true dual-port RAM memory modes.

(1) Available for Arria V GZ devices only.

Note: MLABs do not support mixed-width port configurations.

Related Information

Internal Memory (RAM and ROM) User Guide
Provides more information about dual-port mixed width support.

M20K Blocks Mixed-Width Configurations

The following table lists the mixed-width configurations of the M20K blocks in the simple dual-port RAM mode.

Table 2-7: M20K Block Mixed-Width Configurations (Simple Dual-Port RAM Mode)

Read Port	Write Port									
	16K x 1	8K x 2	4K x 4	4K x 5	2K x 8	2K x 10	1K x 16	1K x 20	512 x 32	512 x 40

Embedded Memory Modes

Caution: To avoid corrupting the memory contents, do not violate the setup or hold time on any of the memory block input registers during read or write operations. This is applicable if you use the memory blocks in single-port RAM, simple dual-port RAM, true dual-port RAM, or ROM mode.

Table 2-11: Memory Modes Supported in the Embedded Memory Blocks

This table lists and describes the memory modes that are supported in the Arria V embedded memory blocks.

Memory Mode	M20K and M10K Support	MLAB Support	Description
Single-port RAM	Yes	Yes	You can perform only one read or one write operation at a time. Use the read enable port to control the RAM output ports behavior during a write operation: • To retain the previous values that are held during the most recent active read enable—create a read-enable port and perform the write operation with the read enable port deasserted. • To show the new data being written, the old data at that address, or a "Don't Care" value when read-during-write occurs at the same address location—do not create a read-enable signal, or activate the read enable during a write operation.
Simple dual-port RAM	Yes	Yes	You can simultaneously perform one read and one write operations to different locations where the write operation happens on port A and the read operation happens on port B.
True dual-port RAM	Yes	—	You can perform any combination of two port operations: two reads, two writes, or one read and one write at two different clock frequencies.
Shift-register	Yes	Yes	You can use the memory blocks as a shift-register block to save logic cells and routing resources. This is useful in DSP applications that require local data storage such as finite impulse response (FIR) filters, pseudo-random number generators, multi-channel filtering, and auto- and cross- correlation functions. Traditionally, the local data storage is implemented with standard flip-flops that exhaust many logic cells for large shift registers. The input data width (w), the length of the taps (m), and the number of taps (n) determine the size of a shift register ($w \times m \times n$). You can cascade memory blocks to implement larger shift registers.

Memory Mode	M20K and M10K Support	MLAB Support	Description
ROM	Yes	Yes	You can use the memory blocks as ROM. • Initialize the ROM contents of the memory blocks using a **.mif** or **.hex**. • The address lines of the ROM are registered on M20K or M10K blocks but can be unregistered on MLABs. • The outputs can be registered or unregistered. • The output registers can be asynchronously cleared. • The ROM read operation is identical to the read operation in the single-port RAM configuration.
FIFO	Yes	Yes	You can use the memory blocks as FIFO buffers. Use the SCFIFO and DCFIFO megafunctions to implement single- and dual-clock asynchronous FIFO buffers in your design. For designs with many small and shallow FIFO buffers, the MLABs are ideal for the FIFO mode. However, the MLABs do not support mixed-width FIFO mode.

Embedded Memory Clocking Modes

This section describes the clocking modes for the Arria V memory blocks.

Caution: To avoid corrupting the memory contents, do not violate the setup or hold time on any of the memory block input registers during read or write operations.

Clocking Modes for Each Memory Mode

Table 2-12: Memory Blocks Clocking Modes Supported for Each Memory Mode

Clocking Mode	Memory Mode				
	Single-Port	Simple Dual-Port	True Dual-Port	ROM	FIFO
Single clock mode	Yes	Yes	Yes	Yes	Yes
Read/write clock mode	—	Yes	—	—	Yes

Clocking Mode	Memory Mode				
	Single-Port	Simple Dual-Port	True Dual-Port	ROM	FIFO
Input/output clock mode	Yes	Yes	Yes	Yes	—
Independent clock mode	—	—	Yes	Yes	—

Note: The clock enable signals are not supported for write address, byte enable, and data input registers on MLAB blocks.

Single Clock Mode

In the single clock mode, a single clock, together with a clock enable, controls all registers of the memory block.

Read/Write Clock Mode

In the read/write clock mode, a separate clock is available for each read and write port. A read clock controls the data-output, read-address, and read-enable registers. A write clock controls the data-input, write-address, write-enable, and byte enable registers.

Input/Output Clock Mode

In input/output clock mode, a separate clock is available for each input and output port. An input clock controls all registers related to the data input to the memory block including data, address, byte enables, read enables, and write enables. An output clock controls the data output registers.

Independent Clock Mode

In the independent clock mode, a separate clock is available for each port (A and B). Clock A controls all registers on the port A side; clock B controls all registers on the port B side.

Note: You can create independent clock enable for different input and output registers to control the shut down of a particular register for power saving purposes. From the parameter editor, click **More Options** (beside the clock enable option) to set the available independent clock enable that you prefer.

Asynchronous Clears in Clocking Modes

In all clocking modes, asynchronous clears are available only for output latches and output registers. For the independent clock mode, this is applicable on both ports.

Output Read Data in Simultaneous Read/Write

If you perform a simultaneous read/write to the same address location using the read/write clock mode, the output read data is unknown. If you require the output read data to be a known value, use single-clock or input/output clock mode and select the appropriate read-during-write behavior in the MegaWizard™ Plug-In Manager.

Note: MLAB memory blocks only support simultaneous read/write operations when operating in single clock mode.

Independent Clock Enables in Clocking Modes

Independent clock enables are supported in the following clocking modes:

- Read/write clock mode—supported for both the read and write clocks.
- Independent clock mode—supported for the registers of both ports.

To save power, you can control the shut down of a particular register using the clock enables.

Guideline: Control Clocking to Reduce Power Consumption on page 2-7

Parity Bit in Memory Blocks

Table 2-13: Parity Bit Support for the Embedded Memory Blocks

This table describes the parity bit support for the memory blocks.

M20K, M10K	MLAB
• The parity bit is the fifth bit associated with each 4 data bits in data widths of 5, 10, 20, and 40 (bits 4, 9, 14, 19, 24, 29, 34, and 39). • In non-parity data widths, the parity bits are skipped during read or write operations. • Parity function is not performed on the parity bit.	• The parity bit is the ninth bit associated with each byte. • The ninth bit can store a parity bit or serve as an additional bit. • Parity function is not performed on the parity bit.

Byte Enable in Embedded Memory Blocks

The embedded memory blocks support byte enable controls:

- The byte enable controls mask the input data so that only specific bytes of data are written. The unwritten bytes retain the values written previously.
- The write enable (`wren`) signal, together with the byte enable (`byteena`) signal, control the write operations on the RAM blocks. By default, the `byteena` signal is high (enabled) and only the `wren` signal controls the writing.
- The byte enable registers do not have a `clear` port.
- If you are using parity bits, on the M20K and M10K blocks, the byte enable function controls 8 data bits and 2 parity bits; on the MLABs, the byte enable function controls all 10 bits in the widest mode.
- The MSB and LSB of the `byteena` signal correspond to the MSB and LSB of the data bus, respectively.
- The byte enables are active high.

Byte Enable Controls in Memory Blocks

Table 2-14: byteena Controls in x20 Data Width

byteena[1:0]	Data Bits Written	
11 (default)	[19:10]	[9:0]
10	[19:10]	—
01	—	[9:0]

Table 2-15: byteena Controls in x40 Data Width

byteena[3:0]	Data Bits Written			
1111 (default)	[39:30]	[29:20]	[19:10]	[9:0]
1000	[39:30]	—	—	—
0100	—	[29:20]	—	—
0010	—	—	[19:10]	—
0001	—	—	—	[9:0]

Note: If you use the ECC feature on the M20K blocks, you cannot use the byte enable feature.

Data Byte Output

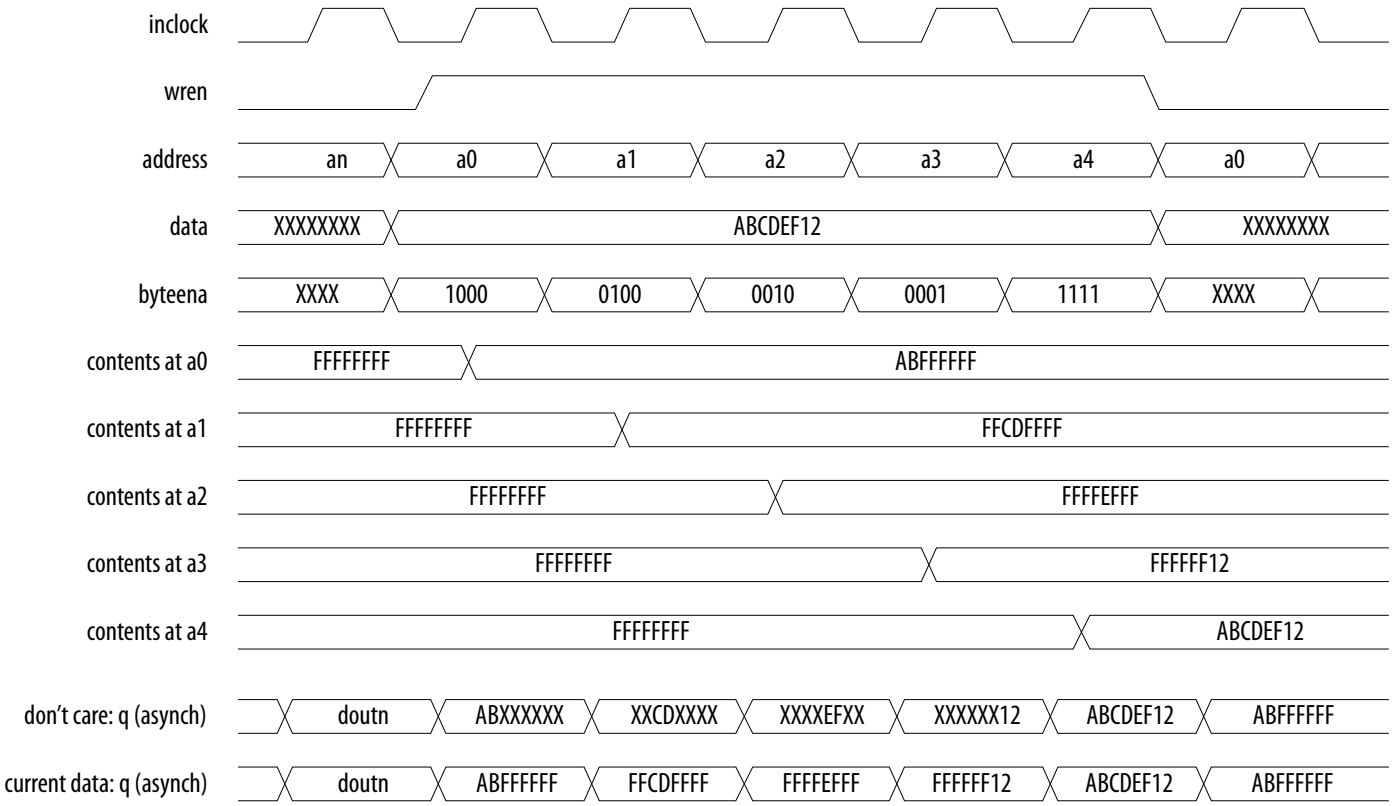
In M10K blocks, the corresponding masked data byte output appears as a “don’t care” value.

In M20K blocks or MLABs, when you de-assert a byte-enable bit during a write cycle, the corresponding data byte output appears as either a “don't care” value or the current data at that location. You can control the output value for the masked byte in the M20K blocks or MLABs by using the Quartus II software.

RAM Blocks Operations

Figure 2-6: Byte Enable Functional Waveform

This figure shows how the `wren` and `byteena` signals control the operations of the RAM blocks. For the M10K blocks, the write-masked data byte output appears as a "don't care" value because the "current data" value is not supported.



Memory Blocks Packed Mode Support

The M20K and M10K memory blocks support packed mode.

The packed mode feature packs two independent single-port RAM blocks into one memory block. The Quartus II software automatically implements packed mode where appropriate by placing the physical RAM block in true dual-port mode and using the MSB of the address to distinguish between the two logical RAM blocks. The size of each independent single-port RAM must not exceed half of the target block size.

Memory Blocks Address Clock Enable Support

The embedded memory blocks support address clock enable, which holds the previous address value for as long as the signal is enabled (`addressstall = 1`). When the memory blocks are configured in dual-port mode, each port has its own independent address clock enable. The default value for the address clock enable signal is low (disabled).

Figure 2-7: Address Clock Enable

This figure shows an address clock enable block diagram. The address clock enable is referred to by the port name `addressstall`.

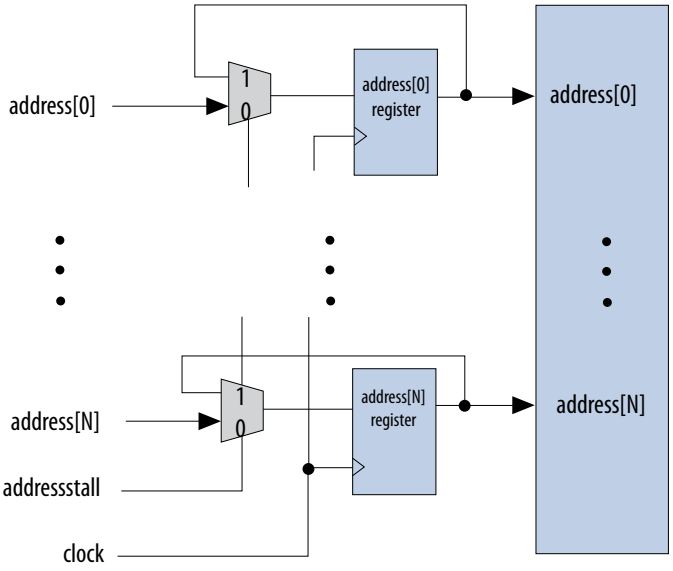


Figure 2-8: Address Clock Enable During Read Cycle Waveform

This figure shows the address clock enable waveform during the read cycle.

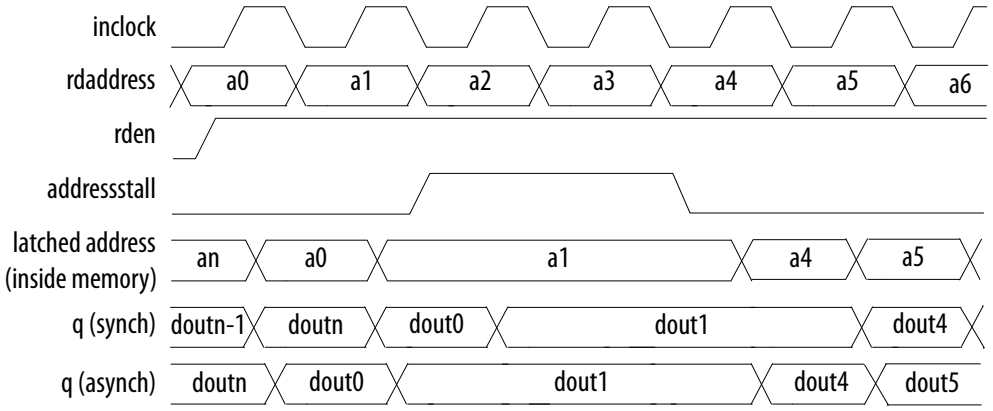

Figure 2-9: Address Clock Enable During the Write Cycle Waveform

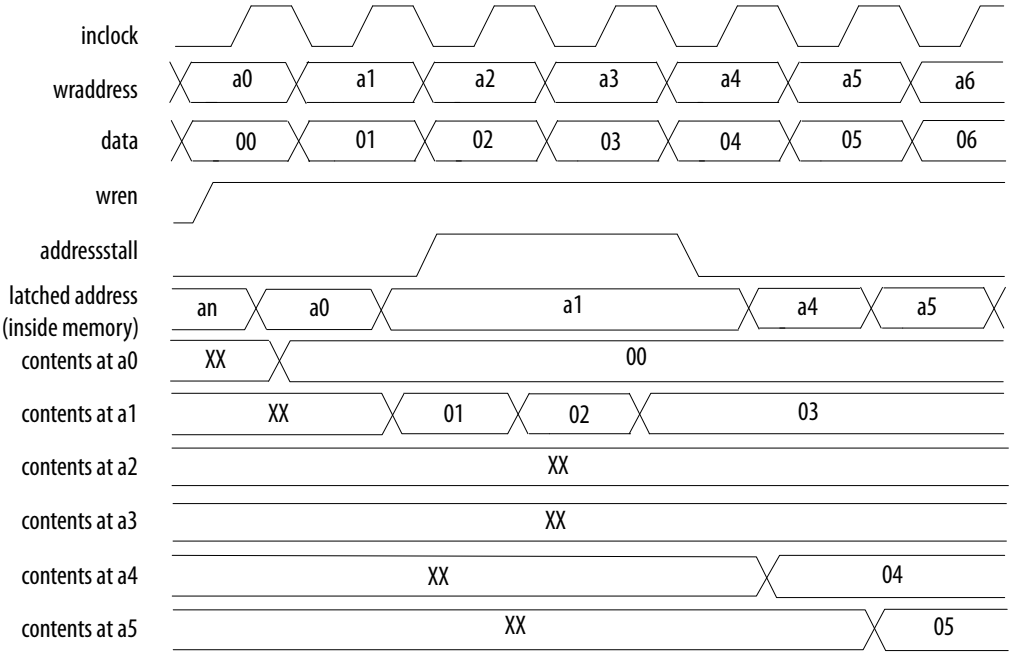
This figure shows the address clock enable waveform during the write cycle.



Memory Blocks Error Correction Code Support

ECC allows you to detect and correct data errors at the output of the memory. ECC can perform single-error correction, double-adjacent-error correction, and triple-adjacent-error detection in a 32-bit word. However, ECC cannot detect four or more errors.

The M20K blocks have built-in support for ECC when in x32-wide simple dual-port mode:

- The M20K runs slower than non-ECC simple-dual port mode when ECC is engaged. However, you can enable optional ECC pipeline registers before the output decoder to achieve the same performance as non-ECC simple-dual port mode at the expense of one cycle of latency.
- The M20K ECC status is communicated with two ECC status flag signals—e (error) and ue (uncorrectable error). The status flags are part of the regular output from the memory block. When ECC is engaged, you cannot access two of the parity bits because the ECC status flag replaces them.

Error Correction Code Truth Table

Table 2-16: ECC Status Flags Truth Table

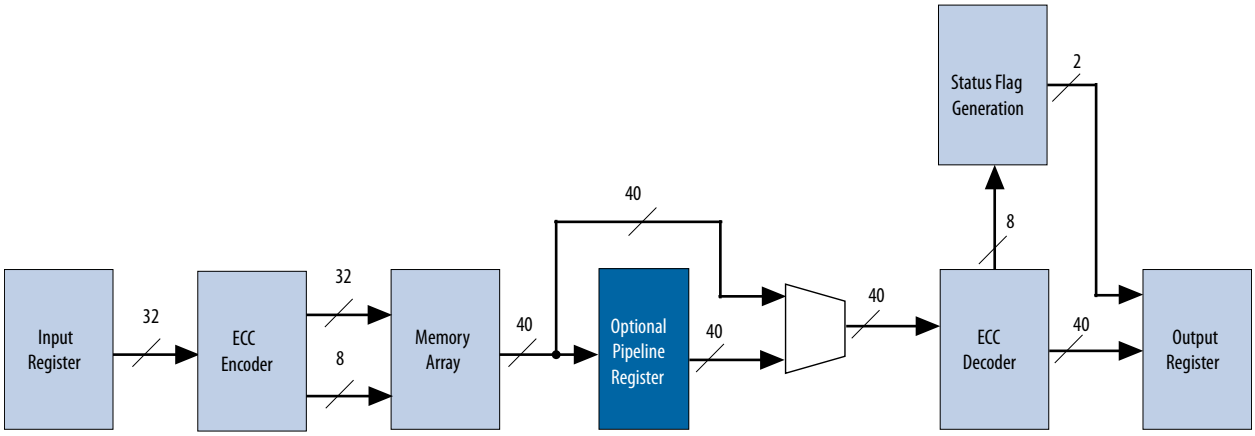
e (error) `eccstatus[1]`	ue (uncorrectable error) `eccstatus[0]`	Status
0	0	No error.
0	1	Illegal.

e (error) eccstatus[1]	ue (uncorrectable error) eccstatus[0]	Status
1	0	A correctable error occurred and the error has been corrected at the outputs; however, the memory array has not been updated.
1	1	An uncorrectable error occurred and uncorrectable data appears at the outputs.

If you engage ECC:

- You cannot use the byte enable feature.
- Read-during-write old data mode is not supported.

Figure 2-10: ECC Block Diagram for M20K Memory



Document Revision History

Date	Version	Changes
January 2015	2015.01.23	• Reword Total RAM bits in Memory Features in Arria V Devices table to Capacity per Block.
June 2014	2014.06.30	Added information about MLAB memory blocks support for simultaneous read/write operations. MLAB memory blocks only support simultaneous read/write operations when operating in single clock mode.

Date	Version	Changes
May 2013	2013.05.06	• Moved all links to the Related Information section of respective topics for easy reference. • Added link to the known document issues in the Knowledge Base. • Corrected the description about the "don't care" output mode for RAM in mixed-port read-during-write. • Reorganized the structure of the supported memory configurations topics (single-port and mixed-width dual-port) to improve clarity about maximum data widths supported for each configuration. • Added a description to the table listing the maximum embedded memory configurations to clarify that the information applies only to the single port or ROM mode. • Removed the topic about mixed-width configurations for MLABs and added a note to clarify that MLABs do not support mixed-width configuration.
November 2012	2012.11.19	• Reorganized content and updated template. • Added information for Arria V GZ including M20K memory, memory features, and memory capacity. • Added and updated memory capacity information from the *Arria V Device Overview* for easy reference. • Moved information about supported memory block configurations into its own table. • Added short descriptions of each clocking mode. • Added topic about the packed mode support. • Added topic about the address clock enable support. • Added topic about ECC support and the ECC truth table.
June 2012	2.0	• Restructured the chapter. • Updated the “Memory Modes”, “Clocking Modes”, and “Design Considerations” sections. • Updated Table 2–1. • Added the “Parity Bit” and “Byte Enable” sections. • Moved the memory capacity information to the *Arria V Device Overview*.
November 2011	1.1	• Updated Table 2–1. • Restructured chapter.
May 2011	1.0	Initial release.

Variable Precision DSP Blocks in Arria V Devices

3

2015.01.23

AV-52003 Subscribe Send Feedback

This chapter describes how the variable-precision digital signal processing (DSP) blocks in Arria V devices are optimized to support higher bit precision in high-performance DSP applications.

Related Information

Arria V Device Handbook: Known Issues
Lists the planned updates to the *Arria V Device Handbook* chapters.

Features

The Arria V variable precision DSP blocks offer the following features:

- High-performance, power-optimized, and fully registered multiplication operations
- 9-bit, 18-bit, 27-bit, and 36-bit word lengths
- 18 x 19 and 18 x 25 complex multiplications
- Built-in addition, subtraction, and 64-bit accumulation unit to combine multiplication results
- Cascading 19-bit or 27-bit to form the tap-delay line for filtering applications
- Cascading 64-bit output bus to propagate output results from one block to the next block without external logic support
- Hard pre-adder supported in 18-bit, 19-bit, and 27-bit mode for symmetric filters
- Internal coefficient register bank for filter implementation
- 18-bit and 27-bit systolic finite impulse response (FIR) filters with distributed output adder

	B5	1,090	3,270	2,180	1,090	—	1,090	1,090
Arria V ST	D3	809	2,427	1,618	809	—	809	809
	D5	1,090	3,270	2,180	1,090	—	1,090	1,090

Design Considerations

You should consider the following elements in your design:

- Operational modes
- Internal coefficient and pre-adder
- Accumulator
- Chainout adder

Operational Modes

The Quartus II software includes megafunctions that you can use to control the operation mode of the multipliers. After entering the parameter settings with the MegaWizard Plug-In Manager, the Quartus II software automatically configures the variable precision DSP block.

Altera provides two methods for implementing various modes of the Arria V variable precision DSP block in a design—using the Quartus II DSP megafunction and HDL inferring.

The following Quartus II megafunctions are supported for the Arria V variable precision DSP blocks implementation:

- LPM_MULT
- ALTERA_MULT_ADD
- ALTMULT_COMPLEX

- **Quartus II Software Help**

Internal Coefficient and Pre-Adder

To use the pre-adder feature, all input data and multipliers must have the same clock setting.

The input cascade support is not available when you enable the pre-adder feature.

Table 3-4: Internal Coefficient and Pre-Adder Features in Arria V Devices

Mode	Arria V GX, GT, SX, and ST	Arria V GZ
18-bit	The coefficient feature and pre-adder feature can be used independently.	The coefficient feature must be enabled when the pre-adder feature is enabled.
27-bit	The coefficient feature and pre-adder feature can be used independently.	The coefficient feature and pre-adder feature can be used independently. With pre-adder enabled: • If the multiplicand input comes from dynamic input due to width limitation in the input registers—the input data width is restricted to 22 bits. • If the multiplicand input comes from the internal coefficients—the data width of the multiplicand is 27 bits.

Note: When you enable the pre-adder feature, all input data must have the same clock setting.

Accumulator

The accumulator in the Arria V GX, GT, SX, and ST devices supports double accumulation by enabling the 64-bit double accumulation registers located between the output register bank and the accumulator.

The double accumulation registers are set statically in the programming file.

The accumulator in the Arria V GZ devices does not support double accumulation. The accumulator feature is not available in multi-block modes.

Chainout Adder

You can use the output chaining path to add results from other DSP blocks.

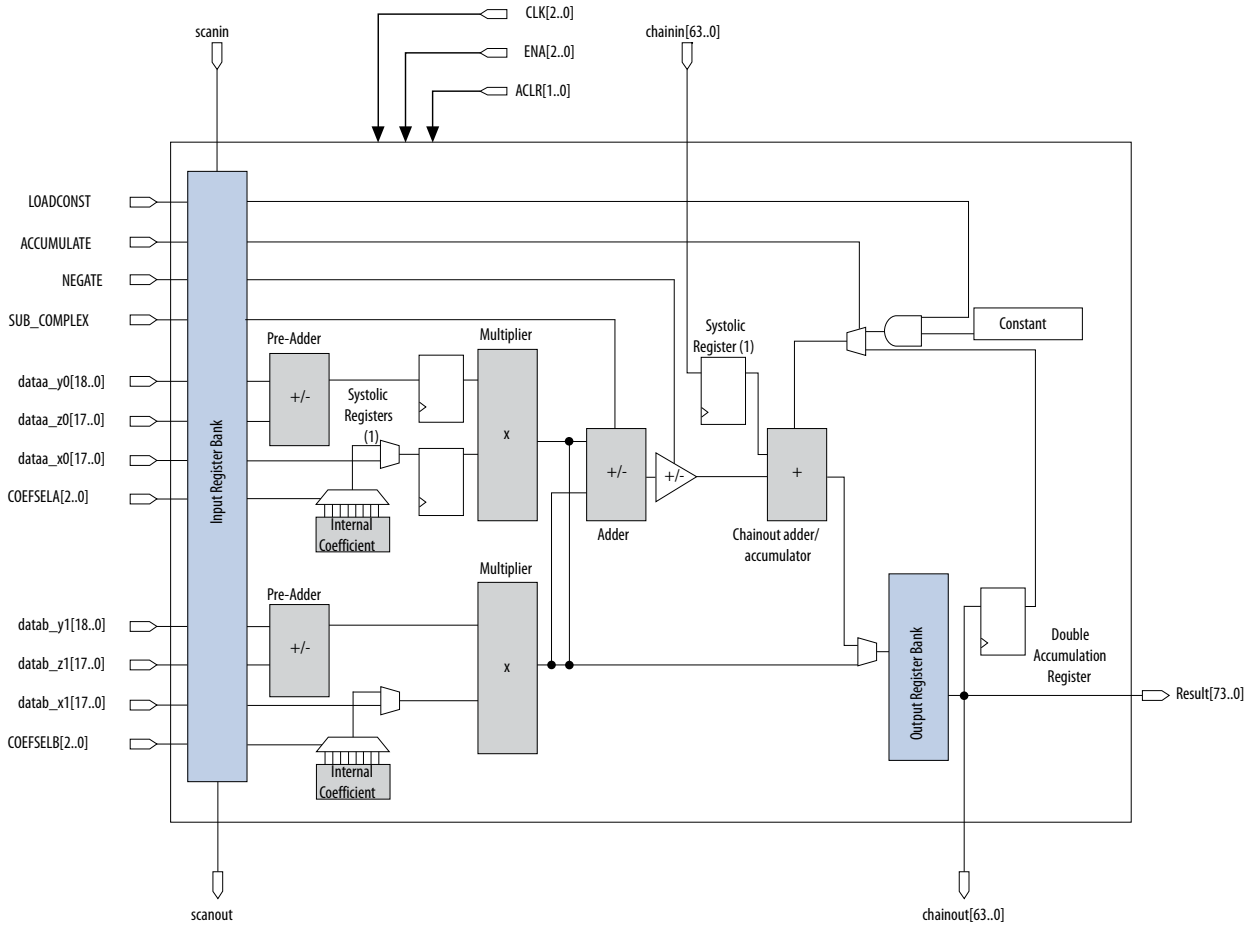
Block Architecture

The Arria V variable precision DSP block consists of the following elements:

- Input register bank
- Pre-adder
- Internal coefficient
- Multipliers
- Adder
- Accumulator and chainout adder
- Systolic registers
- Double accumulation register
- Output register bank

If the variable precision DSP block is not configured in systolic FIR mode, both systolic registers are bypassed.

Figure 3-1: Variable Precision DSP Block Architecture in 18 x 19 Mode for Arria V GX, GT, SX, and ST Devices



Note:
1. When enabled, systolic registers are clocked with the same clock source as the output register bank.

Figure 3-2: Variable Precision DSP Block Architecture in 27 x 27 Mode for Arria V GX, GT, SX, and ST Devices

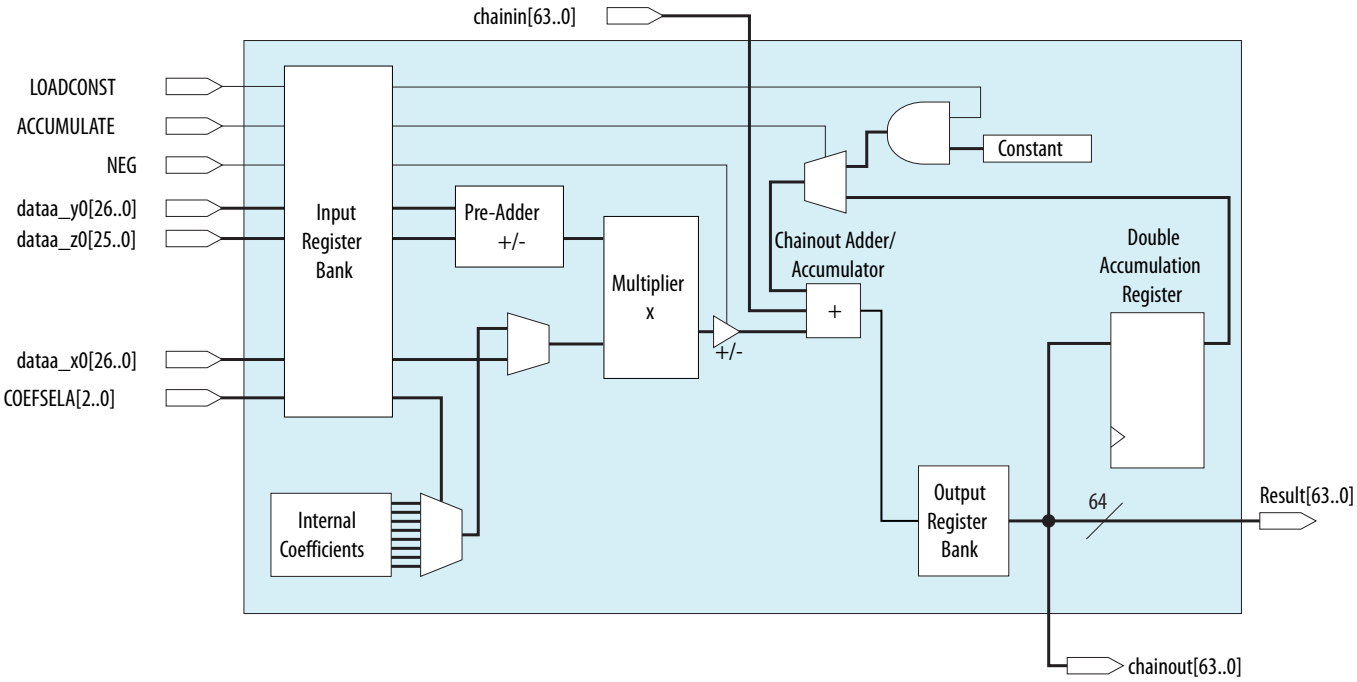


Figure 3-3: Variable Precision DSP Block Architecture in 18 x 18 Mode for Arria V GZ Devices

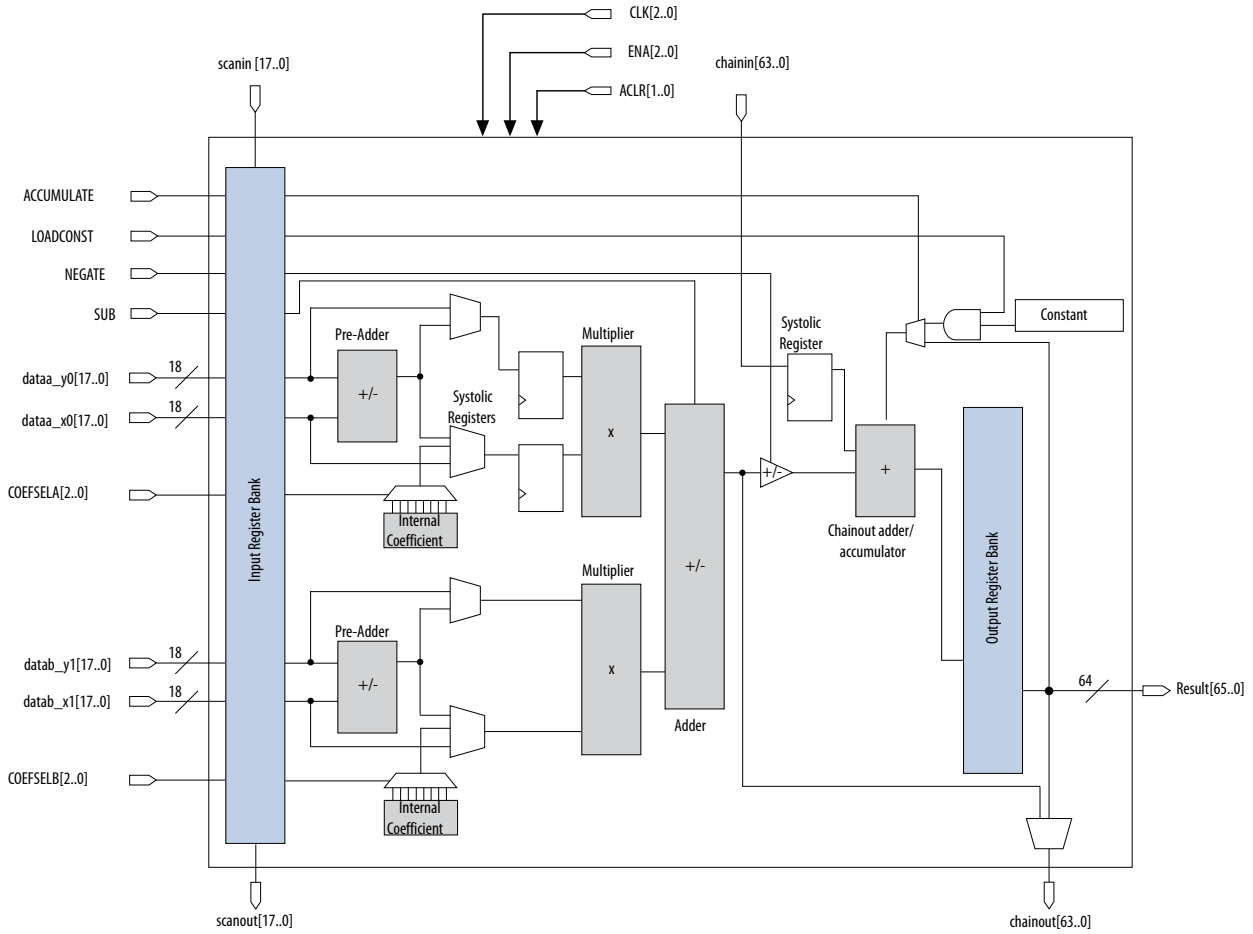

Figure 3-4: Variable Precision DSP Block Architecture in 27 x 27 Mode for Arria V GZ Devices

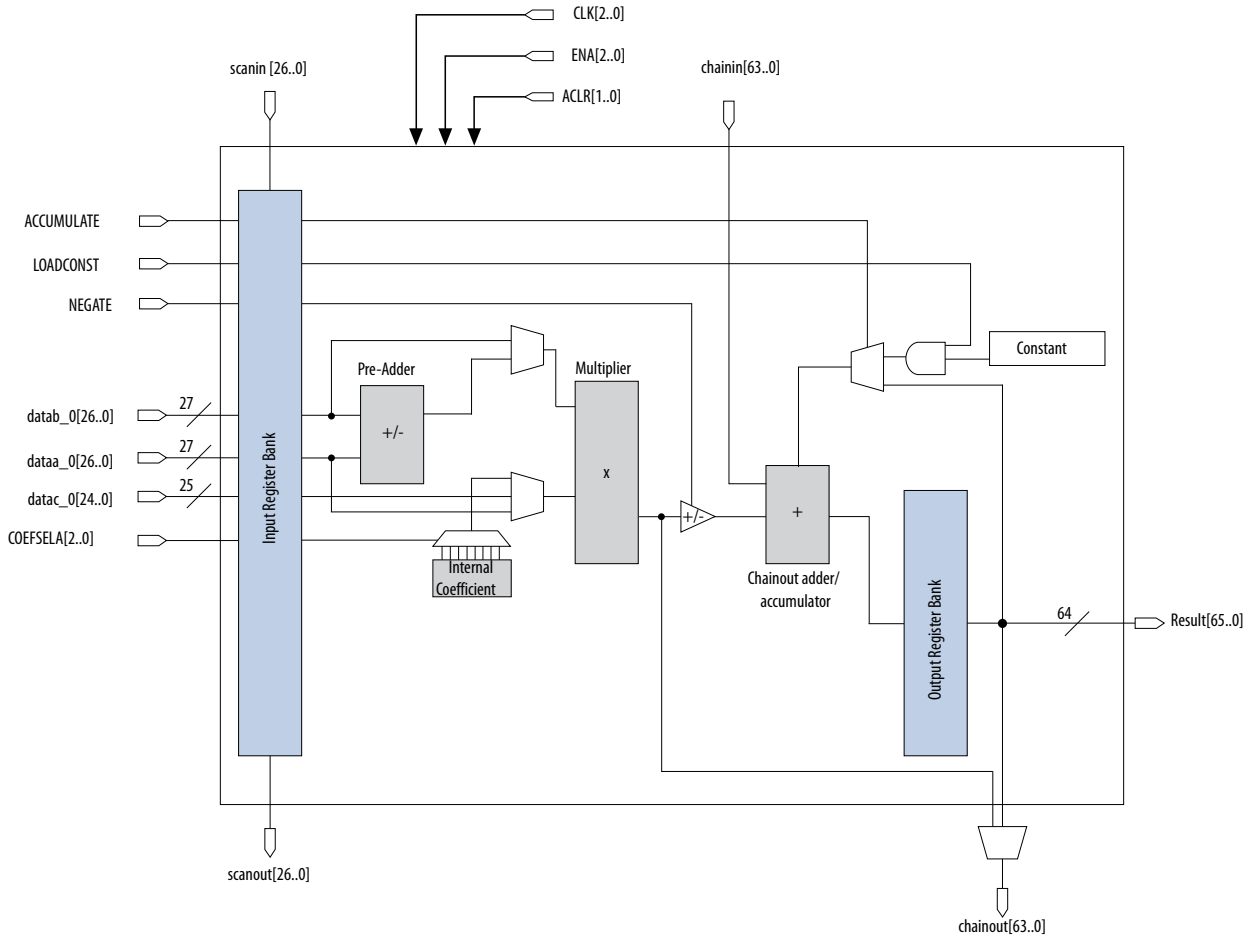

Input Register Bank

The input register bank consists of data, dynamic control signals, and two sets of delay registers.

All the registers in the DSP blocks are positive-edge triggered and cleared on power up. Each multiplier operand can feed an input register or a multiplier directly, bypassing the input registers.

The following variable precision DSP block signals control the input registers within the variable precision DSP block:

- `CLK[2..0]`
- `ENA[2..0]`
- `ACLR[0]`

In 18 x 18 and 18 x 19 mode, you can use the delay registers to balance the latency requirements when you use both the input cascade and chainout features.

The tap-delay line feature allows you to drive the top leg of the multiplier inputs from general routing or from the cascade chain. The following inputs can be driven from either the general routing or from the cascade chain:

- For Arria V GX, GT, SX, and ST devices:
  - `dataa_y0` and `datab_y1` in 18 x 19 mode
  - `dataa_y0` in 27 x 27 mode
- For Arria V GZ devices:
  - `dataa_y0[17..0]` and `datab_y1[17..0]` in 18 x 18 mode
  - `dataa_y0` in 27 x 27 mode

The Arria V GZ variable precision DSP block support 18-bit and 27-bit input cascading.

These figures show the input registers for Arria V devices.

Figure 3-5: Input Register of a Variable Precision DSP Block in 18 x 19 Mode for Arria V GX, GT, SX, and ST Devices

The figures show the data registers only. Registers for the control signals are not shown.

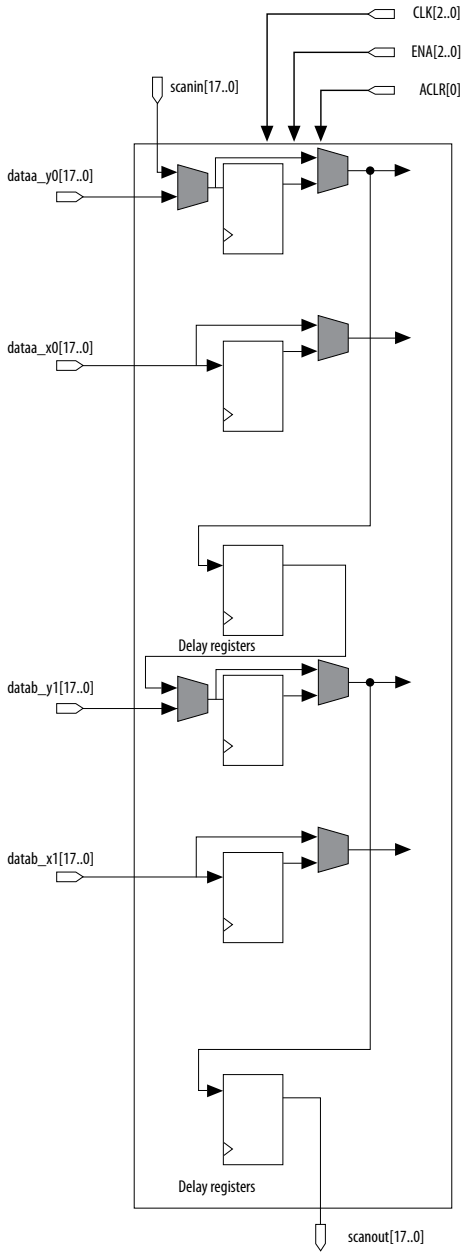

Figure 3-8: Input Register of a Variable Precision DSP Block in 27 x 27 Mode for Arria V GZ Devices

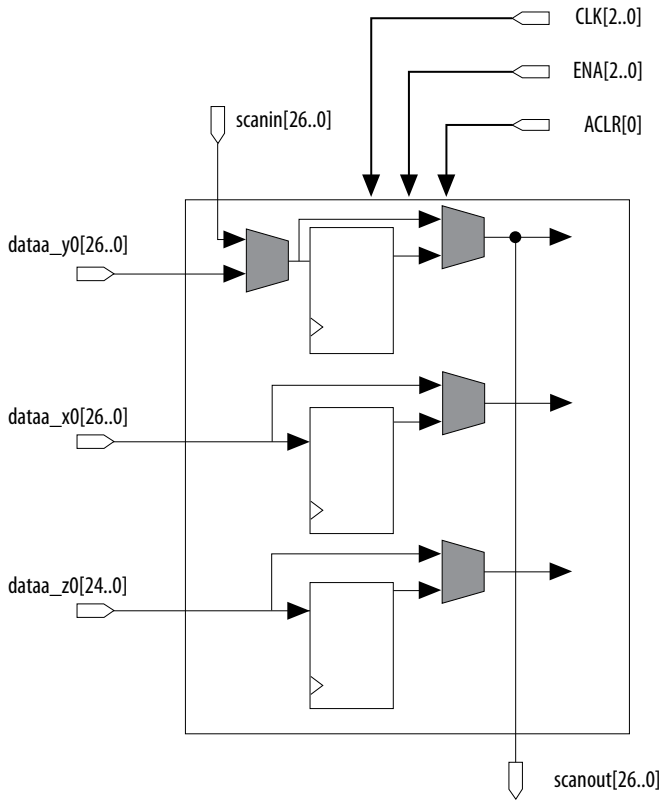
The figures show the data registers only. Registers for the control signals are not shown.



Pre-Adder

Arria V GX, GT, SX, and ST Devices

Each variable precision DSP block has two 19-bit pre-adders. You can configure these pre-adders in the following configurations:

- Two independent 19-bit pre-adders
- One 27-bit pre-adder

The pre-adder supports both addition and subtraction in the following input configurations:

- 18-bit (signed) addition or subtraction for 18 x 19 mode
- 17-bit (unsigned) addition or subtraction for 18 x 19 mode
- 26-bit addition or subtraction for 27 x 27 mode

Arria V GZ Devices

Each variable precision DSP block has two 18-bit pre-adders. You can configure these pre-adders in the following configurations:

- Two independent 18-bit adders
- One 26-bit adder

The pre-adder supports both addition and subtraction in the following input configurations:

- 17-bit addition or subtraction for 18-bit applications
- 25-bit addition or subtraction for 27-bit applications

Internal Coefficient

The Arria V variable precision DSP block has the flexibility of selecting the multiplicand from either the dynamic input or the internal coefficient.

The internal coefficient can support up to eight constant coefficients for the multiplicands in 18-bit and 27-bit modes. When you enable the internal coefficient feature, `COEFSELA`/`COEFSELB` are used to control the selection of the coefficient multiplexer.

Multipliers

A single variable precision DSP block can perform many multiplications in parallel, depending on the data width of the multiplier.

There are two multipliers per variable precision DSP block. You can configure these two multipliers in several operational modes.

For Arria V GX, GT, SX, and ST devices:

- One 27 x 27 multiplier
- Two 18 (signed)/(unsigned) x 19 (signed) multipliers
- Three 9 x 9 multipliers

For Arria V GZ devices:

- One 27 x 27 multiplier
- Two individual 16 x 16 multipliers
- Two individual 18 x 18 partial multipliers, with only 32-bit LSB multiplication result for each multiplication
- One individual 18 x 18 multiplier, with full 36-bit multiplication result
- One individual 27 x 27 multiplier
- One individual 36 x 18 multiplier
- There individual 9 x 9 multipliers

For Arria V GZ devices, you can use two adjacent DSP blocks to construct an individual 36-bit multiplier.

Related Information

Operational Mode Descriptions on page 3-19
Provides more information about the operational modes of the multipliers.

Adder

You can use the adder in various sizes, depending on the operational mode:

- One 64-bit adder with the 64-bit accumulator
- Two 18 x 19 modes—the adder is divided into two 37-bit adders to produce the full 37-bit result of each independent 18 x 19 multiplication
- Three 9 x 9 modes—you can use the adder as three 18-bit adders to produce three 9 x 9 multiplication results independently

Accumulator and Chainout Adder

The Arria V variable precision DSP block supports a 64-bit accumulator and a 64-bit adder.

For Arria V GX, GT, SX, and ST devices, the accumulator and chainout adder features are not supported in two independent 18 x 19 modes and three independent 9 x 9 modes.

For Arria V GZ devices, you can use the 64-bit adder as full adder.

The following signals can dynamically control the function of the accumulator:

- NEGATE
- LOADCONST
- ACCUMULATE

Table 3-5: Accumulator Functions and Dynamic Control Signals

This table lists the dynamic signals settings and description for each function. In this table, X denotes a "don't care" value.

Function	Description	NEGATE	LOADCONST	ACCUMULATE
Zeroing	Disables the accumulator.	0	0	0
Preload	Loads an initial value to the accumulator. Only one bit of the 64-bit preload value can be “1”. It can be used as rounding the DSP result to any position of the 64-bit result.	0	1	0
Accumulation	Adds the current result to the previous accumulate result.	0	X	1
Decimation	This function takes the current result, converts it into two’s complement, and adds it to the previous result.	1	X	1

Systolic Registers

There are two systolic registers per variable precision DSP block. If the variable precision DSP block is not configured in systolic FIR mode, both systolic registers are bypassed.

The first set of systolic registers consists of the following registers:

- 18-bit and 19-bit registers that are used to register the 18-bit and 19-bit inputs of the upper multiplier respectively for Arria V GX, GT, SX, and ST devices
- 18-bit registers that are used to register the 18-bit inputs of the upper multiplier for Arria V GZ devices

The second set of systolic registers are used to delay the chainout output to the next variable precision DSP block.

You must clock all the systolic registers with the same clock source as the output register bank.

Double Accumulation Register

The double accumulation register is an extra register in the feedback path of the accumulator. Enabling the double accumulation register will cause an extra clock cycle delay in the feedback path of the accumulator.

This register has the same `CLK`, `ENA`, and `ACLR` settings as the output register bank.

By enabling this register, you can have two accumulator channels using the same number of variable precision DSP block.

Double accumulation register is not available in Arria V GZ devices.

Output Register Bank

The positive edge of the clock signal triggers the 64-bit bypassable output register bank and is cleared after power up.

The following variable precision DSP block signals control the output register per variable precision DSP block:

- `CLK[2..0]`
- `ENA[2..0]`
- `ACLR[1]`

Operational Mode Descriptions

This section describes how you can configure an Arria V variable precision DSP block to efficiently support the following operational modes:

- Independent Multiplier Mode
- Independent Complex Multiplier Mode
- Multiplier Adder Sum Mode
- Sum of Square Mode (Arria V GZ only)
- 18 x 18 Multiplication Summed with 36-Bit Input Mode
- Systolic FIR Mode

Independent Multiplier Mode

In independent input and output multiplier mode, the variable precision DSP blocks perform individual multiplication operations for general purpose multipliers.

Table 3-6: Variable Precision DSP Block Independent Multiplier Mode Configurations for Arria V Devices

Configuration	Multipliers per block	Device Variant Support
9 x 9	3	All
16 x 16	1	Arria V GZ

Configuration	Multipliers per block	Device Variant Support
18 x 18 (partial)	1	Arria V GZ
18 x 18	1	Arria V GZ
18 (signed) x 18 (unsigned)	2	Arria V GX, GT, SX, ST
18 (unsigned) x 18 (unsigned)	2	Arria V GX, GT, SX, ST
18 (signed) x 19 (signed)	2	Arria V GX, GT, SX, ST
18 (unsigned) x 19 (signed)	2	Arria V GX, GT, SX, ST
18 x 25	1	Arria V GX, GT, SX, ST
20 x 24	1	Arria V GX, GT, SX, ST
27 x 27	1	All
36 x 18	1	Arria V GZ

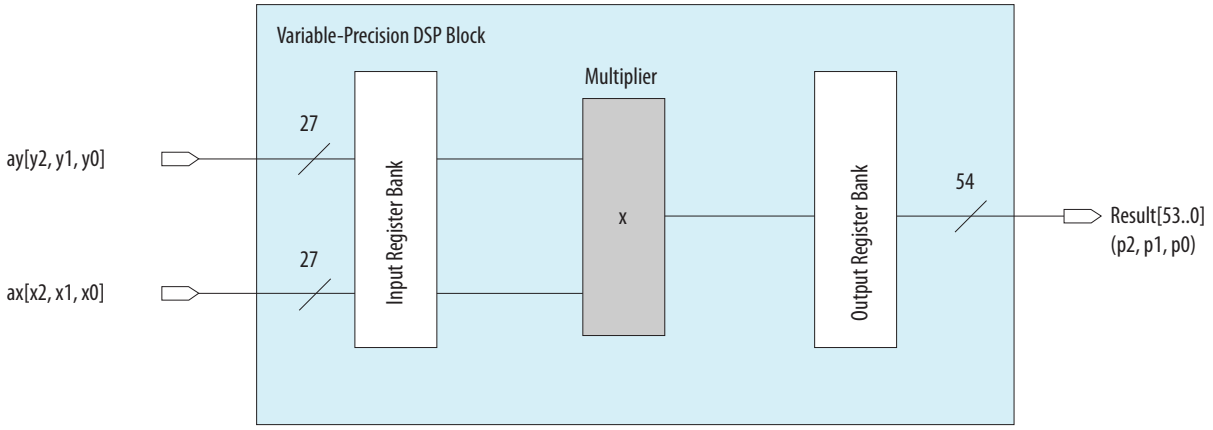
Table 3-7: Independent Multiplier Mode Configurations with Multiple Variable Precision DSP Blocks for Arria V Devices

Configuration	Number of DSP Blocks Required	Device Variant Support
3 independent 18 x 18 multipliers	2	Arria V GZ
36 x 36 multiplier	2	Arria V GZ

9 x 9 Independent Multiplier

Figure 3-9: Three 9 x 9 Independent Multiplier Mode per Variable Precision DSP Block for Arria V Devices

Three pairs of data are packed into the ax and ay ports; `result` contains three 18-bit products.



18 x 18 Independent Multiplier

Figure 3-10: One 18 x 18 Independent Multiplier Mode with One Variable Precision DSP Block for Arria V GZ Devices

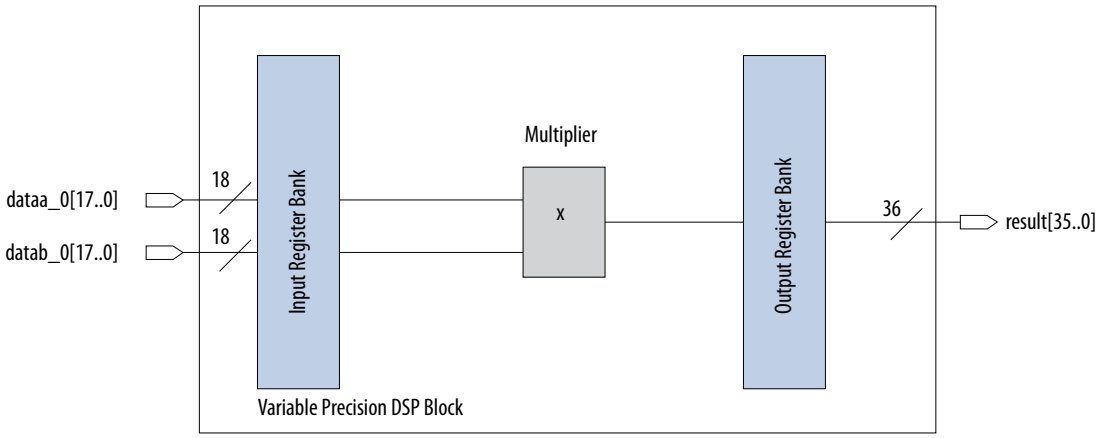


Figure 3-11: Three 18 x 18 Independent Multiplier Mode with Two Variable Precision DSP Blocks for Arria V GZ Devices

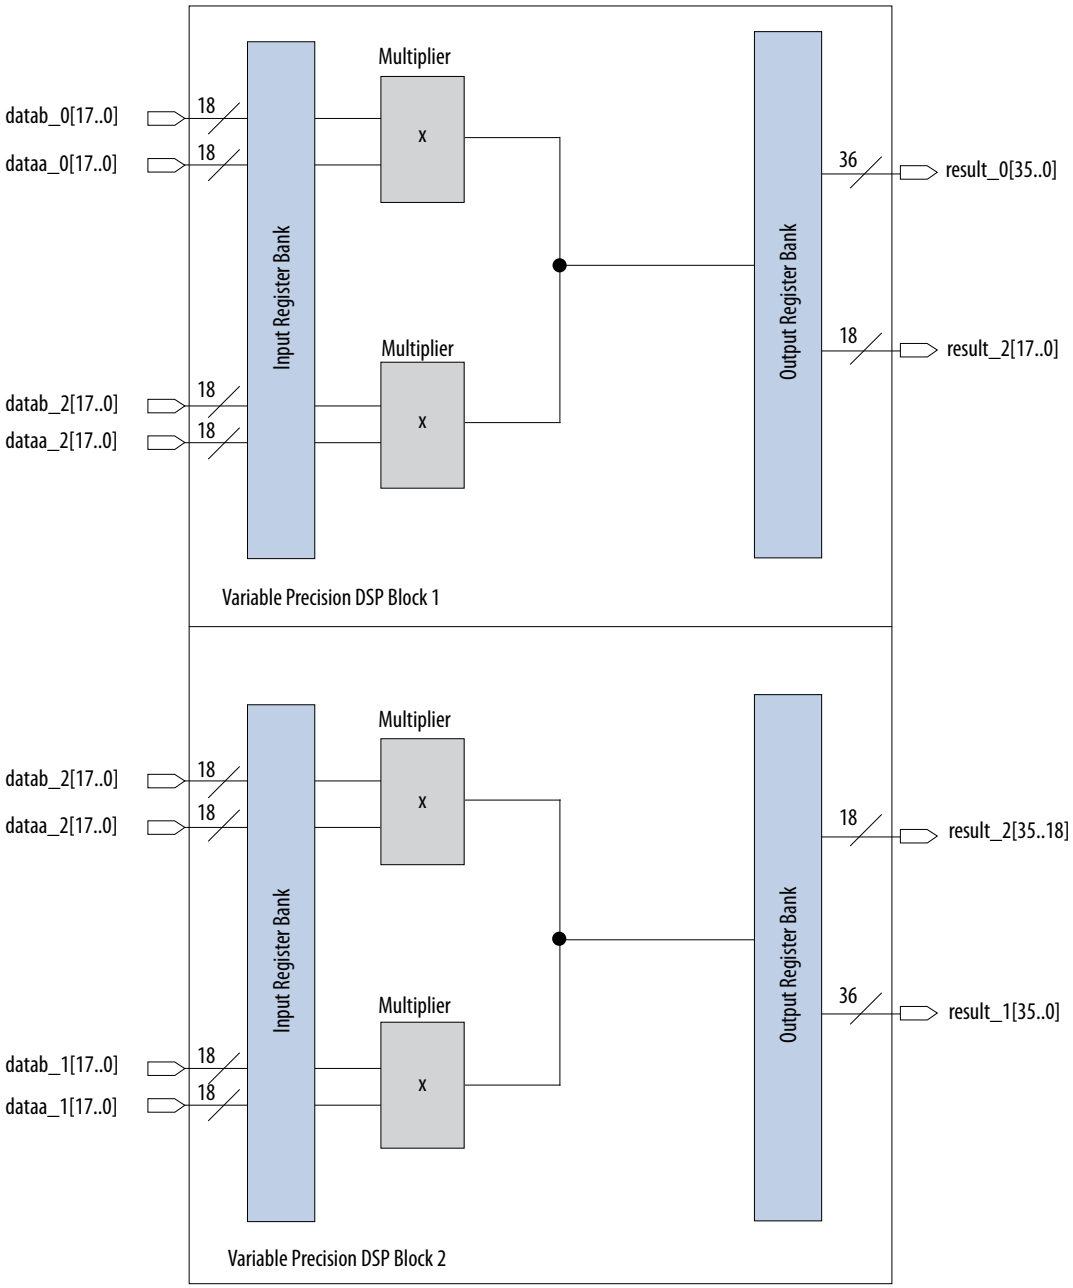
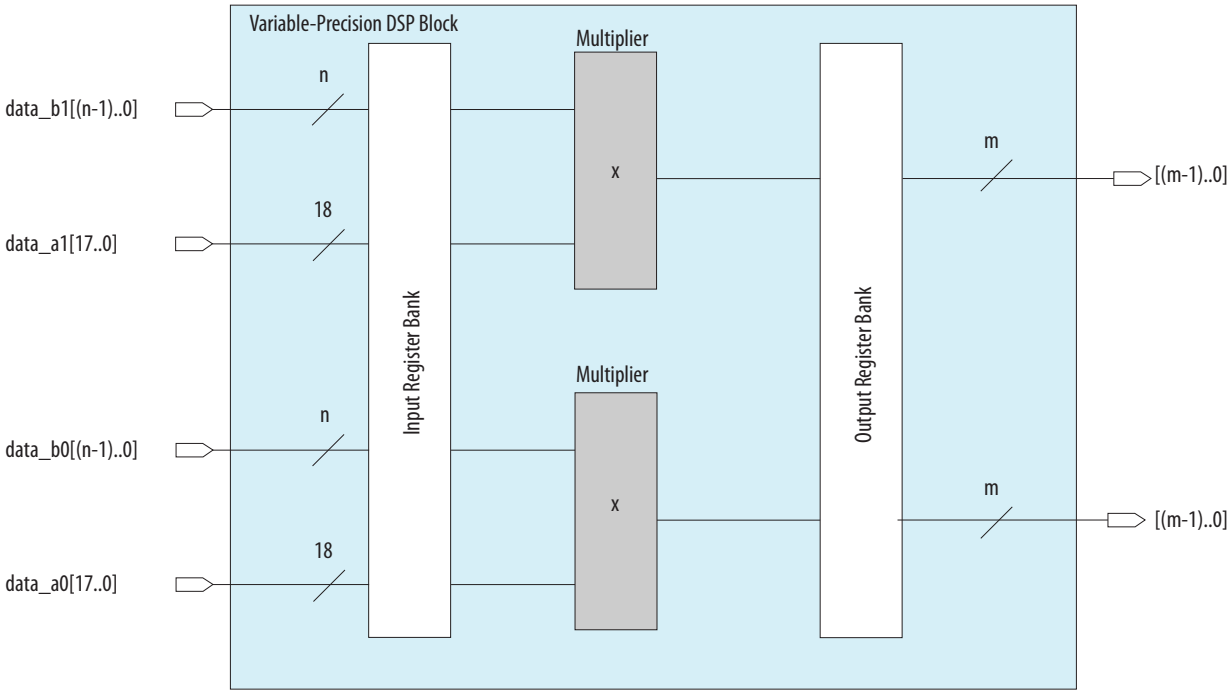


18 x 18 or 18 x 19 Independent Multiplier

Figure 3-12: Two 18 x 18 or 18 x 19 Independent Multiplier Mode per Variable Precision DSP Block for Arria V GX, GT, SX, and ST Devices

In this figure, the variables are defined as follows:

- n = 19 and m = 37 for 18 x 19 mode
- n = 18 and m = 36 for 18 x 18 mode

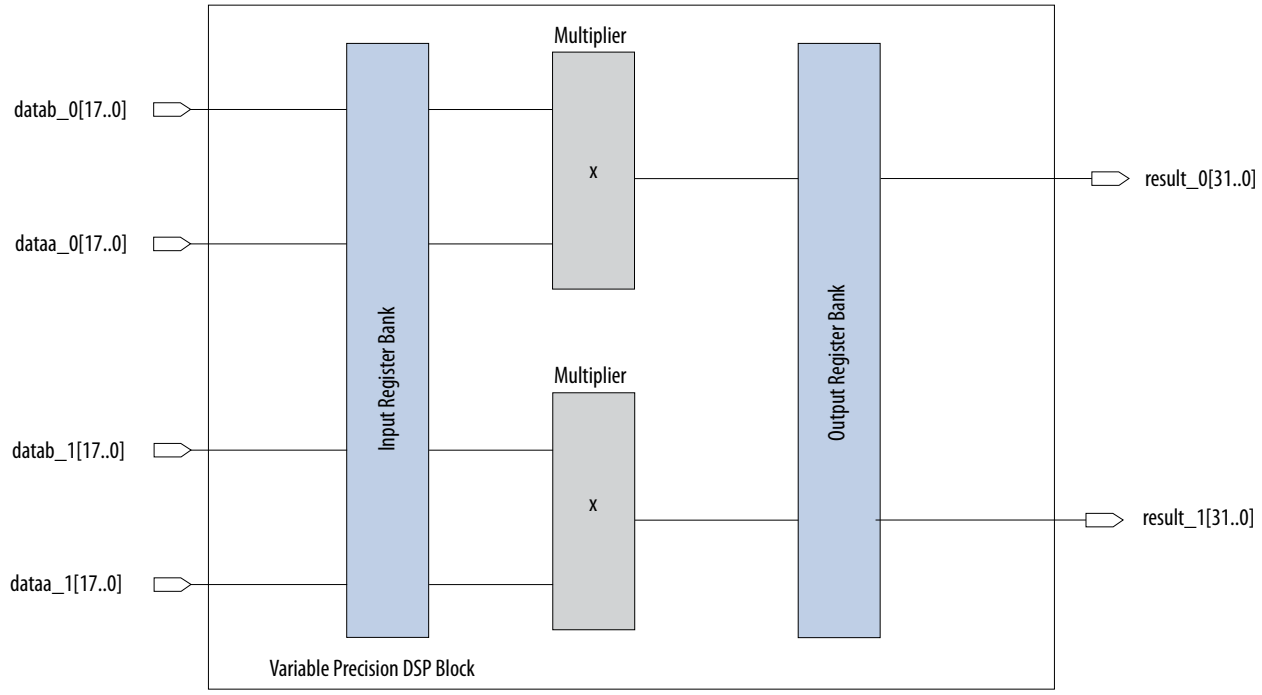


16 x 16 Independent Multiplier or 18 x 18 Independent Partial Multiplier

Figure 3-13: Two 16 x 16 Independent Multiplier Mode or Two 18 x 18 Independent Partial Multiplier Mode for Arria V GZ Devices

In this figure, the inputs for 16-bit independent multiplier mode are `data[15..0]`. The unused input bits require padding with zero.

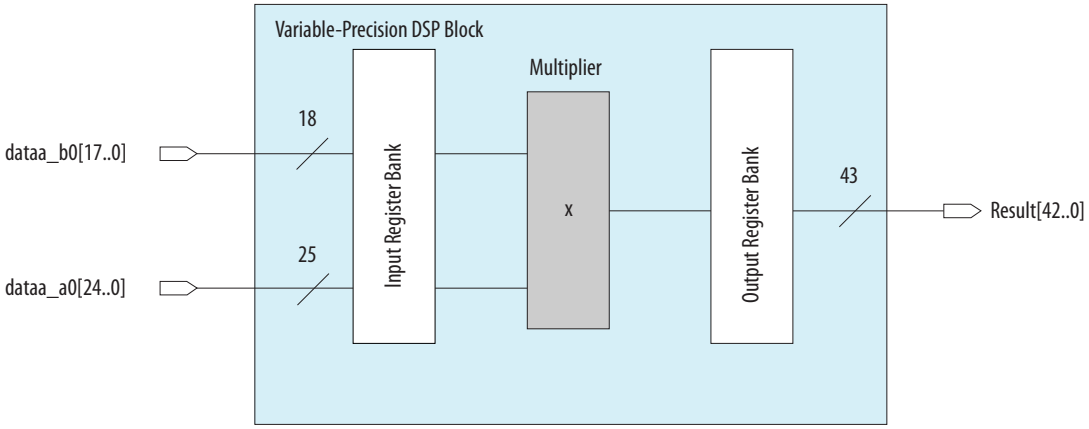
For two independent 18 x 18 partial multiplier mode, only 32-bit LSB result for each multiplication operation is routed to the output. The output has full precision if the total width of the multiplicand input is less than or equal to 32 bits for each multiplier.



18 x 25 Independent Multiplier

Figure 3-14: One 18 x 25 Independent Multiplier Mode per Variable Precision DSP Block for Arria V GX, GT, SX, and ST Devices

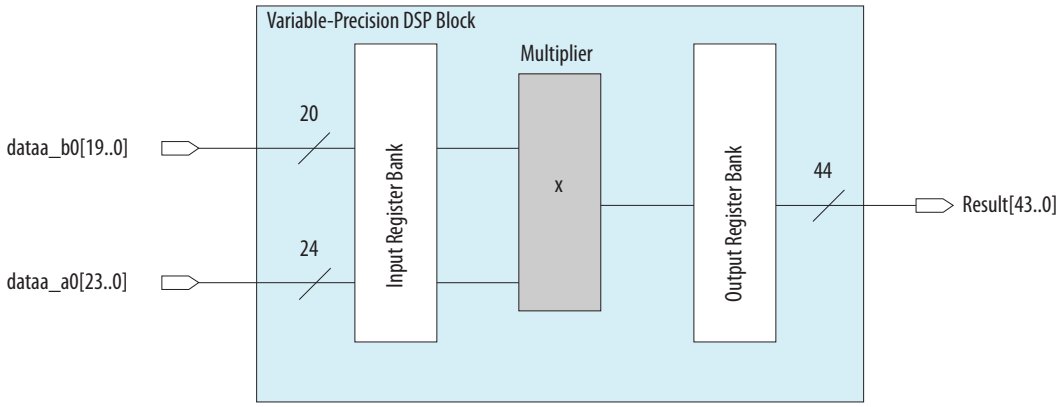
In this mode, the `result` can be up to 52 bits when combined with a chainout adder or accumulator.



20 x 24 Independent Multiplier

Figure 3-15: One 20 x 24 Independent Multiplier Mode per Variable Precision DSP Block for Arria V GX, GT, SX, and ST Devices

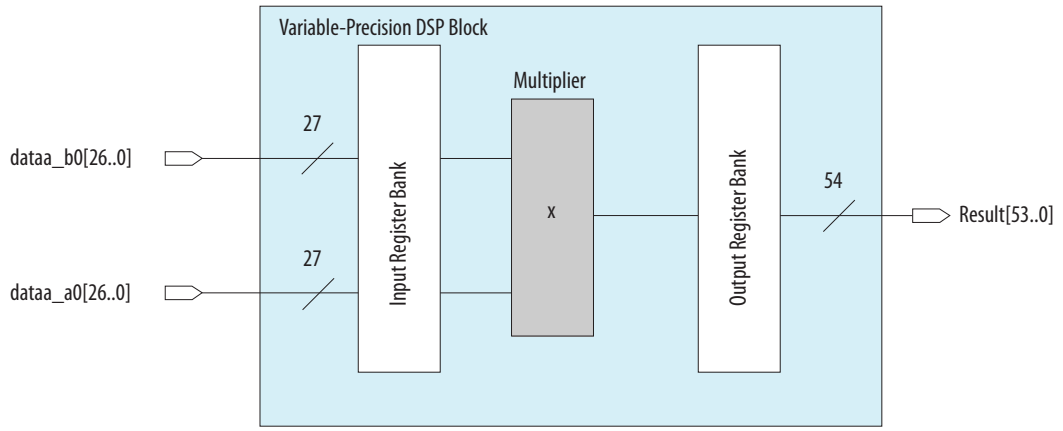
In this mode, the `result` can be up to 52 bits when combined with a chainout adder or accumulator.



27 x 27 Independent Multiplier

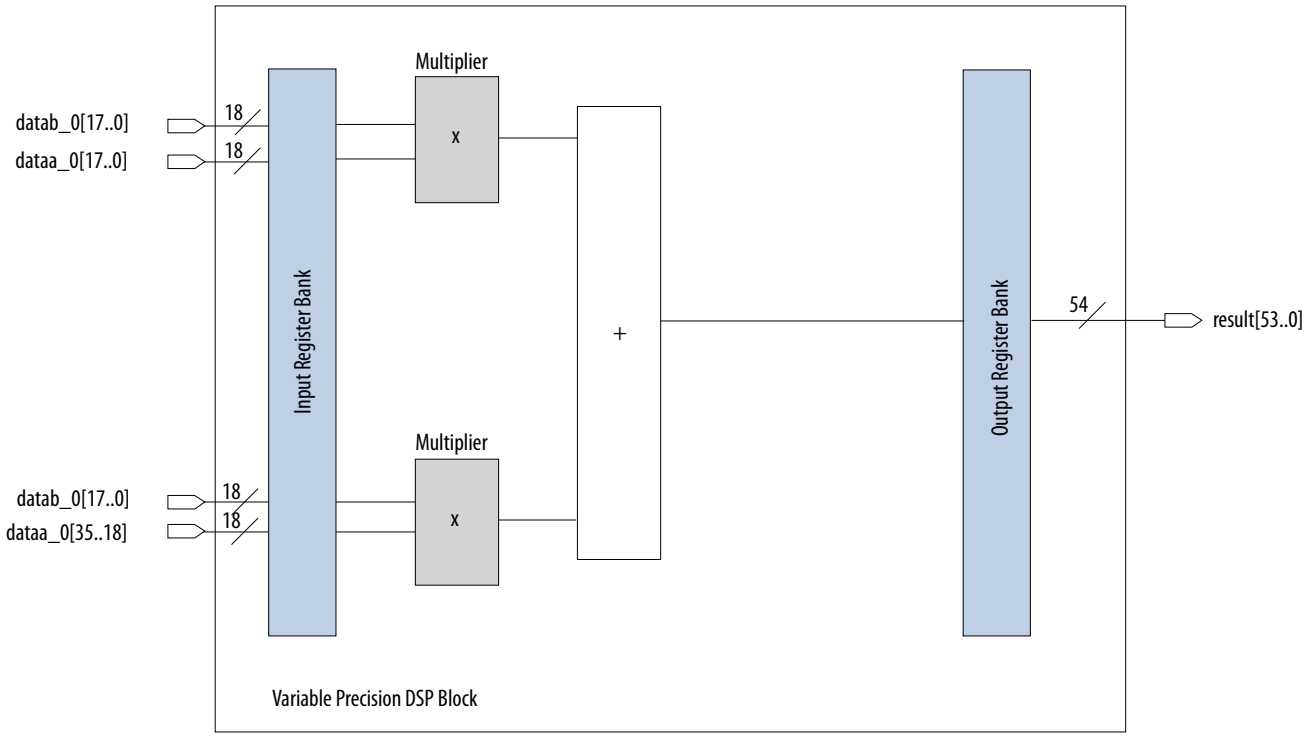
Figure 3-16: One 27 x 27 Independent Multiplier Mode per Variable Precision DSP Block for Arria V Devices

In this mode, the `result` can be up to 64 bits when combined with a chainout adder or accumulator.



36 x 18 Independent Multiplier

Figure 3-17: One 36 x 18 Independent Multiplier Mode for Arria V GZ Devices

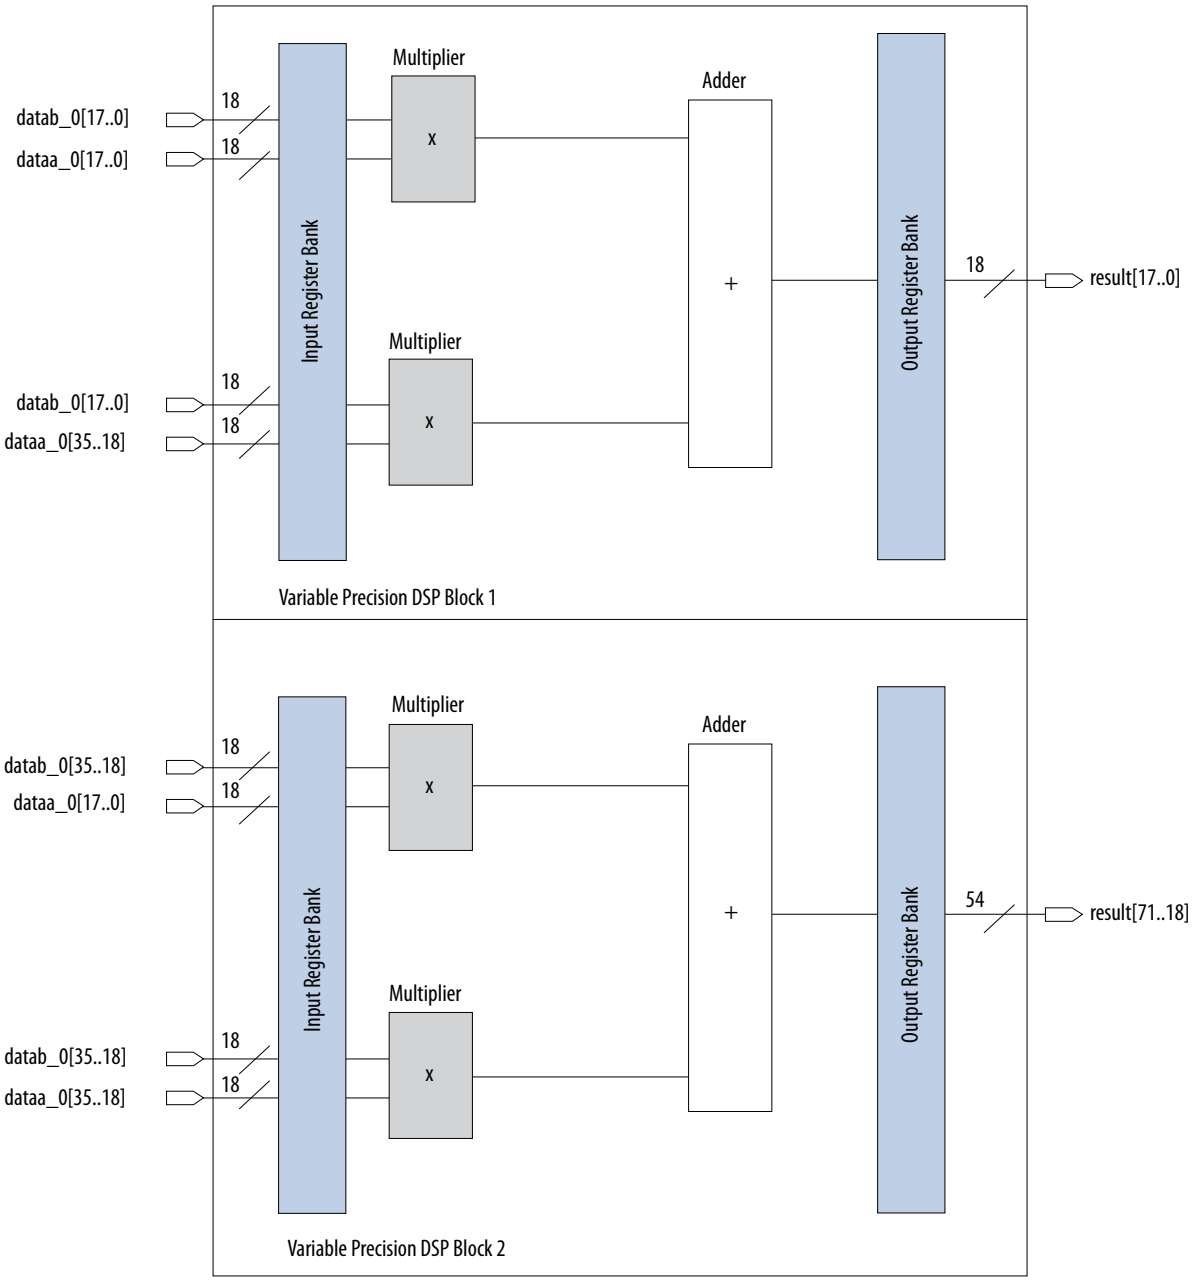


36-Bit Independent Multiplier

You can efficiently construct an individual 36-bit multiplier with two adjacent variable precision DSP blocks. The 36 x 36 multiplication consists of four 18 x 18 multipliers.

The 36-bit multiplier is useful for applications requiring more than 18-bit precision; for example, for the mantissa multiplication portion of very high precision fixed-point arithmetic applications.

Figure 3-18: 36-Bit Independent Multiplier Mode with Two Variable Precision DSP Blocks for Arria V GZ Devices



Independent Complex Multiplier Mode

The Arria V variable precision DSP block provides the means for a complex multiplication.

Figure 3-19: Sample of Complex Multiplication Equation

$$(a + jb) \times (c + jd) = [(a \times c) - (b \times d)] + j[(a \times d) + (b \times c)]$$

Table 3-8: Variable Precision DSP Block Independent Complex Multiplier Mode Configurations for Arria V Devices

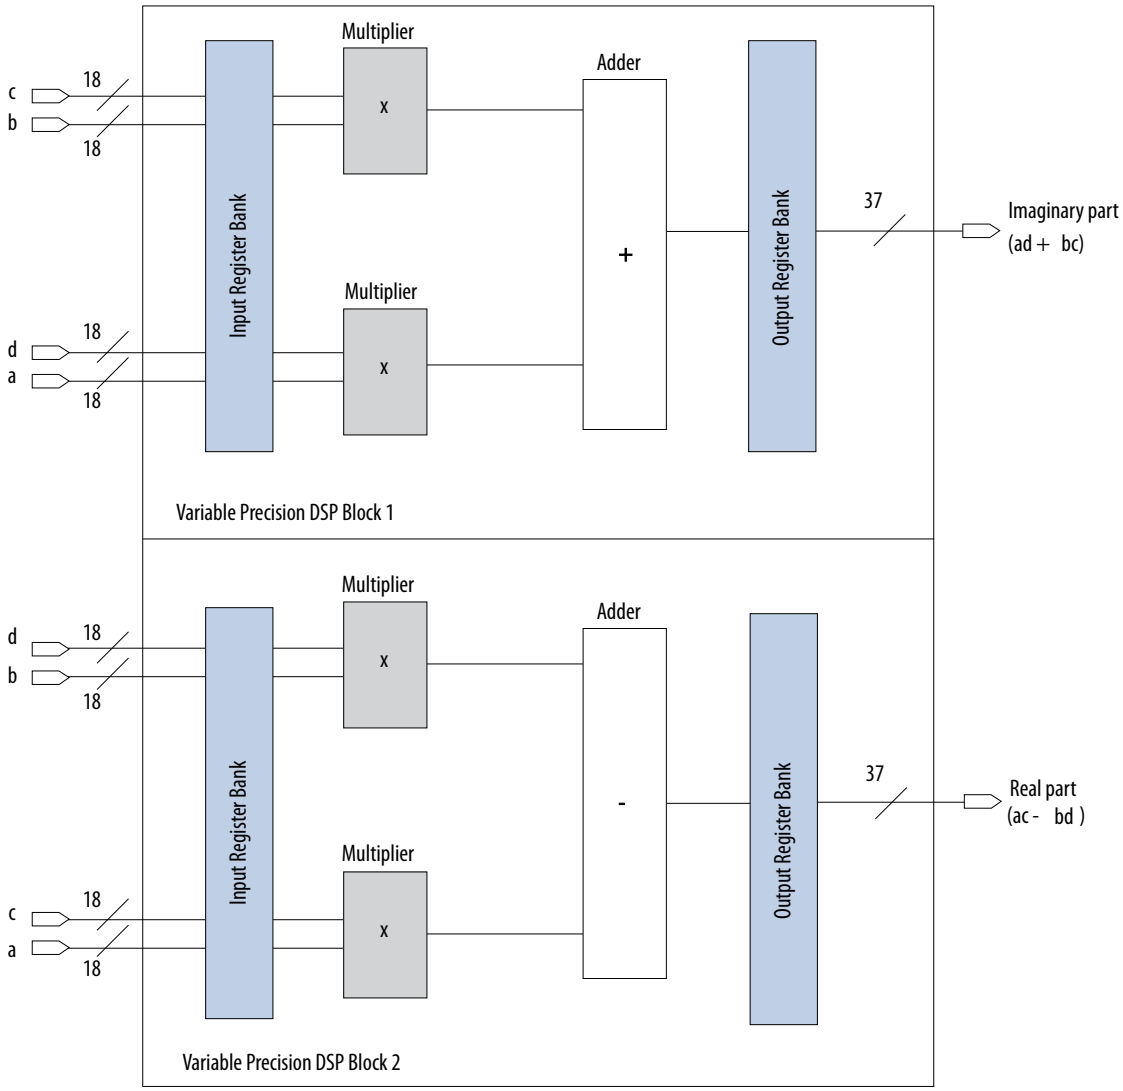
Configuration	Number of DSP Blocks Required	Device Variant Support
18 x 18	2	Arria V GZ
18 x 19	2	Arria V GX, GT, SX, ST
18 x 25	3	Arria V GZ
27 x 27	4	Arria V GZ

18 x 18 Complex Multiplier

For 18 x 18 complex multiplication mode, you require two variable precision DSP blocks to perform this multiplication.

You can implement the imaginary part [(a × d) + (b × c)] in the first variable precision DSP block, and you can implement the real part [(a × c) – (b × d)] in the second variable precision DSP block.

Figure 3-20: 18 x 18 Complex Multiplier with Two Variable Precision DSP Blocks for Arria V GZ Devices

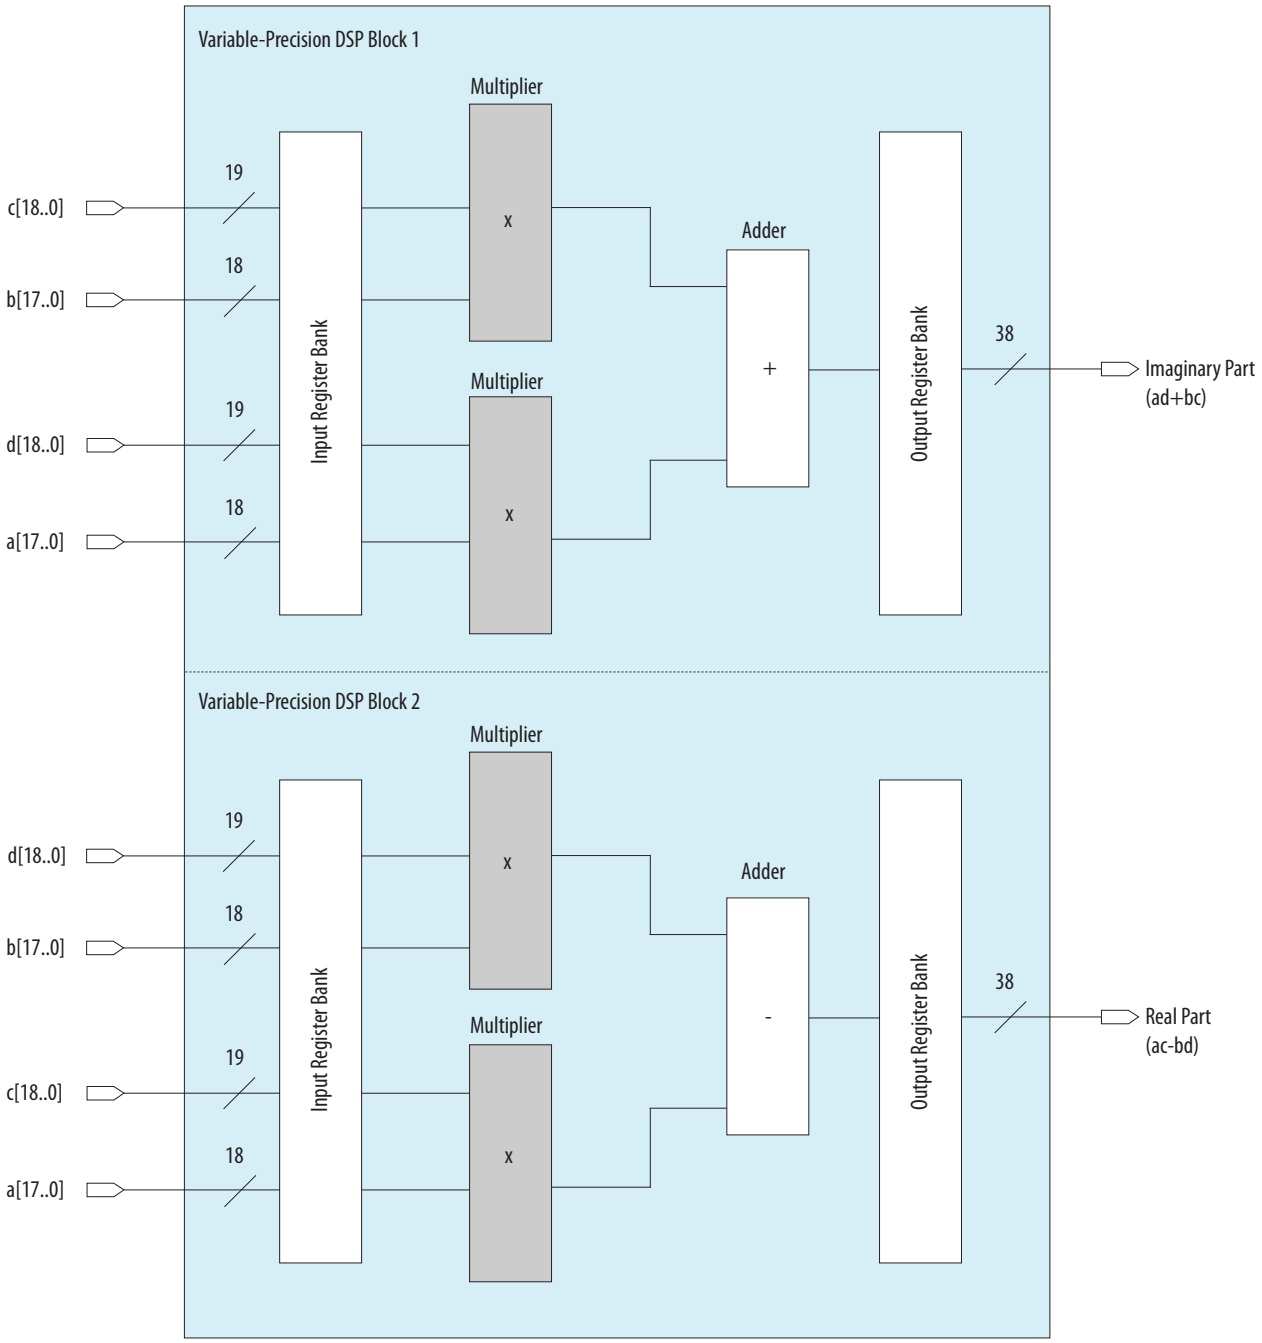


18 x 19 Complex Multiplier

For 18 x 19 complex multiplication mode, you require two variable precision DSP blocks to perform this multiplication.

The imaginary part [(a × d) + (b × c)] is implemented in the first variable precision DSP block, while the real part [(a × c) - (b × d)] is implemented in the second variable precision DSP block.

Figure 3-21: One 18 x 19 Complex Multiplier with Two Variable Precision DSP Blocks for Arria V GX, GT, SX, and ST Devices



18 x 25 Complex Multiplier

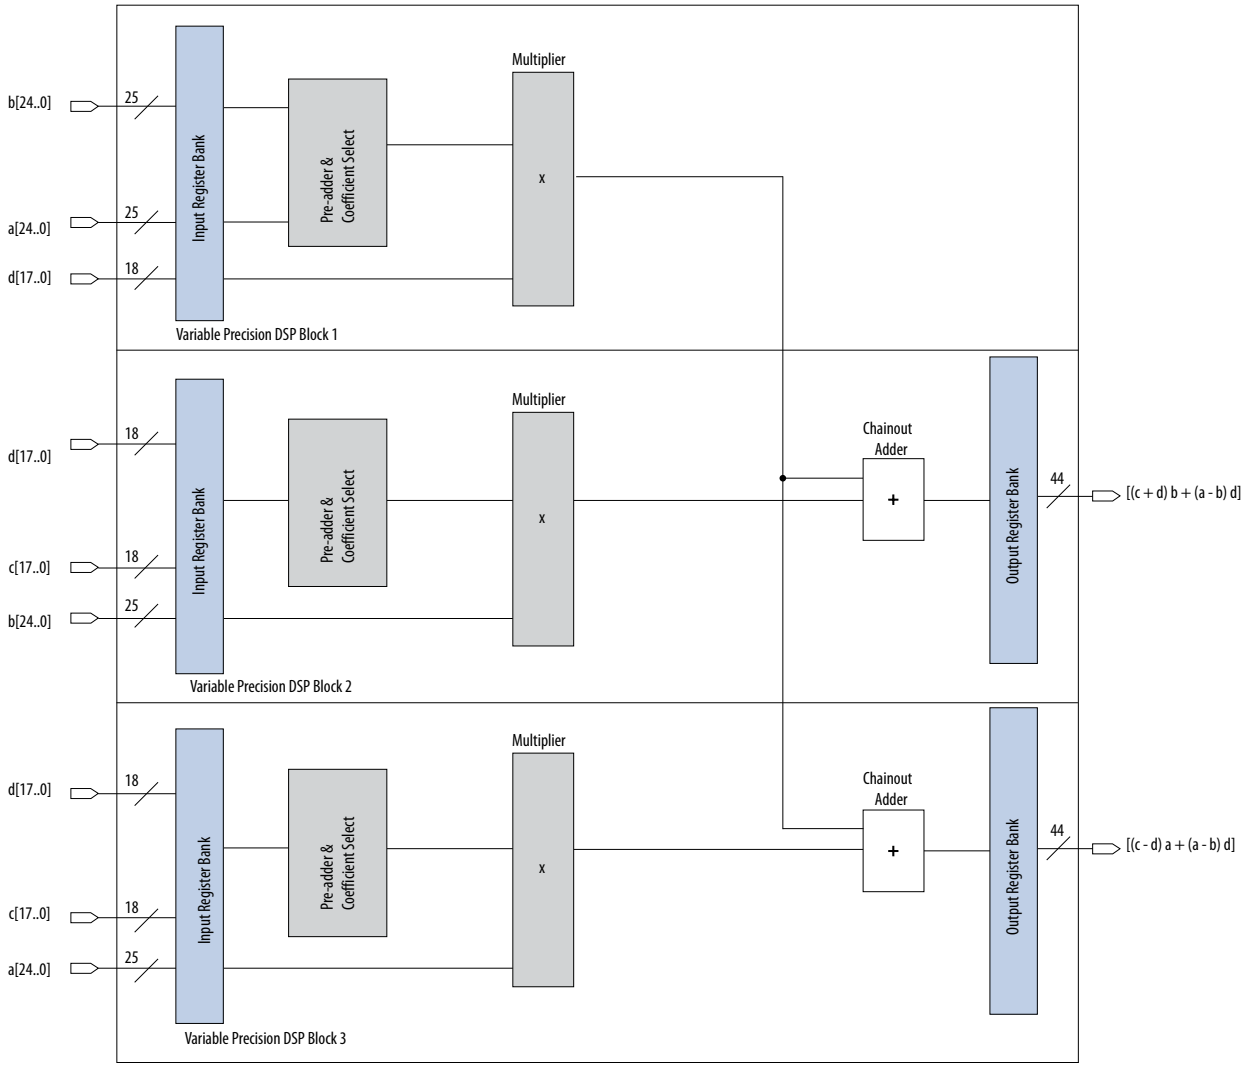
Arria V GZ devices support an individual 18 x 25 complex multiplication mode.

A 27 x 27 multiplier allows you to implement an individual 18 x 25 complex multiplication mode with three variable precision DSP blocks only. The pre-adder feature is automatically enabled for you to implement an individual 18 x 25 complex multiplication mode efficiently.

Figure 3-22: 18 x 25 Complex Multiplication Equation

$$(a + jb) \times (c + jd) = (c - d) \times a + (a - b) \times d + j[(c + d) \times b + (a - b) \times d]$$

Figure 3-23: 18 x 25 Complex Multiplier with Three Variable Precision DSP Blocks for Arria V GZ Devices



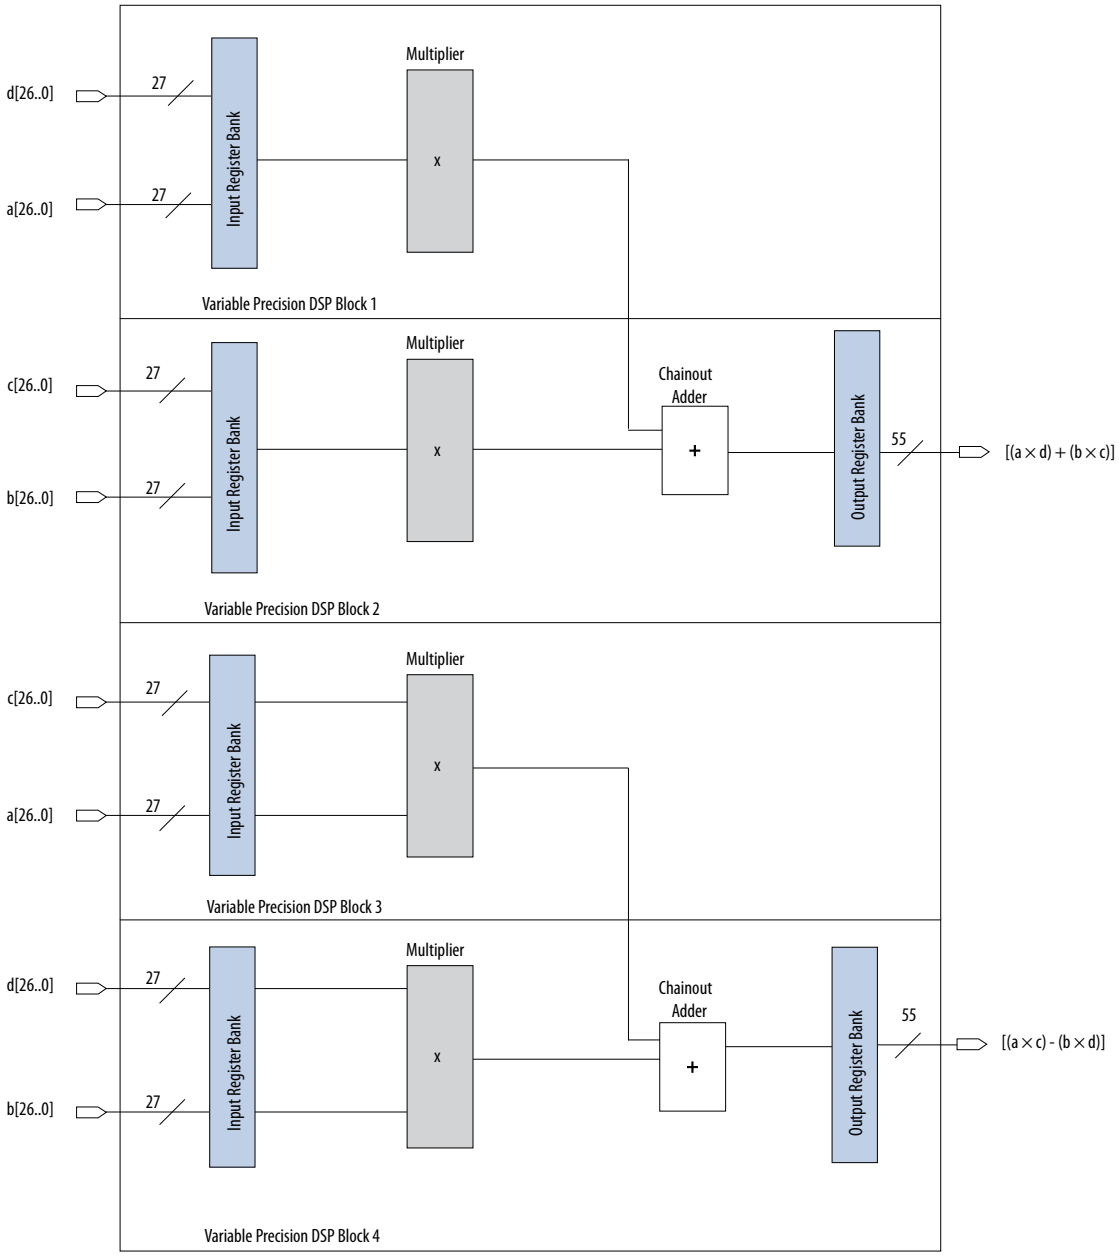
27 x 27 Complex Multiplier

Arria V GZ devices support an individual 27 x 27 complex multiplication mode. You require four variable precision DSP blocks to implement an individual 27 x 27 complex multiplication mode.

You can implement the imaginary part [(a x d) + (b x c)] in the first and second variable precision DSP blocks, and you can implement the real part [(a x c) - (b x d)] in the third and fourth variable precision DSP blocks.

You can achieve the difference of two 27 x 27 multiplications by enabling the NEGATE control signal in the fourth variable precision DSP block.

Figure 3-24: 27 x 27 Complex Multiplier with Four Variable Precision Blocks for Arria V GZ Devices



Multiplier Adder Sum Mode

Table 3-9: Variable Precision DSP Block Multiplier Adder Sum Mode Configurations for Arria V Devices

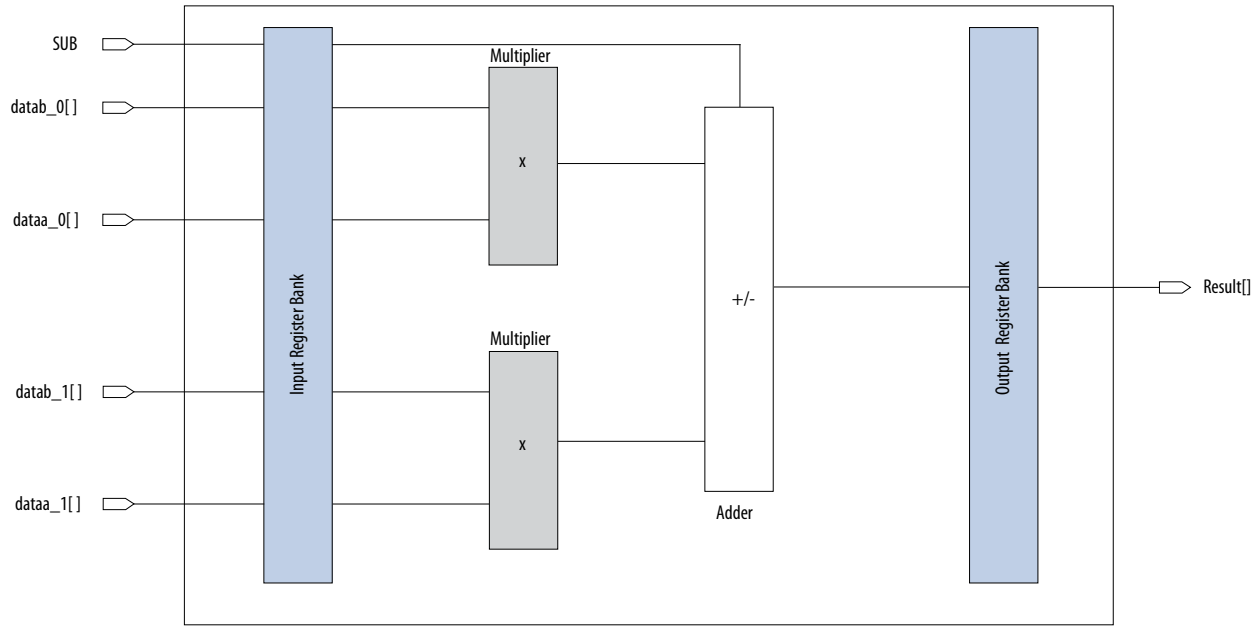
Mode	Configuration	Number of DSP Blocks Required	Device Variant Support
Two-multiplier Adder Sum	16 x 16	1	Arria V GZ
	18 x 18	1	Arria V GZ
	18 x 19	1	Arria V GX, GT, SX, ST
	27 x 27	2	Arria V GZ
	36 x 18	2	Arria V GZ
Four-multiplier Adder Sum	18 x 18	2	Arria V GZ

One Sum of Two 18 x 18 Multipliers or Two 16 x 16 Multipliers

Figure 3-25: One Sum of Two 18 x 18 Multipliers or Two 16 x 16 Multipliers with One Variable Precision DSP Block for Arria V GZ Devices

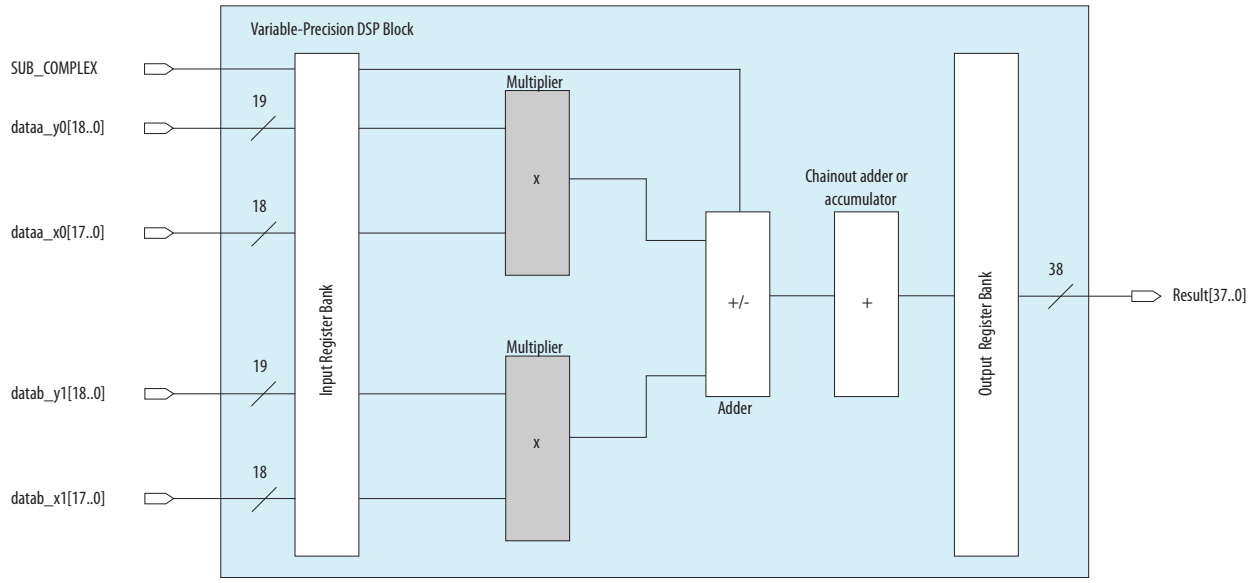
In this figure, for 18-bit multiplier adder sum mode, the input data width is 18 bits and the output data width is 37 bits.

For 16-bit multiplier adder sum mode, the input data width is 16 bits and the unused input bit requires padding with zeroes. The output data width is 33 bits.



One Sum of Two 18 x 19 Multipliers

Figure 3-26: One Sum of Two 18 x 19 Multipliers with One Variable Precision DSP Block for Arria V GX, GT, SX, and ST Devices



One Sum of Two 27 x 27 Multipliers

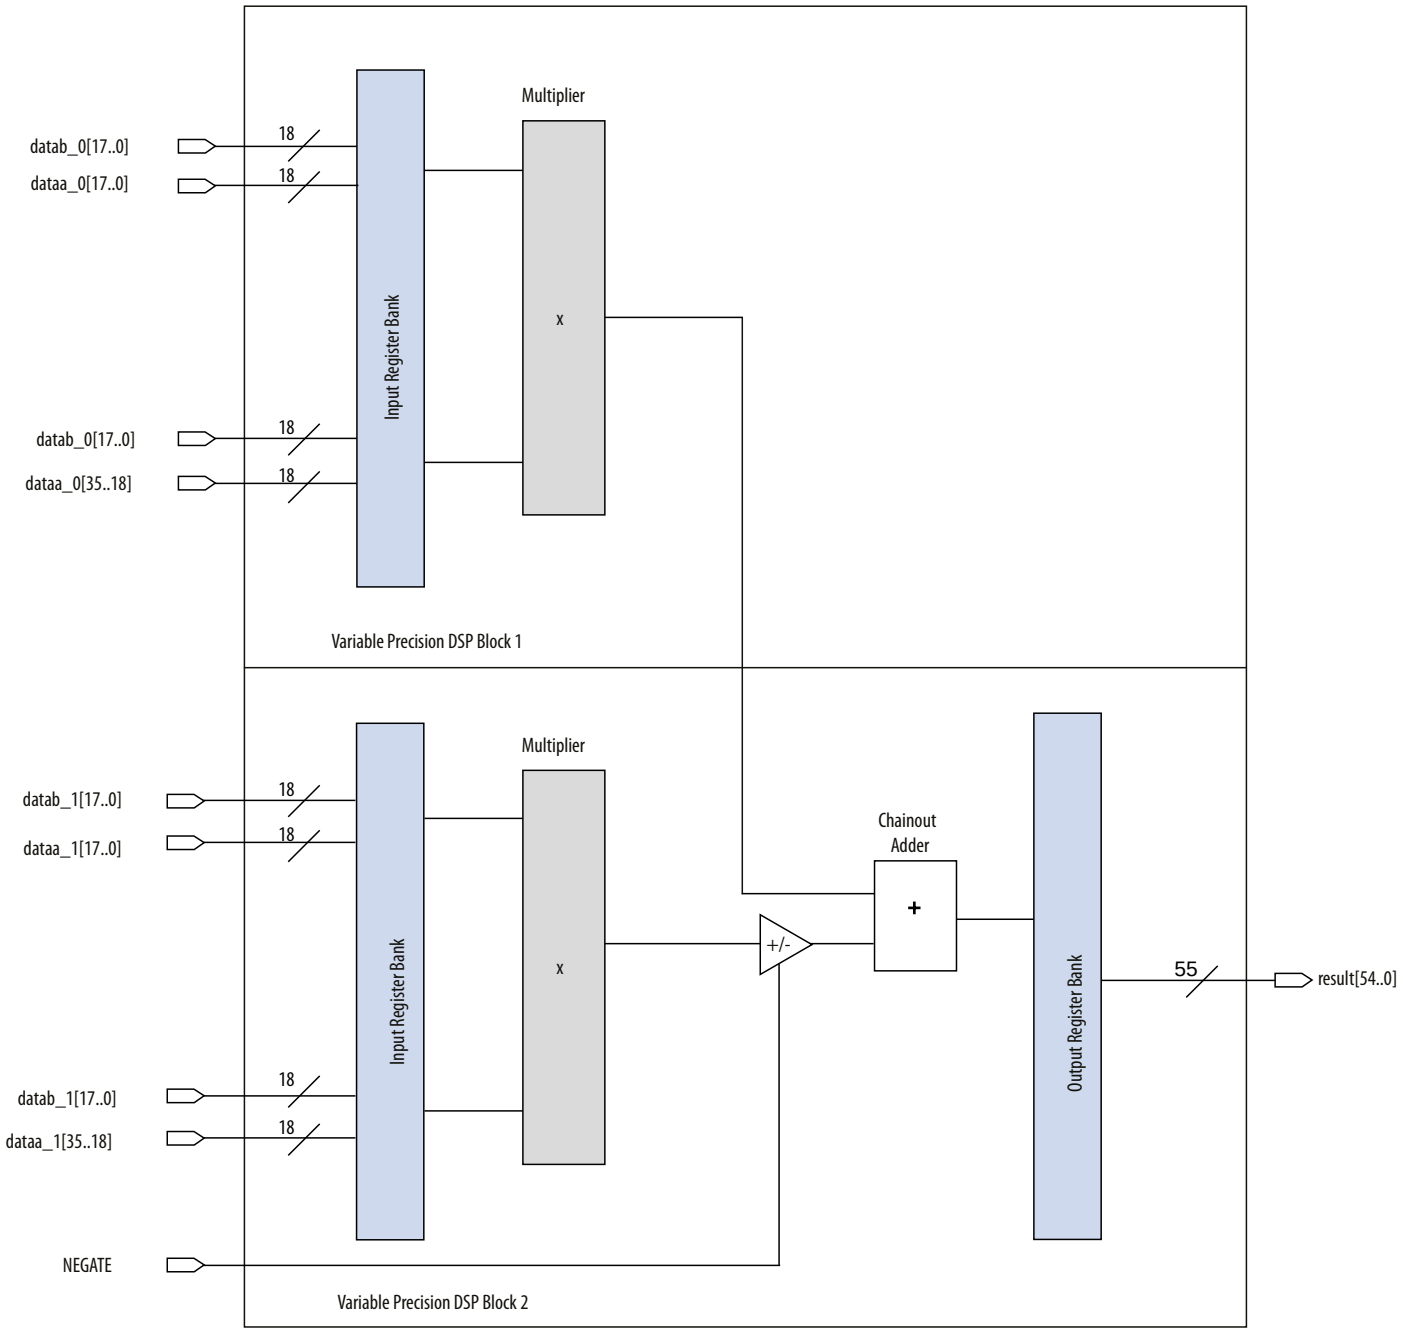
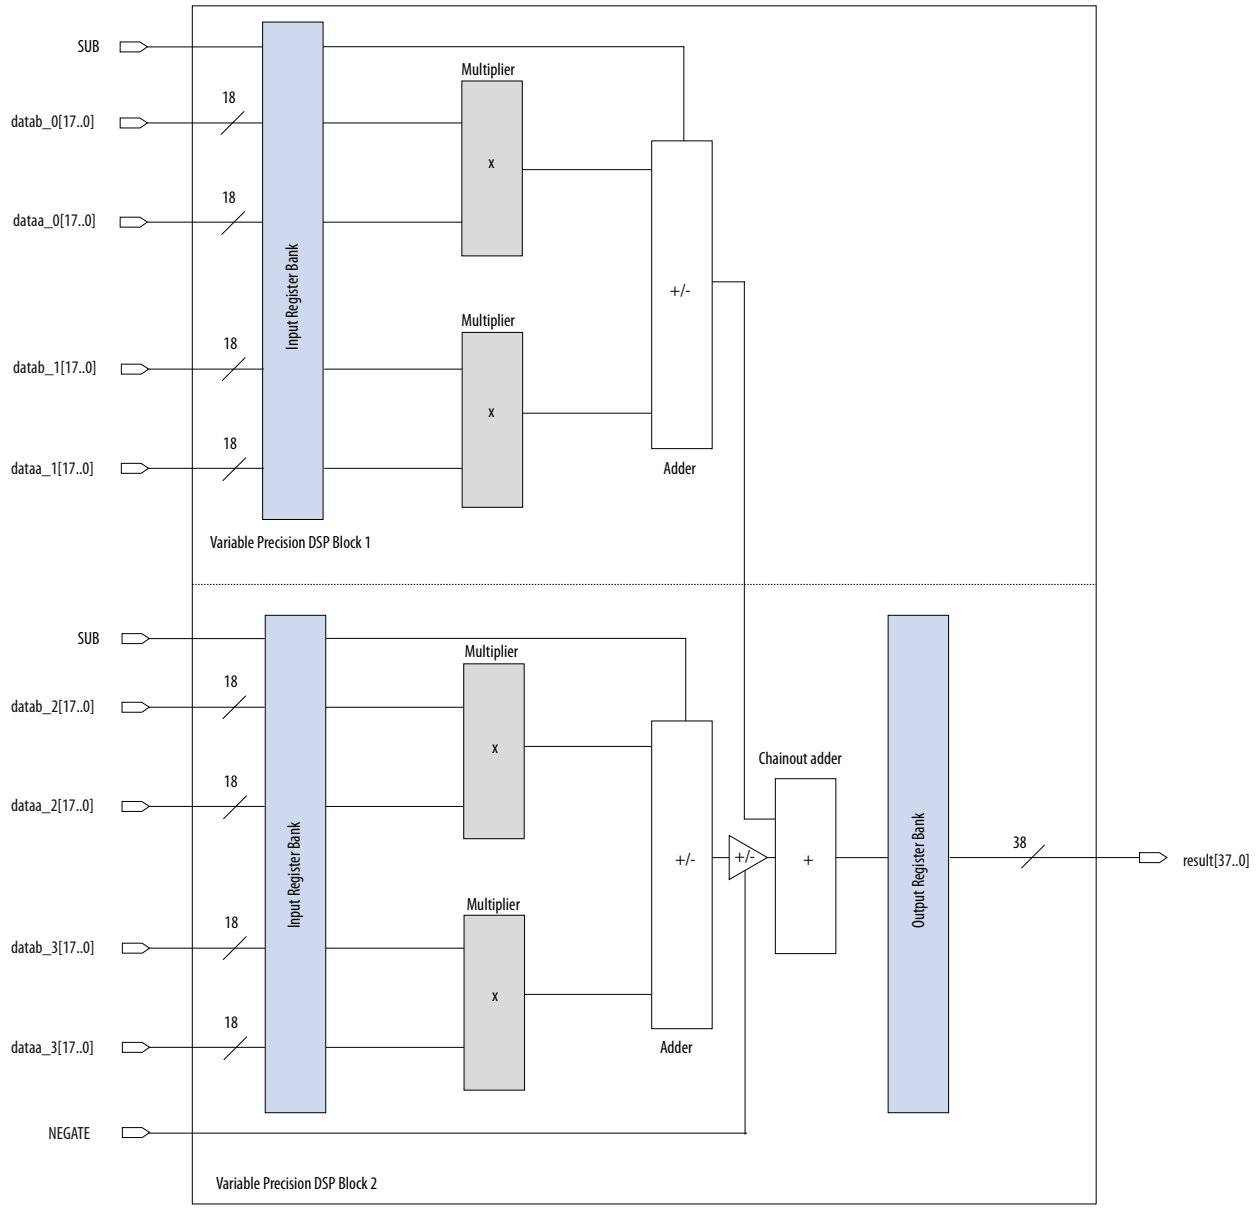
One Sum of Two 36 x 18 Multipliers

Figure 3-28: One Sum of Two 36 x 18 Multipliers with Two Variable Precision DSP Blocks for Arria V GZ Devices



One Sum of Four 18 x 18 Multipliers

Figure 3-29: One Sum of Four 18 x 18 Multipliers with Two Variable Precision DSP Blocks for Arria V GZ Devices



Sum of Square Mode

The Arria V variable precision DSP block can implement one sum of square mode.

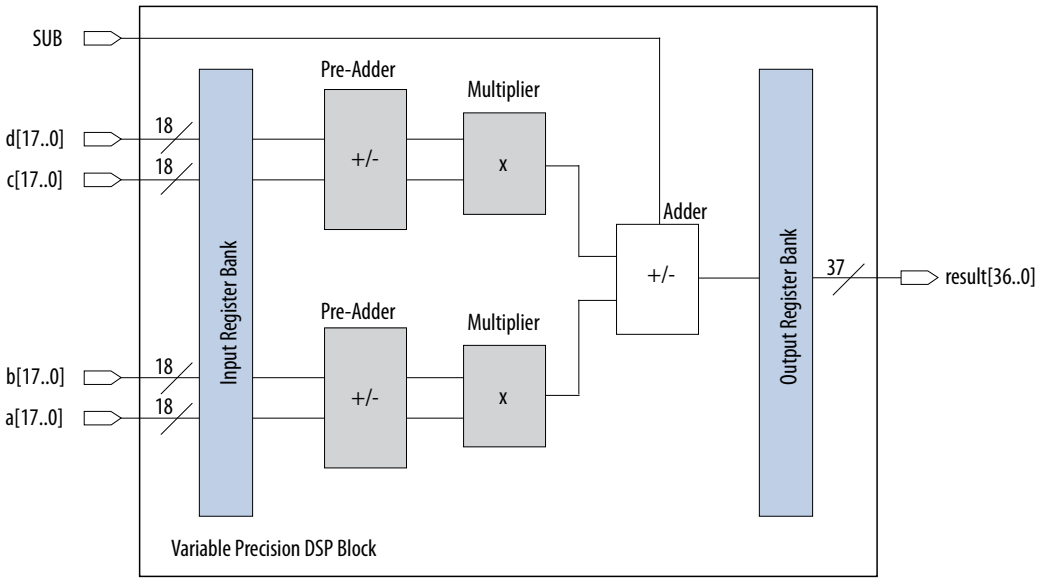
Figure 3-30: One Sum of Square Mode Equation

$$(a \pm b)^2 \times (c \pm d)^2$$

You can feed the four 18-bit inputs into the pre-adder block to convert `b` and `d` input as two's complement numbers to perform subtraction, if required.

You can feed each 18-bit pre-adder block output into both multiplicand and multiplier inputs of an 18 x 18 multiplier to generate a square result.

Figure 3-31: One Sum of Square Mode in a Variable Precision DSP Block for Arria V GZ Devices



18 x 18 Multiplication Summed with 36-Bit Input Mode

Arria V variable precision DSP blocks support one 18 x 18 multiplication summed to a 36-bit input.

Use the upper multiplier to provide the input for an 18 x 18 multiplication, while the bottom multiplier is bypassed.

The following signals are concatenated to produce a 36-bit input:

- Arria V GX, GT, SX, and ST devices: `datab_y1[17..0]` and `datab_y1[35..18]`
- Arria V GZ devices: `data1[17..0]` and `data1[35..18]`

Figure 3-32: One 18 x 18 Multiplication Summed with 36-Bit Input Mode for Arria V GX, GT, SX, and ST Devices

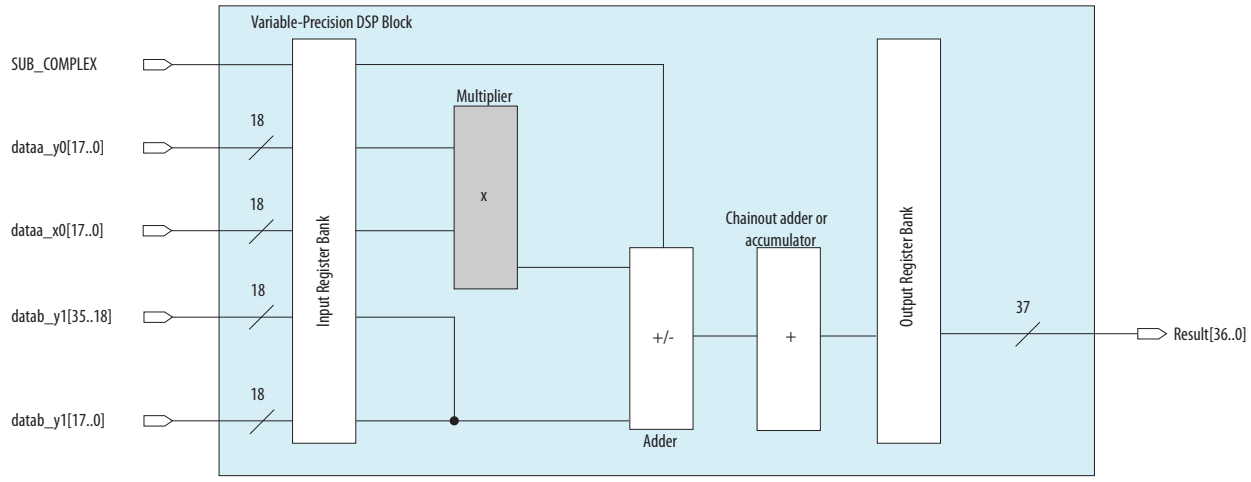


Figure 3-33: One 18 x 18 Multiplication Summed with 36-Bit Input Mode for Arria V GZ Devices

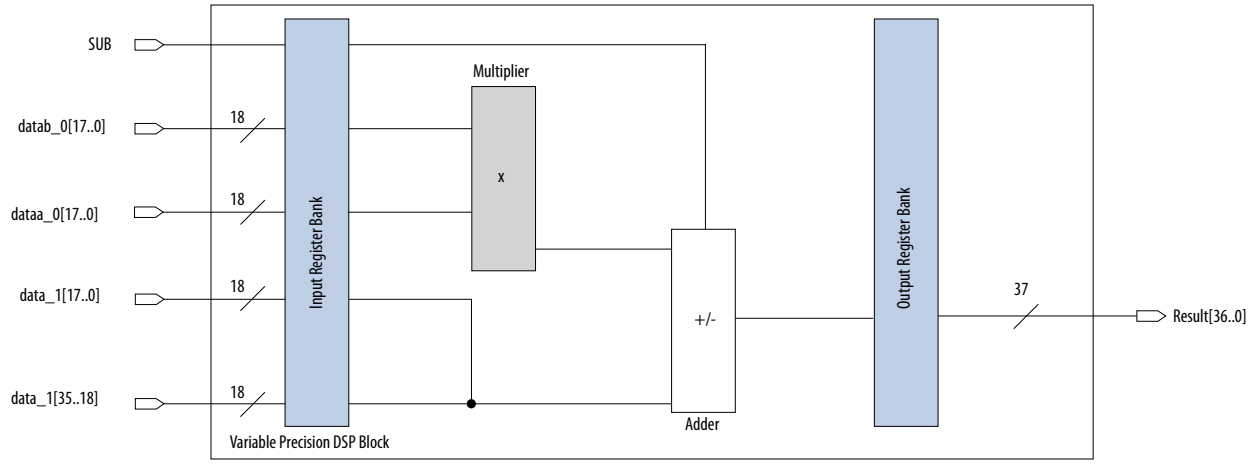


Systolic FIR Mode

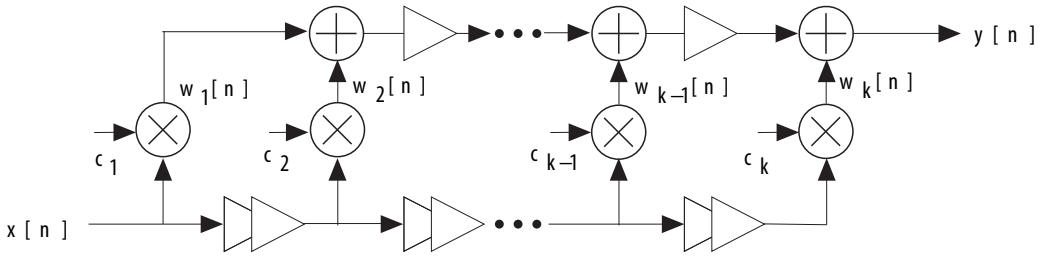
The basic structure of a FIR filter consists of a series of multiplications followed by an addition.

Figure 3-34: Basic FIR Filter Equation

$$y[n] = \sum_{i=1}^{k} c[i]x[n-i-1]$$

Depending on the number of taps and the input sizes, the delay through chaining a high number of adders can become quite large. To overcome the delay performance issue, the systolic form is used with additional delay elements placed per tap to increase the performance at the cost of increased latency.

Figure 3-35: Systolic FIR Filter Equivalent Circuit



Arria V variable precision DSP blocks support the following systolic FIR structures:

- 18-bit
- 27-bit

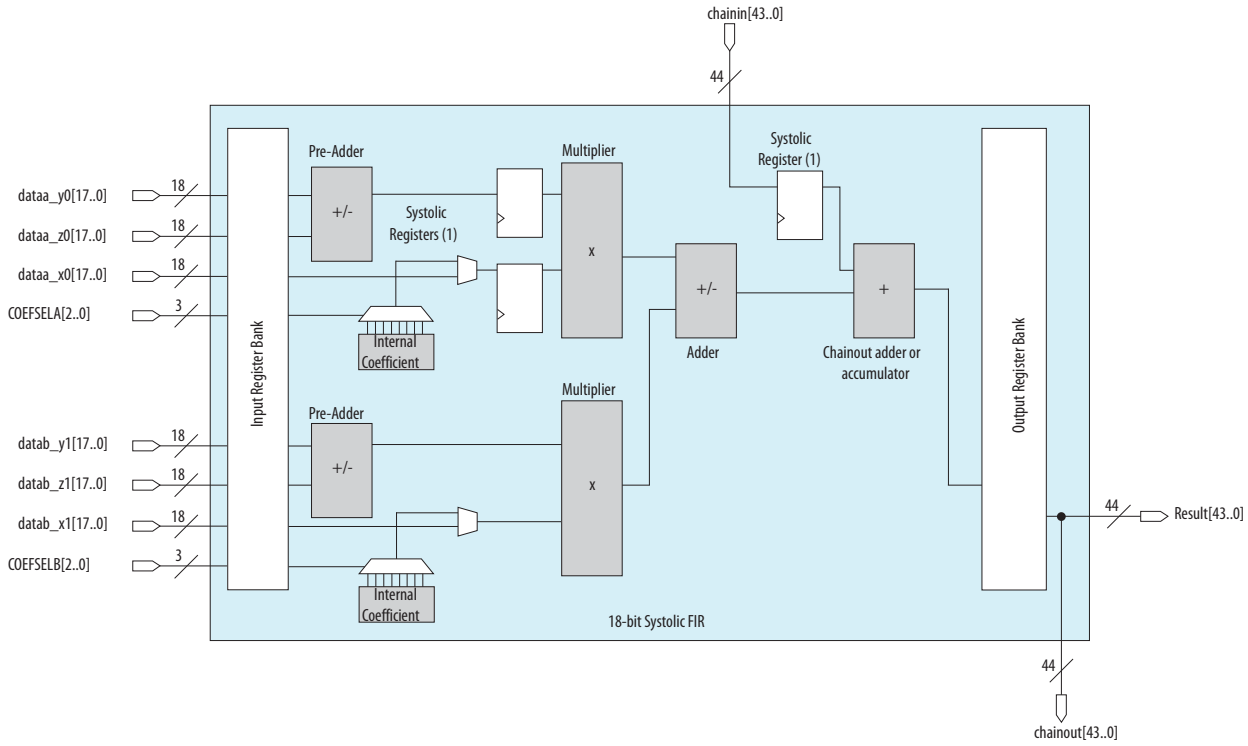
In systolic FIR mode, the input of the multiplier can come from four different sets of sources:

- Two dynamic inputs
- One dynamic input and one coefficient input
- One coefficient input and one pre-adder output
- One dynamic input and one pre-adder output (for Arria V GX, GT, SX, and ST devices only)

18-Bit Systolic FIR Mode

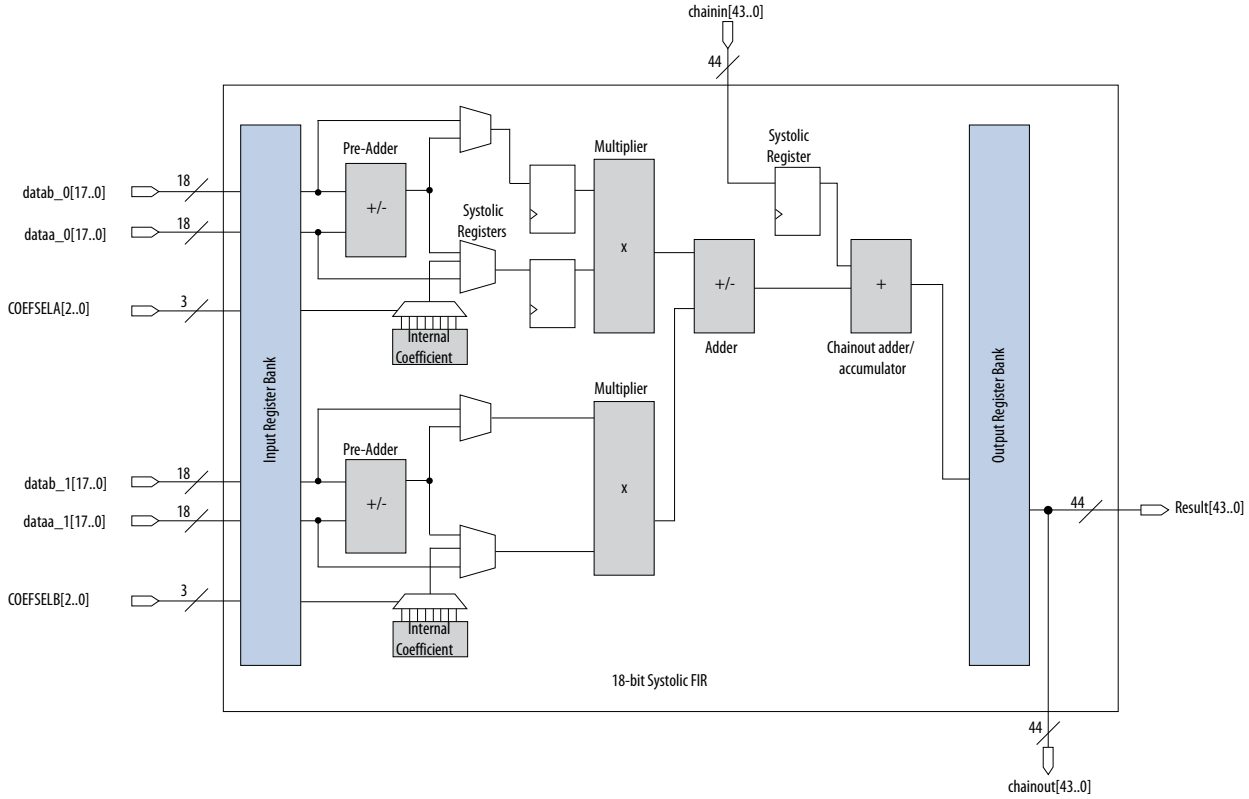
In 18-bit systolic FIR mode, the adders are configured as dual 44-bit adders, thereby giving 8 bits of overhead when using an 18-bit operation (36-bit products). This allows a total of 256 multiplier products.

Figure 3-36: 18-Bit Systolic FIR Mode for Arria V GX, GT, SX, and ST Devices



Note:
1. The systolic registers have the same clock source as the output register bank.

Figure 3-37: 18-Bit Systolic FIR Mode with Two Dynamic Inputs for Arria V GZ Devices



27-Bit Systolic FIR Mode

In 27-bit systolic FIR mode, the chainout adder or accumulator is configured for a 64-bit operation, providing 10 bits of overhead when using a 27-bit data (54-bit products). This allows a total of 1,024 multiplier products.

The 27-bit systolic FIR mode allows the implementation of one stage systolic filter per DSP block.

Figure 3-38: 27-Bit Systolic FIR Mode for Arria V GX, GT, SX, and ST Devices

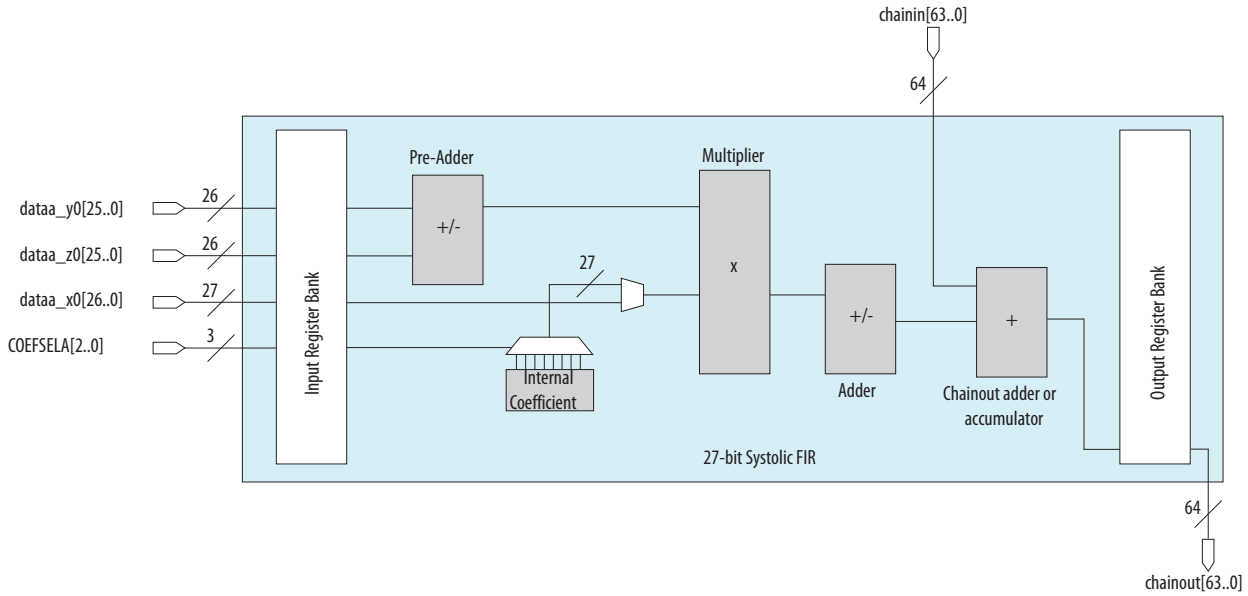


Figure 3-39: 27-Bit Systolic FIR Mode for Arria V GZ Devices

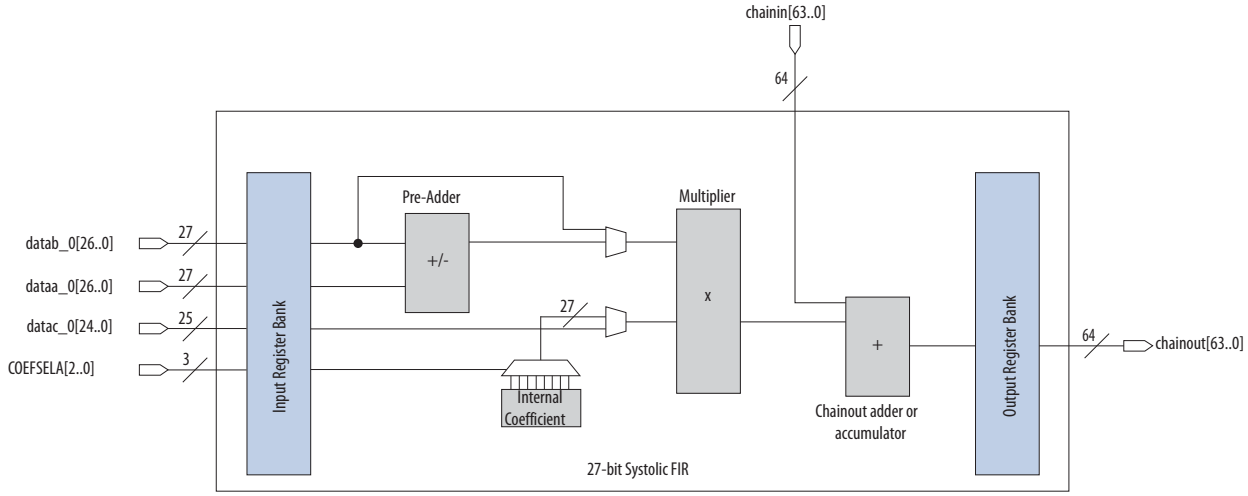

Document Revision History

Date	Version	Changes
June 2014	2014.06.30	Updated the supported megafunctions from ALTMULT_ADD and ALTMULT _ACCUM to ALTERA_MULT_ADD.

Date	Version	Changes
May 2013	2013.05.06	• Added link to the known document issues in the Knowledge Base. • Moved all links to the Related Information section of respective topics for easy reference. • Updated the variable DSP blocks and multipliers counts for the Arria V SX and ST device variants. • Updated Figure 3-21, changed 37 to 38. • Updated Figure 3-22 by changing the Complex Multiplication Equation. • Update Figure 3-26, changed 37 to 38.
November 2012	2012.11.29	• Added resources for Arria V devices. • Updated design considerations for Arria V devices in operational modes. • Added DSP block architecture in 27 x 27 mode for Arria V GX, GT, SX, and ST devices. • Added DSP block architecture in 18 x 18 and 27 x 27 modes for Arria V GZ devices. • Updated DSP block architecture information on input register bank, pre-adder, multipliers, accumulator and chainout adder, and systolic registers for Arria V GZ devices. • Added 16 x 16, 18 x 18 (partial), 18 x 18, 36 x 18, and 36-bit independent multiplier modes for Arria V GZ devices. • Added 18 x 18, 18 x 25, and 27 x 27 independent complex multiplier modes for Arria V GZ devices. • Added 16 x 16, 18 x 18, 27 x 27, and 36 x 18 multiplier adder sum modes for Arria V GZ devices. • Added sum of square mode for Arria V GZ devices. • Added 18 x 18 multiplication summed with 36-bit input mode for Arria V GZ devices. • Added 18-bit and 27-bit systolic FIR modes for Arria V GZ devices. • Reorganized content and updated template.
June 2012	2.0	Updated for the Quartus II software v12.0 release: • Restructured chapter. • Added “Design Considerations”, “Adder”, and “Double Accumulation Register” sections. • Updated Figure 3–1 and Figure 3–13. • Added Table 3–3. • Updated “Systolic Registers” and “Systolic FIR Mode” sections. • Added Equation 3–2. • Added Figure 3–12.
May 2011	1.0	Initial release.

Clock Networks and PLLs in Arria V Devices

4

2015.01.23

AV-52004 Subscribe Send Feedback

This chapter describes the advanced features of hierarchical clock networks and phase-locked loops (PLLs) in Arria V devices. The Quartus II software enables the PLLs and their features without external devices.

Clock Networks

The Arria V devices contain the following clock networks that are organized into a hierarchical structure:

- Global clock (GCLK) networks
- Regional clock (RCLK) networks
- Periphery clock (PCLK) networks

Clock Resources in Arria V Devices

Table 4-1: Clock Resources in Arria V Devices

Clock Resource	Device	Number of Resources Available	Source of Clock Resource
Clock input pins	• Arria V GX A1 and A3 • Arria V GT C3	40 single-ended or 20 differential	`CLK[0..7][p,n]` and `CLK[12..23][p,n]` pins
	• Arria V SX B3 and B5 • Arria V ST D3 and D5	40 single-ended or 20 differential	`CLK[0..11][p,n]` and `CLK[16..23][p,n]` pins
	• Arria V GX A5, A7, B1, B3, B5, and B7 • Arria V GT C7, D3, and D7 • Arria V GZ E1, E3, E5, and E7	48 single-ended or 24 differential	`CLK[0..23][p,n]` pins

Clock Resource	Device	Number of Resources Available	Source of Clock Resource
GCLK and RCLK networks	• Arria V GX A1 and A3 • Arria V GT C3	76	CLK[0..7][p,n] and CLK[12..23][p,n] pins, PLL clock outputs, and logic array
	• Arria V SX B3 and B5 • Arria V ST D3 and D5	82	CLK[0..11][p,n] and CLK[16..23][p,n] pins, PLL clock outputs, and logic array
	• Arria V GX A5, A7, B1, B3, B5, and B7 • Arria V GT C7, D3, and D7	88	CLK[0..23][p,n] pins, PLL clock outputs, and logic array
	Arria V GZ E1, E3, E5, and E7	92	
PCLK networks	• Arria V GX A1 and A3 • Arria V GT C3	120	DPA clock outputs, PLD-transceiver interface clocks, I/O pins, and logic array
	• Arria V GX A5 and A7 • Arria V GT C7	184	
	• Arria V SX B3 and B5 • Arria V ST D3 and D5	208	
	Arria V GZ E1 and E3	210	
	• Arria V GX B1 and B3 • Arria V GT D3	224	
	• Arria V GX B5 and B7 • Arria V GT D7	248	
	Arria V GZ E5 and E7	282

Types of Clock Networks

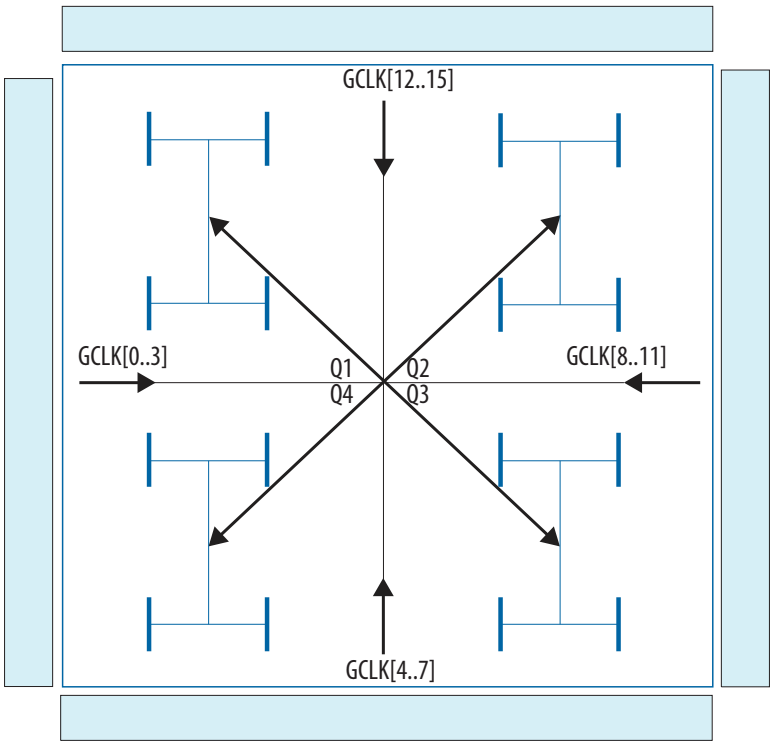
Global Clock Networks

Arria V devices provide GCLKs that can drive throughout the device. The GCLKs serve as low-skew clock sources for functional blocks, such as adaptive logic modules (ALMs), digital signal processing (DSP),

embedded memory, and PLLs. Arria V I/O elements (IOEs) and internal logic can also drive GCLKs to create internally-generated global clocks and other high fan-out control signals, such as synchronous or asynchronous clear and clock enable signals.

Figure 4-1: GCLK Networks in Arria V Devices

This figure represents the top view of the silicon die that corresponds to a reverse view of the device package.



Regional Clock Networks

RCLK networks are only applicable to the quadrant they drive into. RCLK networks provide the lowest clock insertion delay and skew for logic contained within a single device quadrant. The Arria V IOEs and internal logic within a given quadrant can also drive RCLKs to create internally generated regional clocks and other high fan-out control signals.

Figure 4-2: RCLK Networks in Arria V GX, GT, SX, and ST Devices

This figure represents the top view of the silicon die that corresponds to a reverse view of the device package.

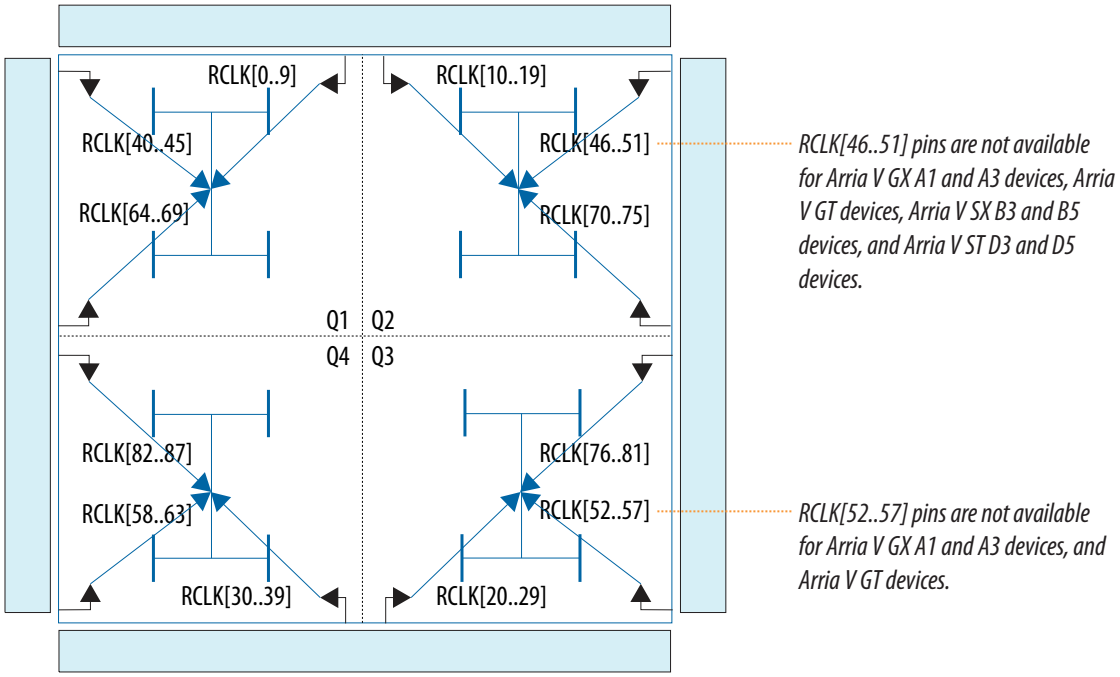


Figure 4-3: RCLK Networks in Arria V GZ Devices

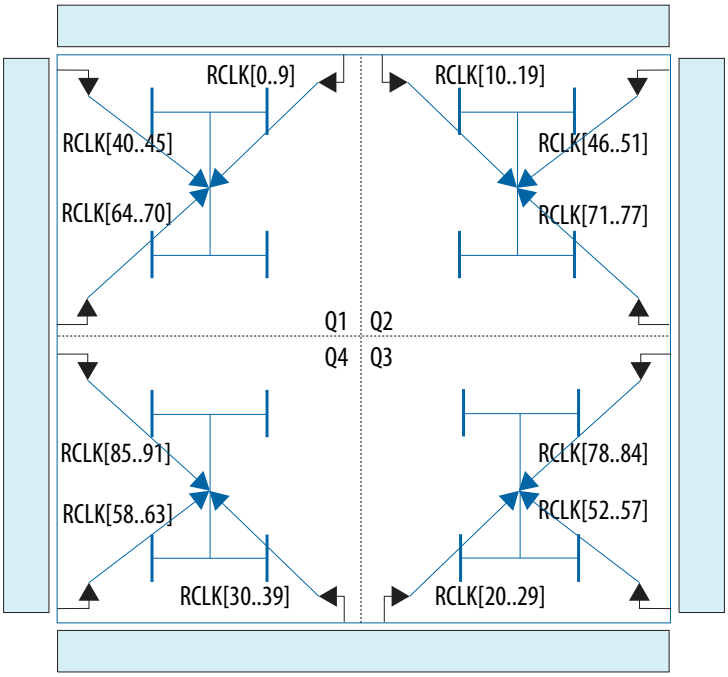
This figure represents the top view of the silicon die that corresponds to a reverse view of the device package.



Periphery Clock Networks

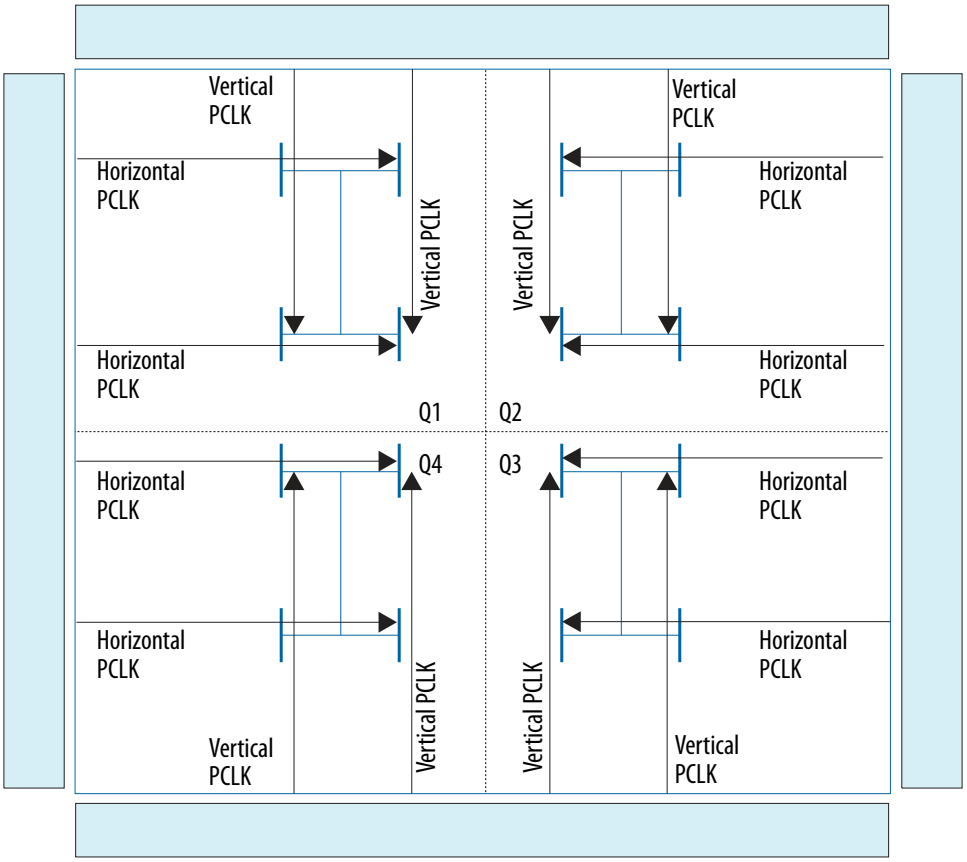
Depending on the routing direction, Arria V devices provide vertical PCLKs from the top and bottom periphery, and horizontal PCLKs from the left and right periphery.

Clock outputs from the dynamic phase aligner (DPA) block, programmable logic device (PLD)-transceiver interface clocks, I/O pins, and internal logic can drive the PCLK networks.

PCLKs have higher skew when compared with GCLK and RCLK networks. You can use PCLKs for general purpose routing to drive signals into and out of the Arria V device.

Figure 4-4: PCLK Networks in Arria V Devices

This figure represents the top view of the silicon die that corresponds to a reverse view of the device package.



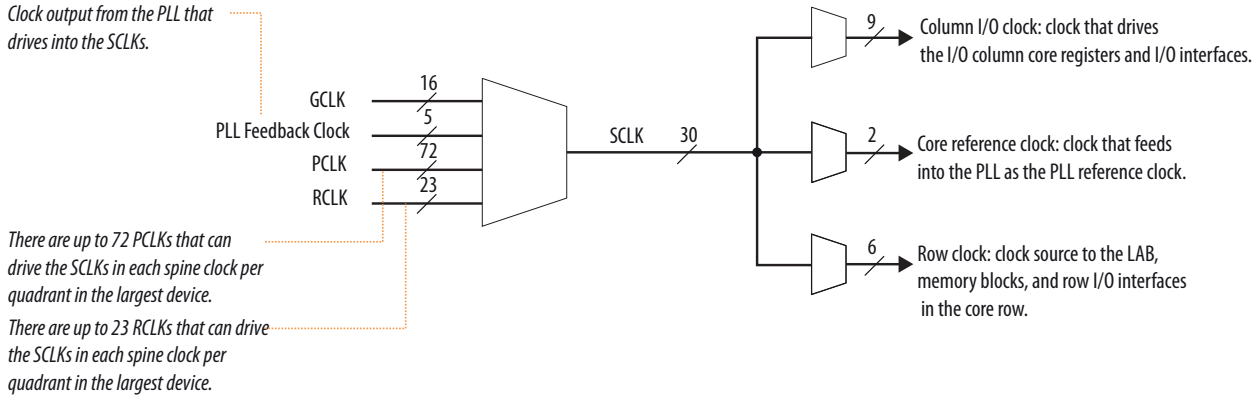
Clock Sources Per Quadrant

The Arria V devices provide 30 section clock (SCLK) networks in each spine clock per quadrant. The SCLK networks can drive six row clocks in each logic array block (LAB) row, nine column I/O clocks, and two core reference clocks. The SCLKs are the clock resources to the core functional blocks, PLLs, and I/O interfaces of the device.

A spine clock is another layer of routing between the GCLK, RCLK, and PCLK networks before each clock is connected to the clock routing for each LAB row. The settings for spine clocks are transparent. The Quartus II software automatically routes the spine clock based on the GCLK, RCLK, and PCLK networks.

The following figure shows SCLKs driven by the GCLK, RCLK, PCLK, or the PLL feedback clock networks in each spine clock per quadrant. The GCLK, RCLK, PCLK, and PLL feedback clocks share the same routing to the SCLKs. To ensure successful design fitting in the Quartus II software, the total number of clock resources must not exceed the SCLK limits in each region.

Figure 4-5: Hierarchical Clock Networks in Each Spine Clock Per Quadrant



Types of Clock Regions

This section describes the types of clock regions in Arria V devices.

Entire Device Clock Region

To form the entire device clock region, a source drives a signal in a GCLK network that can be routed through the entire device. The source is not necessarily a clock signal. This clock region has the maximum insertion delay when compared with other clock regions, but allows the signal to reach every destination in the device. It is a good option for routing global reset and clear signals or routing clocks throughout the device.

Regional Clock Region

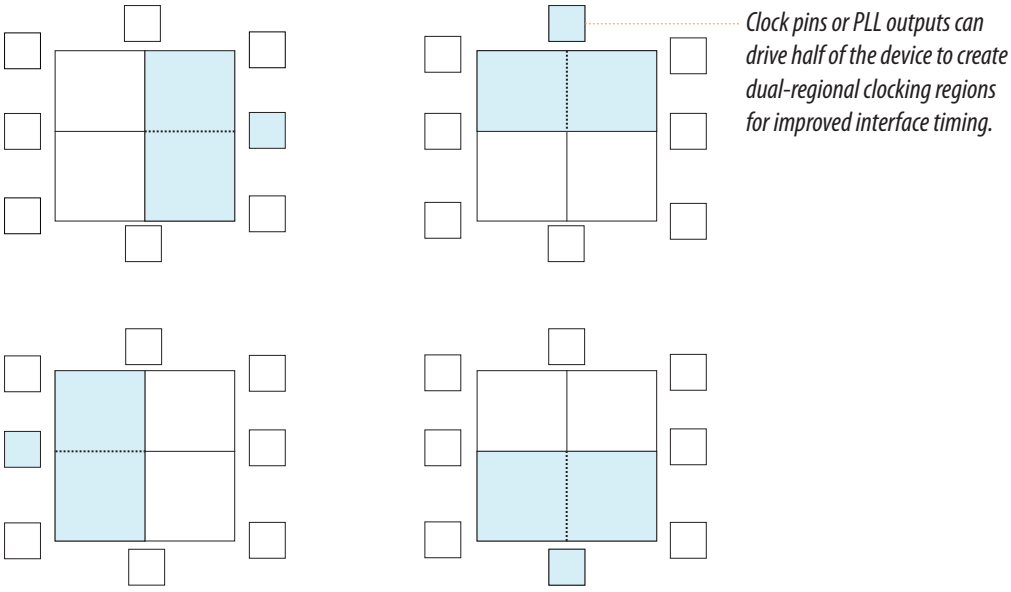
To form a regional clock region, a source drives a signal in a RCLK network that you can route throughout one quadrant of the device. This clock region provides the lowest skew in a quadrant. It is a good option if all the destinations are in a single quadrant.

Dual-Regional Clock Region

To form a dual-regional clock region, a single source (a clock pin or PLL output) generates a dual-regional clock by driving two RCLK networks (one from each quadrant). This technique allows destinations across two adjacent device quadrants to use the same low-skew clock. The routing of this signal on an entire side has approximately the same delay as a RCLK region. Internal logic can also drive a dual-regional clock network.

Figure 4-6: Dual-Regional Clock Region for Arria V Devices

This figure represents the top view of the silicon die that corresponds to a reverse view of the device package.



Clock Network Sources

In Arria V devices, clock input pins, PLL outputs, high-speed serial interface (HSSI) outputs, DPA outputs, and internal logic can drive the GCLK, RCLK, and PCLK networks.

Dedicated Clock Input Pins

You can use the dedicated clock input pins (`CLK[0..23][p,n]`) for high fan-out control signals, such as asynchronous clears, presets, and clock enables, for protocol signals through the GCLK or RCLK networks.

`CLK` pins can be either differential clocks or single-ended clocks. When you use the `CLK` pins as single-ended clock inputs, only the `CLK<#>p` pins have dedicated connections to the PLL. The `CLK<#>n` pins drive the PLLs over global or regional clock networks and do not have dedicated routing paths to the PLLs.

Driving a PLL over a global or regional clock can lead to higher jitter at the PLL input, and the PLL will not be able to fully compensate for the global or regional clock. Altera recommends using the `CLK<#>p` pins for optimal performance when you use single-ended clock inputs to drive the PLLs.

Internal Logic

You can drive each GCLK, RCLK, and horizontal PCLK network using LAB-routing and row clock to enable internal logic to drive a high fan-out, low-skew signal.

Note: Internally-generated GCLKs, RCLKs, or PCLKs cannot drive the Arria V PLLs. The input clock to the PLL has to come from dedicated clock input pins, PLL-fed GCLKs, or PLL-fed RCLKs.

DPA Outputs

Every DPA generates one PCLK to the core.

Related Information

High-Speed I/O Design Guidelines for Arria V Devices on page 6-7
Provides more information about DPA and HSSI outputs.

HSSI Outputs

Every three HSSI outputs generate a group of six PCLKs to the core.

Related Information

PLL Connectivity to GCLK and RCLK Networks for Arria V Devices

Clock Control Block

Every GCLK, RCLK, and PCLK network has its own clock control block. The control block provides the following features:

- Clock source selection (dynamic selection available only for GCLKs)
- Global clock multiplexing
- Clock power down (static or dynamic clock enable or disable available only for GCLKs and RCLKs)

Pin Mapping in Arria V Devices

Table 4-5: Mapping Between the Input Clock Pins, PLL Counter Outputs, and Clock Control Block Inputs

Clock	Fed by
inclk[0] and inclk[1]	Any of the four dedicated clock pins on the same side of the Arria V device.
inclk[2]	PLL counters C0 and C2 from the two center PLLs on the same side of the Arria V devices.
inclk[3]	PLL counters C1 and C3 from the two center PLLs on the same side of the Arria V devices.

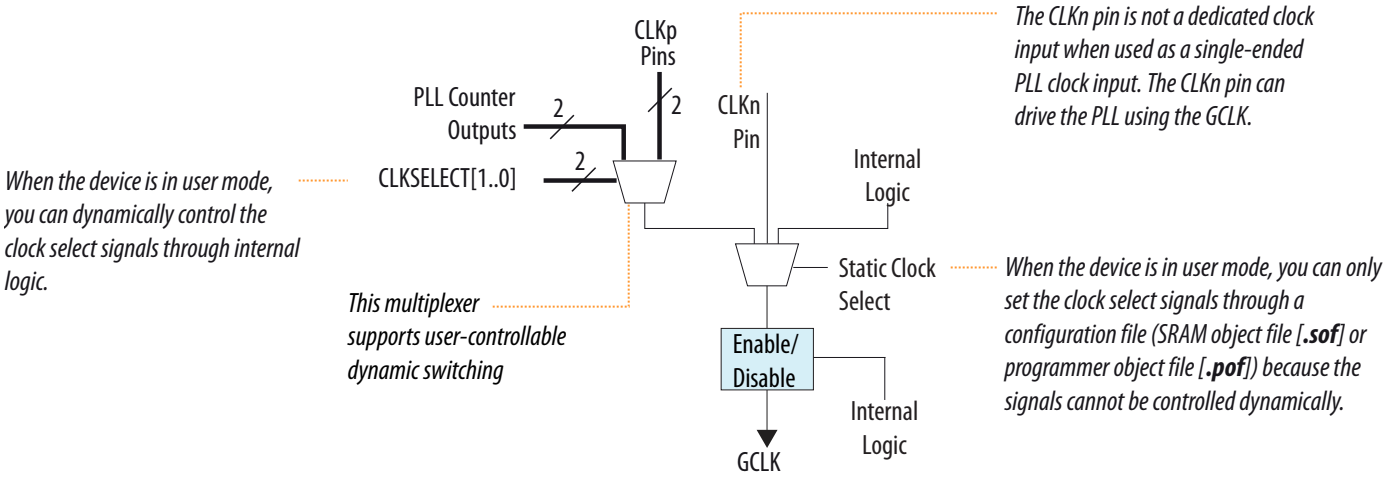
Note: You cannot use corner PLLs for dynamic clock control selection.

GCLK Control Block

You can select the clock source for the GCLK select block either statically or dynamically using internal logic to drive the multiplexer-select inputs.

When selecting the clock source dynamically, you can select either PLL outputs (such as `C0` or `C1`), or a combination of clock pins or PLL outputs.

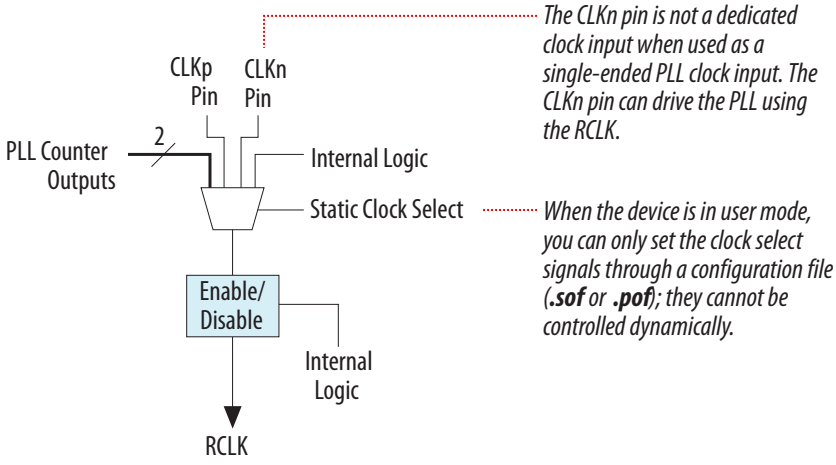
Figure 4-7: GCLK Control Block for Arria V Devices



RCLK Control Block

You can only control the clock source selection for the RCLK select block statically using configuration bit settings in the configuration file (**.sof** or **.pof**) generated by the Quartus II software.

Figure 4-8: RCLK Control Block for Arria V Devices



You can set the input clock sources and the `clkena` signals for the GCLK and RCLK network multiplexers through the Quartus II software using the ALTCLKCTRL megafunction.

Note: When selecting the clock source dynamically using the ALTCLKCTRL megafunction, choose the inputs using the `CLKSELECT[0..1]` signal. The inputs from the clock pins feed the `inclk[0..1]` ports of the multiplexer, and the PLL outputs feed the `inclk[2..3]` ports.

Clock Control Block (ALTCLKCTRL) Megafunction User Guide
Provides more information about ALTCLKCTRL megafunction.

Clock Power Down

You can power down the GCLK and RCLK clock networks using both static and dynamic approaches.

When a clock network is powered down, all the logic fed by the clock network is in off-state, reducing the overall power consumption of the device. The unused GCLK, RCLK, and PCLK networks are automatically powered down through configuration bit settings in the configuration file (**.sof** or **.pof**) generated by the Quartus II software.

The dynamic clock enable or disable feature allows the internal logic to control power-up or power-down synchronously on the GCLK and RCLK networks, including dual-regional clock regions. This feature is independent of the PLL and is applied directly on the clock network.

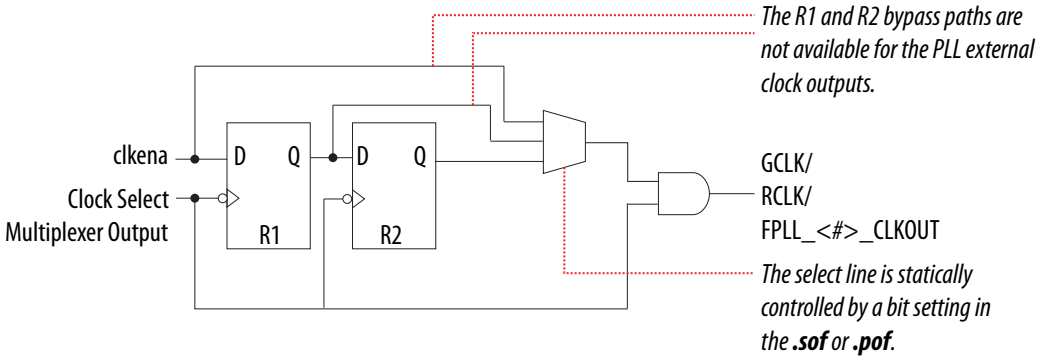
Note: You cannot dynamically enable or disable GCLK or RCLK networks that drive PLLs.

Clock Enable Signals

You cannot use the clock enable and disable circuit of the clock control block if the GCLK or RCLK output drives the input of a PLL.

Figure 4-11: clkena Implementation with Clock Enable and Disable Circuit

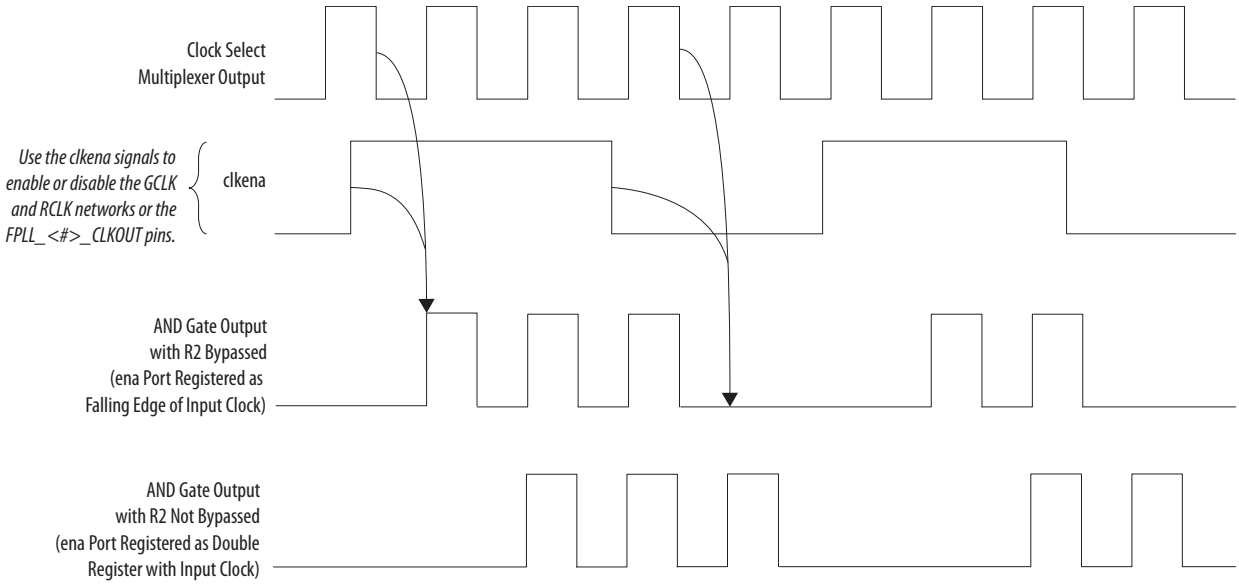
This figure shows the implementation of the clock enable and disable circuit of the clock control block.



The clkena signals are supported at the clock network level instead of at the PLL output counter level. This allows you to gate off the clock even when you are not using a PLL. You can also use the clkena signals to control the dedicated external clocks from the PLLs.

Figure 4-12: Example of clkena Signals

This figure shows a waveform example for a clock output enable. The clkena signal is synchronous to the falling edge of the clock output.



Arria V devices have an additional metastability register that aids in asynchronous enable and disable of the GCLK and RCLK networks. You can optionally bypass this register in the Quartus II software.

The PLL can remain locked, independent of the clkena signals, because the loop-related counters are not affected. This feature is useful for applications that require a low-power or sleep mode. The clkena signal can also disable clock outputs if the system is not tolerant of frequency overshoot during resynchronization.

Arria V PLLs

PLLs provide robust clock management and synthesis for device clock management, external system clock management, and high-speed I/O interfaces.

The Arria V device family contains fractional PLLs that can function as fractional PLLs or integer PLLs. The output counters in Arria V devices are dedicated to each fractional PLL that support integer or fractional frequency synthesis.

Two adjacent PLLs share 18 `C` output counters. Any number of `C` counters can be assigned to each PLL, as long as the total number used by the two PLLs is 18 or less.

The Arria V devices offer up to 16 fractional PLLs in the larger densities. All Arria V fractional PLLs have the same core analog structure and features support.

Table 4-6: PLL Features in Arria V Devices

Feature	Support
Integer PLL	Yes
Fractional PLL	Yes
`C` output counters	18
`M`, `N`, `C` counter sizes	1 to 512
Dedicated external clock outputs	4 single-ended or 2 single-ended and 1 differential
Dedicated clock input pins	4 single-ended or 4 differential
External feedback input pin	Single-ended or differential
Spread-spectrum input clock tracking	Yes (7)
Source synchronous compensation	Yes
Direct compensation	Yes
Normal compensation	Yes
Zero-delay buffer compensation	Yes
External feedback compensation	Yes
LVDS compensation	Yes
Voltage-controlled oscillator (VCO) output drives the DPA clock	Yes
Phase shift resolution	78.125 ps (8)
Programmable duty cycle	Yes
Power down mode	Yes

(7) Provided input clock jitter is within input jitter tolerance specifications. The modulation frequency of the input clock is below the PLL bandwidth which is specified in the Fitter report.

(8) The smallest phase shift is determined by the VCO period divided by eight. For degree increments, the Arria V device can shift all output frequencies in increments of at least 45°. Smaller degree increments are possible depending on the frequency and divide parameters.

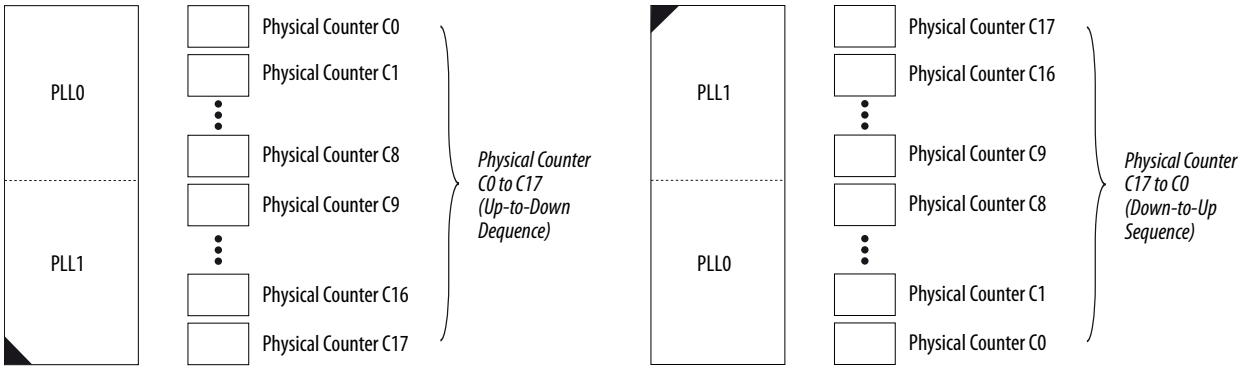
PLL Physical Counters in Arria V Devices

The physical counters for the fractional PLLs are arranged in the following sequences:

- Up-to-down
- Down-to-up

Figure 4-13: PLL Physical Counters Orientation for Arria V Devices

This figure represents the top view of the silicon die that corresponds to a reverse view of the device package.



PLL Locations in Arria V Devices

Arria V devices provide PLLs for the transceiver channels. These PLLs are located in a strip, where the strip refers to an area in the FPGA.

The total number of PLLs in the Arria V devices includes the PLLs in the PLL strip. However, the transceivers can only use the PLLs located in the strip.

The following figures show the physical locations of the fractional PLLs. Every index represents one fractional PLL in the device. The physical locations of the fractional PLLs correspond to the coordinates in the Quartus II Chip Planner.

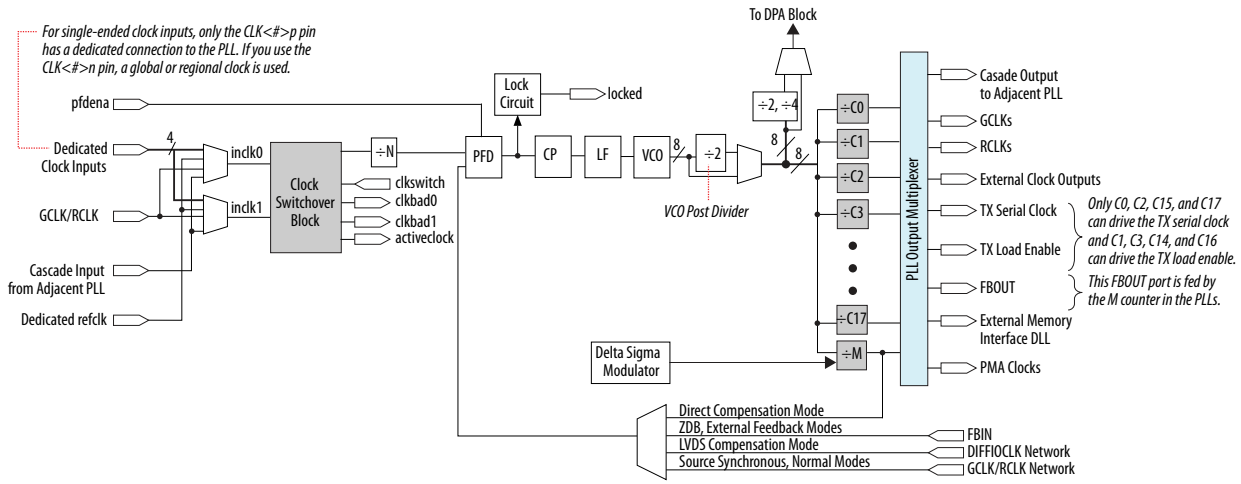
Fractional PLL Architecture

Figure 4-21: Fractional PLL High-Level Block Diagram for Arria V Devices



Fractional PLL Usage

You can configure the fractional PLL to function either in the integer or in the enhanced fractional mode. One fractional PLL can use up to 18 output counters and all external clock outputs. Two adjacent fractional PLLs share the 18 output counters.

Fractional PLLs can be used as follows:

- Reduce the number of required oscillators on the board
- Reduce the clock pins used in the FPGA by synthesizing multiple clock frequencies from a single reference clock source
- Compensate clock network delay
- Zero delay buffering
- Transmit clocking for transceivers

PLL Cascading

Arria V devices support two types of PLL cascading.

PLL-to-PLL Cascading

This cascading mode synthesizes a more precise output frequency than a single PLL in integer mode. Cascading two PLLs in integer mode expands the effective range of the pre-scale counter, `N` and the multiply counter, `M`.

Arria V devices use two types of input clock sources.

- The `adjpllin` input clock source is used for inter-cascading between fracturable fractional PLLs.
- The `cclk` input clock source is used for intra-cascading within fracturable fractional PLLs.

Altera recommends using a low bandwidth setting for the source (upstream) PLL and a high bandwidth setting for destination (downstream) PLL.

Counter-Output-to-Counter-Output Cascading

This cascading mode synthesizes a lower frequency output than a single post-scale counter, `C`. Cascading two `C` counters expands the effective range of `C` counters.

PLL External Clock I/O Pins

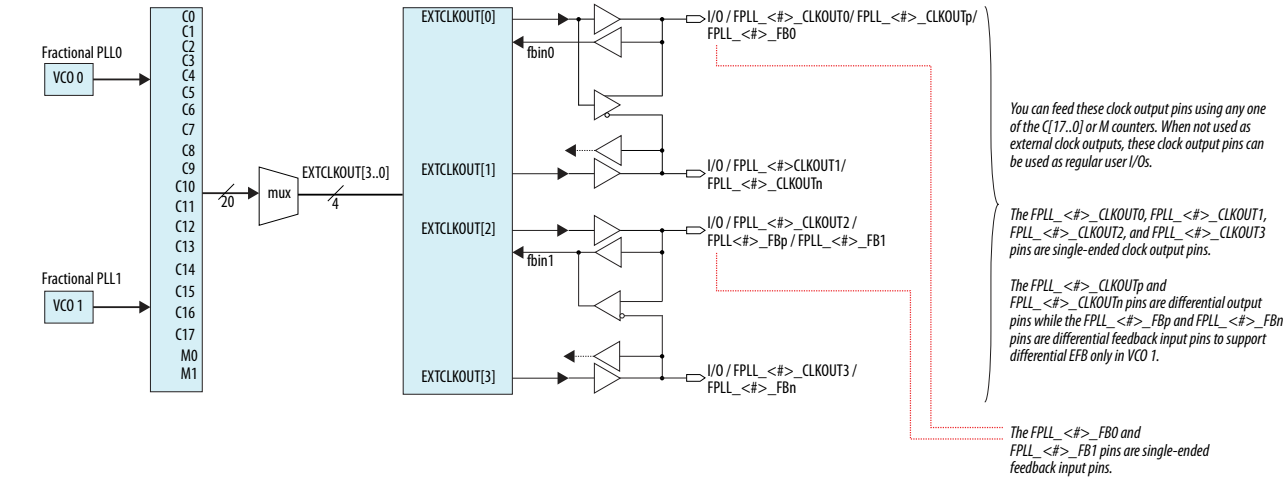
Two adjacent fractional PLLs share four dual-purpose clock I/O pins, organized as one of the following combinations:

- Four single-ended clock outputs
- Two single-ended outputs and one differential clock output
- Four single-ended clock outputs and two single-ended feedback inputs in the I/O driver feedback for zero delay buffer (ZDB) mode support
- Two single-ended clock outputs and two single-ended feedback inputs for single-ended external feedback (EFB) mode support
- One differential clock output and one differential feedback input for differential EFB support (only one of the two adjacent fractional PLLs can support differential EFB at one time while the other fractional PLL can be used for general-purpose clocking)

Note: The middle fractional PLLs on the left and right sides of Arria V GX B5 and B7 devices, and Arria V GT D7 device do not support external clock outputs.

The following figure shows that any of the output counters (`C[0..17]`) or the `M` counter on the PLLs can feed the dedicated external clock outputs. Therefore, one counter or frequency can drive all output pins available from a given PLL.

Figure 4-22: Dual-Purpose Clock I/O Pins Associated with PLL for Arria V Devices



Each pin of a single-ended output pair can be either in-phase or 180° out-of-phase. To implement the 180° out-of-phase pin in a pin pair, the Quartus II software places a NOT gate in the design into the IOE.

The clock output pin pairs support the following I/O standards:

- Same I/O standard for the pin pairs
- LVDS
- Differential high-speed transceiver logic (HSTL)
- Differential SSTL

Arria V PLLs can drive out to any regular I/O pin through the GCLK or RCLK network. You can also use the external clock output pins as user I/O pins if you do not require external PLL clocking.

PLL Control Signals

You can use the `areset` signal to control PLL operation and resynchronization, and use the `locked` signal to observe the status of the PLL.

areset

The `areset` signal is the reset or resynchronization input for each PLL. The device input pins or internal logic can drive these input signals.

When `areset` is driven high, the PLL counters reset, clearing the PLL output and placing the PLL out-of-lock. The VCO is then set back to its nominal setting. When `areset` is driven low again, the PLL resynchronizes to its input as it re-locks.

You must assert the `areset` signal every time the PLL loses lock to guarantee the correct phase relationship between the PLL input and output clocks. You can set up the PLL to automatically reset (self-reset) after a loss-of-lock condition using the Quartus II MegaWizard Plug-In Manager.

You must include the `areset` signal if either of the following conditions is true:

- PLL reconfiguration or clock switchover is enabled in the design
- Phase relationships between the PLL input and output clocks must be maintained after a loss-of-lock condition

Note: If the input clock to the PLL is not toggling or is unstable after power up, assert the `areset` signal after the input clock is stable and within specifications.

locked

The `locked` signal output of the PLL indicates the following conditions:

- The PLL has locked onto the reference clock.
- The PLL clock outputs are operating at the desired phase and frequency set in the MegaWizard Plug-In Manager.

The lock detection circuit provides a signal to the core logic. The signal indicates when the feedback clock has locked onto the reference clock both in phase and frequency.

Clock Feedback Modes

This section describes the following clock feedback modes:

- Source synchronous
- LVDS compensation
- Direct
- Normal compensation
- ZDB
- EFB

Each mode allows clock multiplication and division, phase shifting, and programmable duty cycle.

The input and output delays are fully compensated by a PLL only when using the dedicated clock input pins associated with a given PLL as the clock source.

The input and output delays may not be fully compensated in the Quartus II software for the following conditions:

- When a GCLK or RCLK network drives the PLL
- When the PLL is driven by a dedicated clock pin that is not associated with the PLL

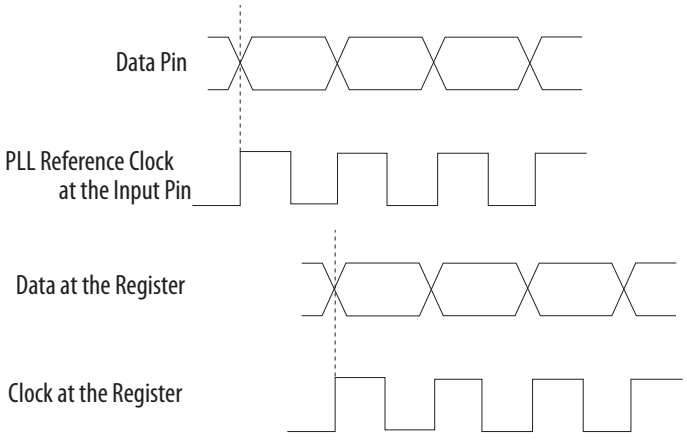
For example, when you configure a PLL in ZDB mode, the PLL input is driven by an associated dedicated clock input pin. In this configuration, a fully compensated clock path results in zero delay between the clock input and one of the clock outputs from the PLL. However, if the PLL input is fed by a non-dedicated input (using the GCLK network), the output clock may not be perfectly aligned with the input clock.

Source Synchronous Mode

If the data and clock arrive at the same time on the input pins, the same phase relationship is maintained at the clock and data ports of any IOE input register. Data and clock signals at the IOE experience similar buffer delays as long as you use the same I/O standard.

Altera recommends source synchronous mode for source synchronous data transfers.

Figure 4-23: Example of Phase Relationship Between Clock and Data in Source Synchronous Mode



The source synchronous mode compensates for the delay of the clock network used and any difference in the delay between the following two paths:

- Data pin to the IOE register input
- Clock input pin to the PLL phase frequency detector (PFD) input

The Arria V PLL can compensate multiple pad-to-input-register paths, such as a data bus when it is set to use source synchronous compensation mode.

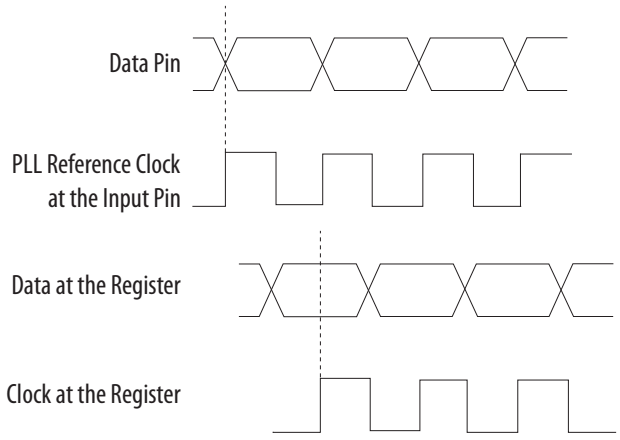
LVDS Compensation Mode

The purpose of LVDS compensation mode is to maintain the same data and clock timing relationship seen at the pins of the internal serializer/deserializer (SERDES) capture register, except that the clock is inverted (180° phase shift). Thus, LVDS compensation mode ideally compensates for the delay of the LVDS clock network, including the difference in delay between the following two paths:

- Data pin-to-SERDES capture register
- Clock input pin-to-SERDES capture register

The output counter must provide the 180° phase shift.

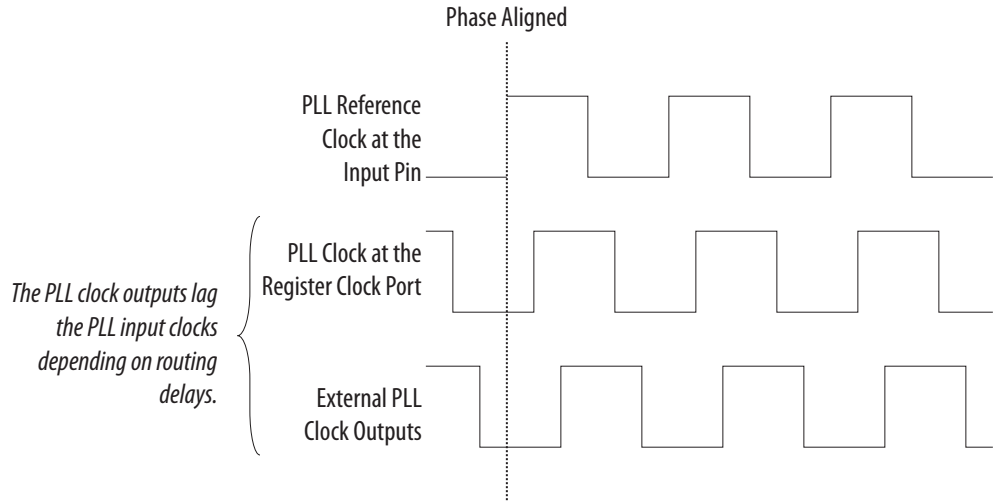
Figure 4-24: Example of Phase Relationship Between the Clock and Data in LVDS Compensation Mode



Direct Mode

In direct mode, the PLL does not compensate for any clock networks. This mode provides better jitter performance because the clock feedback into the PFD passes through less circuitry. Both the PLL internal- and external-clock outputs are phase-shifted with respect to the PLL clock input.

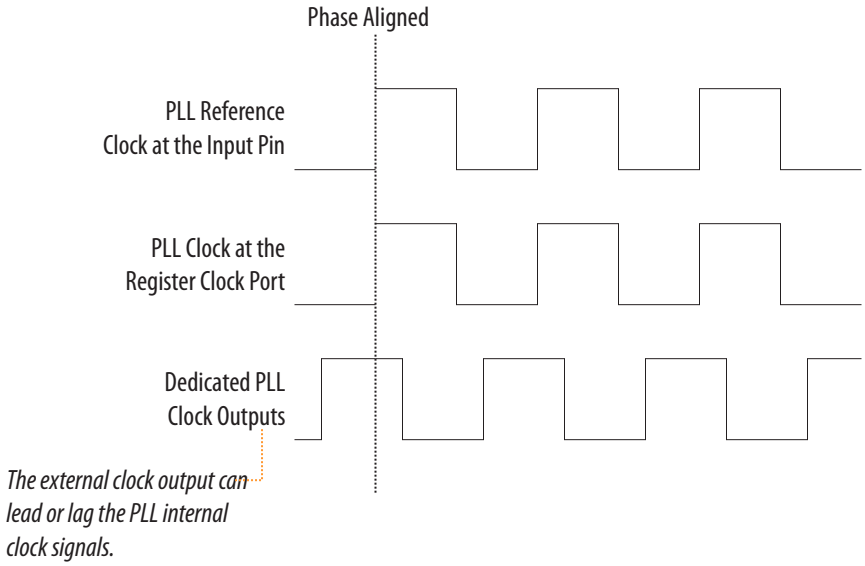
Figure 4-25: Example of Phase Relationship Between the PLL Clocks in Direct Mode



Normal Compensation Mode

An internal clock in normal compensation mode is phase-aligned to the input clock pin. The external clock output pin has a phase delay relative to the clock input pin if connected in this mode. The Quartus II TimeQuest Timing Analyzer reports any phase difference between the two. In normal compensation mode, the delay introduced by the GCLK or RCLK network is fully compensated.

Figure 4-26: Example of Phase Relationship Between the PLL Clocks in Normal Compensation Mode



Zero-Delay Buffer Mode

In ZDB mode, the external clock output pin is phase-aligned with the clock input pin for zero delay through the device. This mode is supported on all Arria V PLLs.

When using this mode, you must use the same I/O standard on the input clocks and clock outputs to guarantee clock alignment at the input and output pins. You cannot use differential I/O standards on the PLL clock input or output pins.

To ensure phase alignment between the `clk` pin and the external clock output (`CLKOUT`) pin in ZDB mode, instantiate a bidirectional I/O pin in the design. The bidirectional I/O pin serves as the feedback path connecting the `fbout` and `fbin` ports of the PLL. The bidirectional I/O pin must always be assigned a single-ended I/O standard. The PLL uses this bidirectional I/O pin to mimic and compensate for the output delay from the clock output port of the PLL to the external clock output pin.

Note: To avoid signal reflection when using ZDB mode, do not place board traces on the bidirectional I/O pin.

Figure 4-27: ZDB Mode in Arria V PLLs

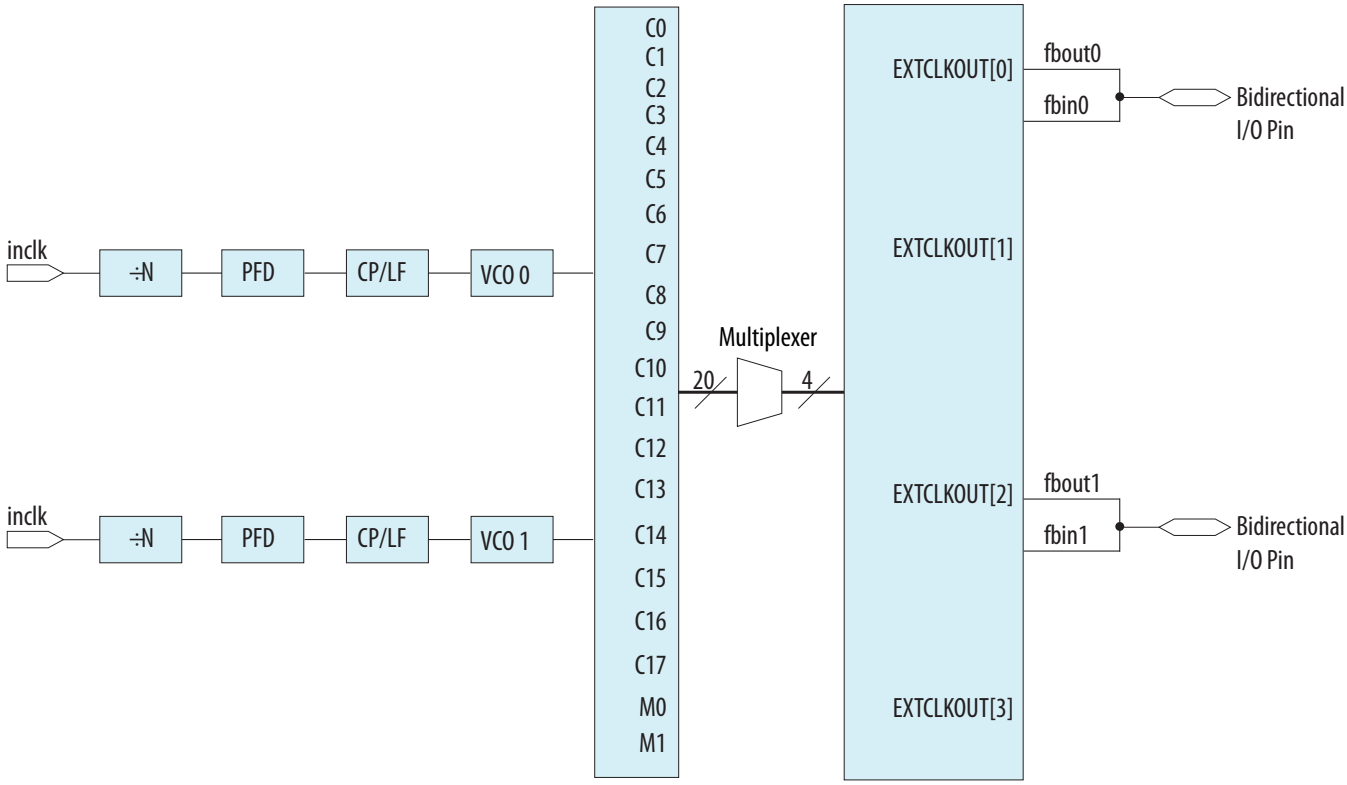


Figure 4-28: Example of Phase Relationship Between the PLL Clocks in ZDB Mode

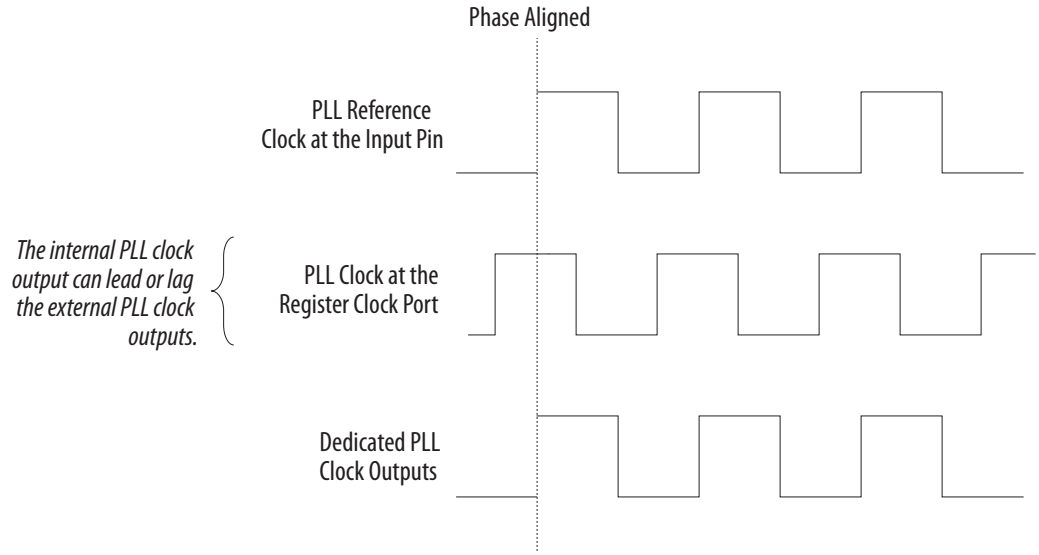

Related Information

PLL External Clock I/O Pins on page 4-24
Provides more information about PLL clock outputs.

External Feedback Mode

In EFB mode, the output of the `M` counter (`fbout`) feeds back to the PLL `fbin` input (using a trace on the board) and becomes part of the feedback loop.

One of the dual-purpose external clock outputs becomes the `fbin` input pin in this mode. The external feedback input pin, `fbin` is phase-aligned with the clock input pin. Aligning these clocks allows you to remove clock delay and skew between devices.

When using EFB mode, you must use the same I/O standard on the input clock, feedback input, and clock outputs.

Figure 4-29: EFB Mode in Arria V Devices

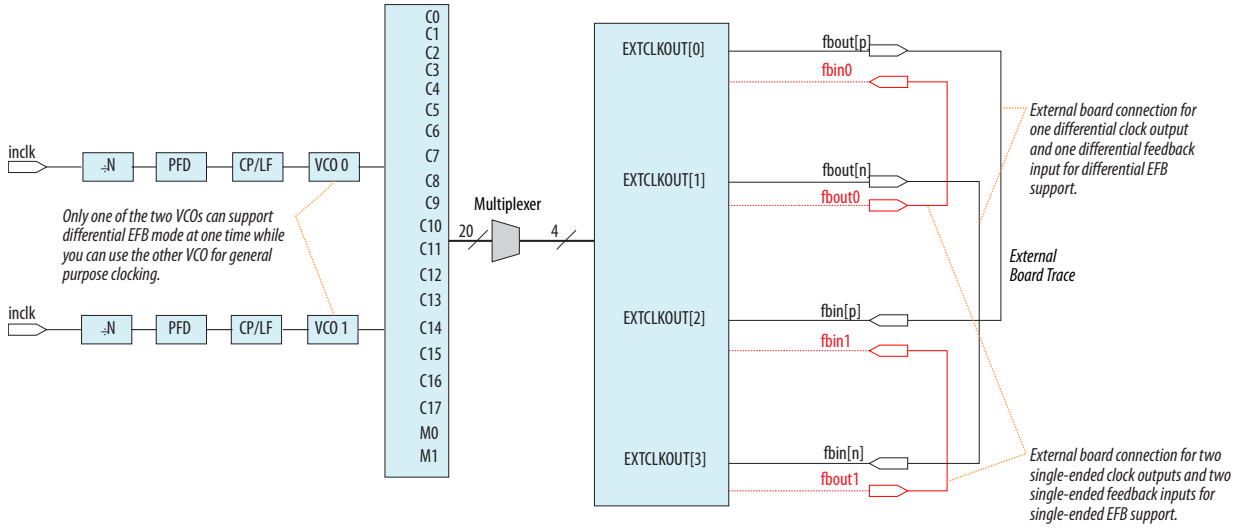

Figure 4-30: Example of Phase Relationship Between the PLL Clocks in EFB Mode

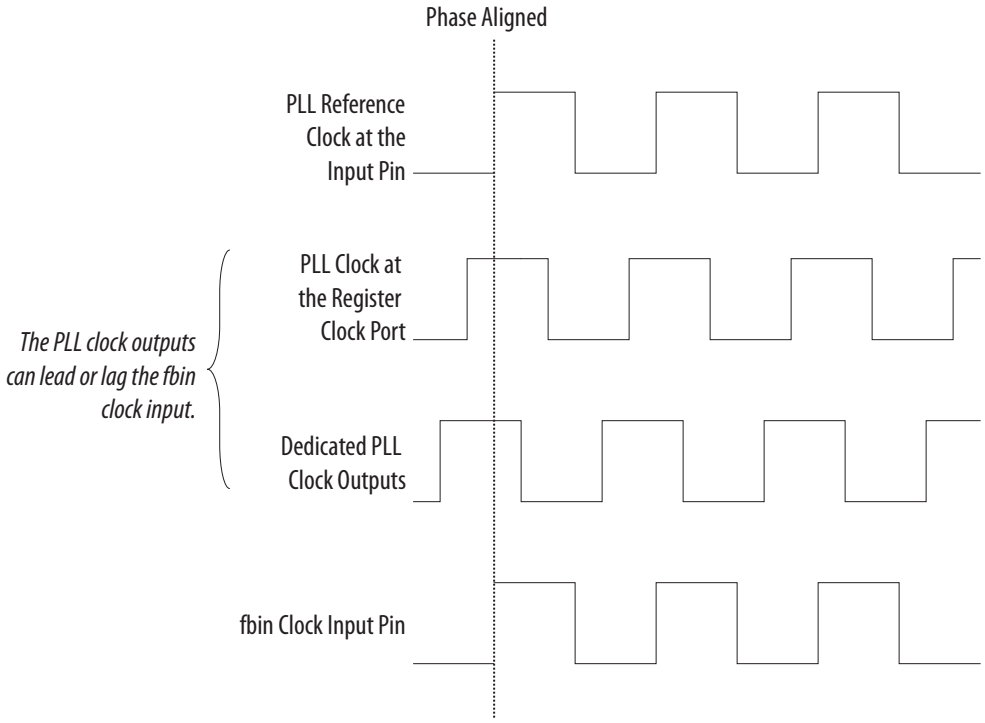


Related Information

PLL External Clock I/O Pins on page 4-24
Provides more information about PLL clock outputs.

Clock Multiplication and Division

Each Arria V PLL provides clock synthesis for PLL output ports using the M/(N × C) scaling factors. The input clock is divided by a pre-scale factor, N, and is then multiplied by the M feedback factor. The control loop drives the VCO to match $f_{in} \times (M/N)$.

The Quartus II software automatically chooses the appropriate scaling factors according to the input frequency, multiplication, and division values entered into the ALTERA_PLL megafunction.

VCO Post Divider

A VCO post divider is inserted after the VCO. When you enable the VCO post divider, the VCO post divider divides the VCO frequency by two. When the VCO post divider is bypassed, the VCO frequency goes to the output port without being divided by two.

Post-Scale Counter, C

Each output port has a unique post-scale counter, C, that divides down the output from the VCO post divider. For multiple PLL outputs with different frequencies, the VCO is set to the least common multiple of the output frequencies that meets its frequency specifications. For example, if the output frequencies required from one PLL are 33 and 66 MHz, the Quartus II software sets the VCO to 660 MHz (the least common multiple of 33 and 66 MHz within the VCO range). Then the post-scale counters, C, scale down the VCO frequency for each output port.

Pre-Scale Counter, N and Multiply Counter, M

Each PLL has one pre-scale counter, N, and one multiply counter, M, with a range of 1 to 512 for both M and N. The N counter does not use duty-cycle control because the only purpose of this counter is to calculate frequency division. The post-scale counters have a 50% duty cycle setting. The high- and low-count values for each counter range from 1 to 256. The sum of the high- and low-count values chosen for a design selects the divide value for a given counter.

Delta-Sigma Modulator

The delta-sigma modulator (DSM) is used together with the M multiply counter to enable the PLL to operate in fractional mode. The DSM dynamically changes the M counter divide value on a cycle to cycle basis. The different M counter values allow the "average" M counter value to be a non-integer.

Fractional Mode

In fractional mode, the M counter divide value equals to the sum of the "clock high" count, "clock low" count, and the fractional value. The fractional value is equal to K/2^*X*, where K is an integer between 0 and (2^*X* – 1), and *X* = 8, 16, 24, or 32.

Integer Mode

For PLL operating in integer mode, M is an integer value and DSM is disabled.

Related Information

Altera Phase-Locked Loop (ALTERA_PLL) Megafunction User Guide
Provides more information about PLL software support in the Quartus II software.

Programmable Phase Shift

The programmable phase shift feature allows the PLLs to generate output clocks with a fixed phase offset.

The VCO frequency of the PLL determines the precision of the phase shift. The minimum phase shift increment is 1/8 of the VCO period. For example, if a PLL operates with a VCO frequency of 1000 MHz, phase shift steps of 125 ps are possible.

The Quartus II software automatically adjusts the VCO frequency according to the user-specified phase shift values entered into the megafunction.

Programmable Duty Cycle

The programmable duty cycle allows PLLs to generate clock outputs with a variable duty cycle. This feature is supported on the PLL post-scale counters.

The duty-cycle setting is achieved by a low and high time-count setting for the post-scale counters. To determine the duty cycle choices, the Quartus II software uses the frequency input and the required multiply or divide rate.

The post-scale counter value determines the precision of the duty cycle. The precision is defined as 50% divided by the post-scale counter value. For example, if the `C0` counter is 10, steps of 5% are possible for duty-cycle choices from 5% to 90%. If the PLL is in external feedback mode, set the duty cycle for the counter driving the `fbin` pin to 50%.

Combining the programmable duty cycle with programmable phase shift allows the generation of precise non-overlapping clocks.

Clock Switchover

The clock switchover feature allows the PLL to switch between two reference input clocks. Use this feature for clock redundancy or for a dual-clock domain application where a system turns on the redundant clock if the previous clock stops running. The design can perform clock switchover automatically when the clock is no longer toggling or based on a user control signal, `clkswitch`.

The following clock switchover modes are supported in Arria V PLLs:

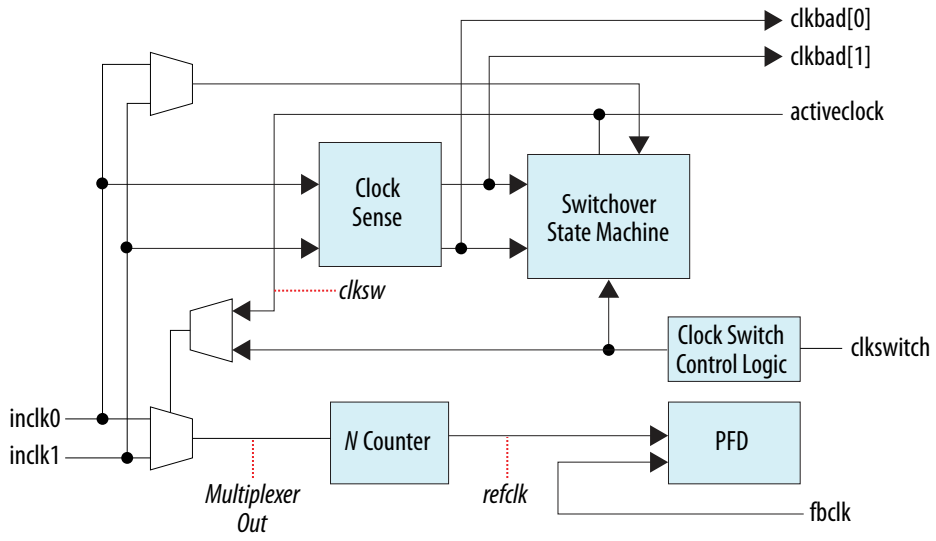
- Automatic switchover—The clock sense circuit monitors the current reference clock. If the current reference clock stops toggling, the reference clock automatically switches to `inclk0` or `inclk1` clock.
- Manual clock switchover—Clock switchover is controlled using the `clkswitch` signal. When the `clkswitch` signal goes from logic low to logic high, and stays high for at least three clock cycles, the reference clock to the PLL is switched from `inclk0` to `inclk1`, or vice-versa.
- Automatic switchover with manual override—This mode combines automatic switchover and manual clock switchover. When the `clkswitch` signal goes high, it overrides the automatic clock switchover function. As long as the `clkswitch` signal is high, further switchover action is blocked.

Automatic Switchover

Arria V PLLs support a fully configurable clock switchover capability.

Figure 4-31: Automatic Clock Switchover Circuit Block Diagram

This figure shows a block diagram of the automatic switchover circuit built into the PLL.



When the current reference clock is not present, the clock sense block automatically switches to the backup clock for PLL reference. You can select a clock source as the backup clock by connecting it to the `inclk1` port of the PLL in your design.

The clock switchover circuit sends out three status signals—`clkbad[0]`, `clkbad[1]`, and `activeclock`—from the PLL to implement a custom switchover circuit in the logic array.

In automatic switchover mode, the `clkbad[0]` and `clkbad[1]` signals indicate the status of the two clock inputs. When they are asserted, the clock sense block detects that the corresponding clock input has stopped toggling. These two signals are not valid if the frequency difference between `inclk0` and `inclk1` is greater than 20%.

The `activeclock` signal indicates which of the two clock inputs (`inclk0` or `inclk1`) is being selected as the reference clock to the PLL. When the frequency difference between the two clock inputs is more than 20%, the `activeclock` signal is the only valid status signal.

Note: Glitches in the input clock may cause the frequency difference between the input clocks to be more than 20%.

Use the switchover circuitry to automatically switch between `inclk0` and `inclk1` when the current reference clock to the PLL stops toggling. You can switch back and forth between `inclk0` and `inclk1` any number of times when one of the two clocks fails and the other clock is available.

For example, in applications that require a redundant clock with the same frequency as the reference clock, the switchover state machine generates a signal (`clksw`) that controls the multiplexer select input. In this case, `inclk1` becomes the reference clock for the PLL.

When using automatic clock switchover mode, the following requirements must be satisfied:

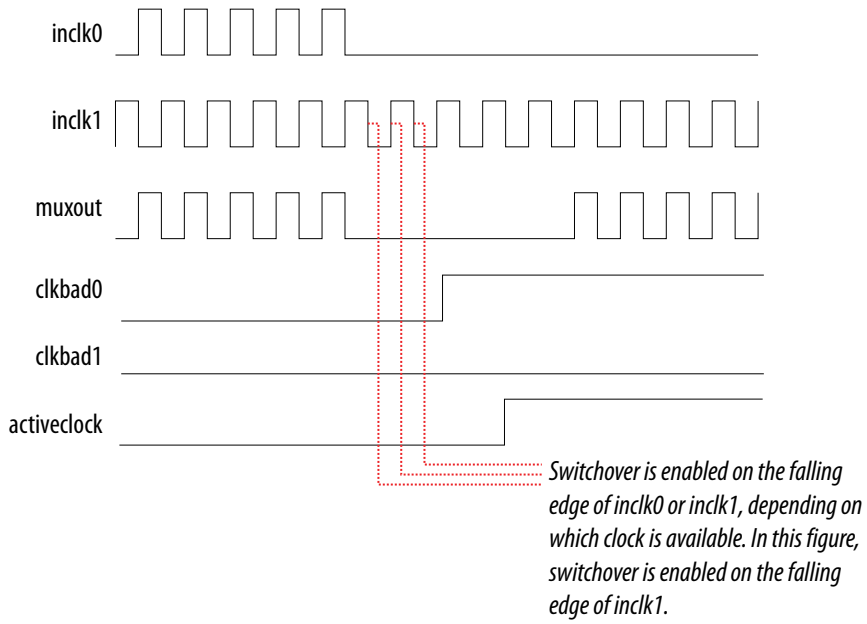
- Both clock inputs must be running when the FPGA is configured.
- The period of the two clock inputs can differ by no more than 20%.

If the current clock input stops toggling while the other clock is also not toggling, switchover is not initiated and the clkbad[0..1] signals are not valid. If both clock inputs are not the same frequency, but their period difference is within 20%, the clock sense block detects when a clock stops toggling. However, the PLL may lose lock after the switchover is completed and needs time to relock.

Note: Altera recommends resetting the PLL using the areset signal to maintain the phase relationships between the PLL input and output clocks when using clock switchover.

Figure 4-32: Automatic Switchover After Loss of Clock Detection

This figure shows an example waveform of the switchover feature in automatic switchover mode. In this example, the inclk0 signal is stuck low. After the inclk0 signal is stuck at low for approximately two clock cycles, the clock sense circuitry drives the clkbad[0] signal high. Since the reference clock signal is not toggling, the switchover state machine controls the multiplexer through the clkswitch signal to switch to the backup clock, inclk1.



Automatic Switchover with Manual Override

In automatic switchover with manual override mode, you can use the clkswitch signal for user- or system-controlled switch conditions. You can use this mode for same-frequency switchover, or to switch between inputs of different frequencies.

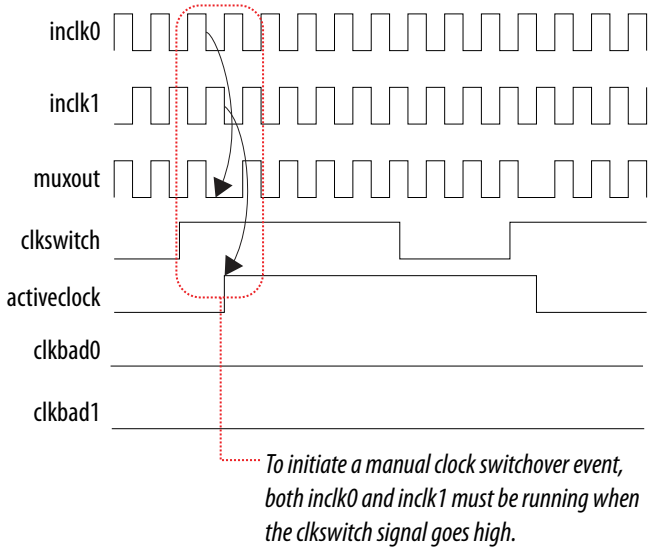
For example, if inclk0 is 66 MHz and inclk1 is 200 MHz, you must control switchover using the clkswitch signal. The automatic clock-sense circuitry cannot monitor clock input (inclk0 and inclk1) frequencies with a frequency difference of more than 100% (2×).

This feature is useful when the clock sources originate from multiple cards on the backplane, requiring a system-controlled switchover between the frequencies of operation.

You must choose the backup clock frequency and set the M, N, C, and K counters so that the VCO operates within the recommended operating frequency range. The ALTERA_PLL MegaWizard Plug-in Manager notifies you if a given combination of inclk0 and inclk1 frequencies cannot meet this requirement.

Figure 4-33: Clock Switchover Using the `clkswitch` (Manual) Control

This figure shows a clock switchover waveform controlled by the `clkswitch` signal. In this case, both clock sources are functional and `inclk0` is selected as the reference clock; the `clkswitch` signal goes high, which starts the switchover sequence. On the falling edge of `inclk0`, the counter's reference clock, `muxout`, is gated off to prevent clock glitching. On the falling edge of `inclk1`, the reference clock multiplexer switches from `inclk0` to `inclk1` as the PLL reference. The `activeclock` signal changes to indicate the clock which is currently feeding the PLL.



In automatic override with manual switchover mode, the `activeclock` signal mirrors the `clkswitch` signal. Since both clocks are still functional during the manual switch, neither `clkbad` signal goes high. Because the switchover circuit is positive-edge sensitive, the falling edge of the `clkswitch` signal does not cause the circuit to switch back from `inclk1` to `inclk0`. When the `clkswitch` signal goes high again, the process repeats.

The `clkswitch` signal and automatic switch work only if the clock being switched to is available. If the clock is not available, the state machine waits until the clock is available.

Manual Clock Switchover

In manual clock switchover mode, the `clkswitch` signal controls whether `inclk0` or `inclk1` is selected as the input clock to the PLL. By default, `inclk0` is selected.

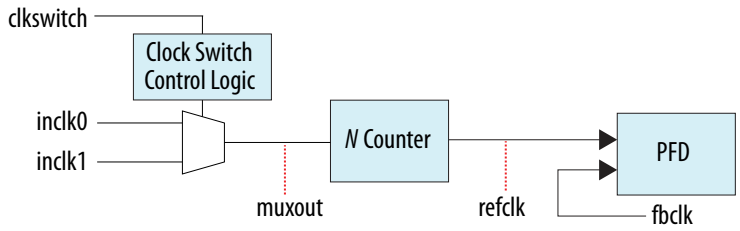
A clock switchover event is initiated when the `clkswitch` signal transitions from logic low to logic high, and being held high for at least three `inclk` cycles.

You must bring the `clkswitch` signal back low again to perform another switchover event. If you do not require another switchover event, you can leave the `clkswitch` signal in a logic high state after the initial switch.

Pulsing the `clkswitch` signal high for at least three `inclk` cycles performs another switchover event.

If `inclk0` and `inclk1` are different frequencies and are always running, the `clkswitch`signal minimum high time must be greater than or equal to three of the slower frequency `inclk0` and `inclk1` cycles.

Figure 4-34: Manual Clock Switchover Circuitry in Arria V PLLs



You can delay the clock switchover action by specifying the switchover delay in the ALTERA_PLL megafunction. When you specify the switchover delay, the `clkswitch` signal must be held high for at least three `inclk` cycles plus the number of the delay cycles that has been specified to initiate a clock switchover.

Guidelines

When implementing clock switchover in Arria V PLLs, use the following guidelines:

- Automatic clock switchover requires that the `inclk0` and `inclk1` frequencies be within 20% of each other. Failing to meet this requirement causes the `clkbad[0]` and `clkbad[1]` signals to not function properly.
- When using manual clock switchover, the difference between `inclk0` and `inclk1` can be more than 100% (2×). However, differences in frequency, phase, or both, of the two clock sources will likely cause the PLL to lose lock. Resetting the PLL ensures that you maintain the correct phase relationships between the input and output clocks.
- Both `inclk0` and `inclk1` must be running when the `clkswitch` signal goes high to initiate the manual clock switchover event. Failing to meet this requirement causes the clock switchover to not function properly.
- Applications that require a clock switchover feature and a small frequency drift must use a low-bandwidth PLL. When referencing input clock changes, the low-bandwidth PLL reacts more slowly than a high-bandwidth PLL. When switchover happens, a low-bandwidth PLL propagates the stopping of the clock to the output more slowly than a high-bandwidth PLL. However, be aware that the low-bandwidth PLL also increases lock time.
- After a switchover occurs, there may be a finite resynchronization period for the PLL to lock onto a new clock. The time it takes for the PLL to relock depends on the PLL configuration.
- The phase relationship between the input clock to the PLL and the output clock from the PLL is important in your design. Assert `areset` for at least 10 ns after performing a clock switchover. Wait for the locked signal to go high and be stable before re-enabling the output clocks from the PLL.
- The VCO frequency gradually decreases when the current clock is lost and then increases as the VCO locks on to the backup clock, as shown in the following figure.

Document Revision History

Date	Version	Changes
January 2015	2015.01.23	• Added a note pointing to `FRACTIONALPLL_X183_Y63` and `FRACTIONALPLL_X183_Y54` in PLL locations diagram for Arria V SX B3 and B5 Devices, and Arria V ST D3 and D5 Devices. Note: `CLK10` and `CLK11` clock pins feed into `FRACTIONALPLL_X183_Y63` and `FRACTIONALPLL_X183_Y54`. • PLL coordinates for Arria V GT C3 and C7 devices are finalized. Removed the notes that state the PLL coordinates will be finalized in a future release of the Quartus II software from the PLL locations diagrams.

Date	Version	Changes
January 2014	2014.01.10	• Removed Preliminary tags for clock resources, clock input pin connections to GCLK and RCLK networks, and PLL features tables. • Updated clock resources table. • Added availability for RCLK[46..51] and RCLK[52..57] pins in RCLK networks diagram. • Added notes to dedicated clock input pin connectivity to GCLK and RCLK tables. • Added label for PLL strip in PLL locations diagrams. • Added descriptions for PLLs located in a strip. • Added PLL locations diagram for Arria V SX B3 and B5 devices, and Arria V ST D3 and D5 devices. • Added information on PLL migration guidelines. • Updated VCO post-scale counter, K, to VCO post divider. • Added information on PLL cascading. • Added information on programmable phase shift. • Updated automatic clock switchover mode requirement.
May 2013	2013.05.06	• Added link to the known document issues in the Knowledge Base. • Updated RCLK and PCLK clock sources per device quadrant. • Added link to Arria V GZ Device Family Pin Connection Guidelines. • Updated RCLK and PCLK clock sources in hierarchical clock networks in each spine clock per quadrant diagram. • Added PCLK networks in clock network sources section. • Updated dedicated clock input pins in clock network sources section. • Updated information on clock power down. • Added information on C output counters for PLLs. • Added power down mode in PLL features table. • Added PLL physical counters information and diagram. • Marked PLL physical counters orientation in PLL locations diagrams. • Updated the fractional PLL architecture diagram to add dedicated refclk input port and connections. • Removed information on pfdena PLL control signal. • Updated the scaling factors for PLL output ports. • Updated the fractional value for PLL in fractional mode. • Moved all links to the Related Information section of respective topics for easy reference. • Reorganized content.

Date	Version	Changes
November 2012	2012.11.19	• Added note to indicate that the figures shown are the top view of the silicon die. • Updated clock resources for Arria V GZ devices. • Added RCLK networks diagram for Arria V GZ devices. • Restructured tables for clock input pin connectivity to the GCLK and RCLK networks. • Added table for clock input pin connectivity to the RCLK networks for Arria V GZ devices. • Updated PCLK control block information. • Added PLL locations diagrams for Arria V GZ E1, E3, E5, and E7 devices. • Removed information on PLL Compensation assignment in the Quartus II software. • Updated the fractional value for PLL in fractional mode. • Reorganized content and updated template.
June 2012	2.0	• Restructured chapter. • Updated Figure 4–4, Figure 4–6, Figure 4–7, Figure 4–11, Figure 4–12, Figure 4–13, Figure 4–14, Figure 4–15, Figure 4–16, Figure 4–18, and Figure 4–19. • Updated Table 4–1, Table 4–2, Table 4–3, Table 4–4, and Table 4–5. • Added “Clock Regions”, “Clock Network Sources”, “Clock Output Connections”, “Clock Enable Signals”, “PLL Control Signals”, “Clock Multiplication and Division”, “Programmable Duty Cycle”, “Clock Switchover”, and “PLL Reconfiguration and Dynamic Phase Shift”.
November 2011	1.1	Restructured chapter.
May 2011	1.0	Initial release.

I/O Features in Arria V Devices

5

2015.01.23

AV-52005

This chapter provides details about the features of the Arria V I/O elements (IOEs) and how the IOEs work in compliance with current and emerging I/O standards and requirements.

The Arria V I/Os support the following features:

- Single-ended, non-voltage-referenced, and voltage-referenced I/O standards
- Low-voltage differential signaling (LVDS), RSDS, mini-LVDS, HSTL, HSUL, and SSTL I/O standards
- Serializer/deserializer (SERDES)
- Programmable output current strength
- Programmable slew-rate
- Programmable bus-hold
- Programmable pull-up resistor
- Programmable pre-emphasis
- Programmable I/O delay
- Programmable voltage output differential (V_{OD})
- Open-drain output
- On-chip series termination (R_S OCT) with and without calibration
- On-chip parallel termination (R_T OCT)
- On-chip differential termination (R_D OCT)

Note: The information in this chapter is applicable to all Arria V variants, unless noted otherwise.

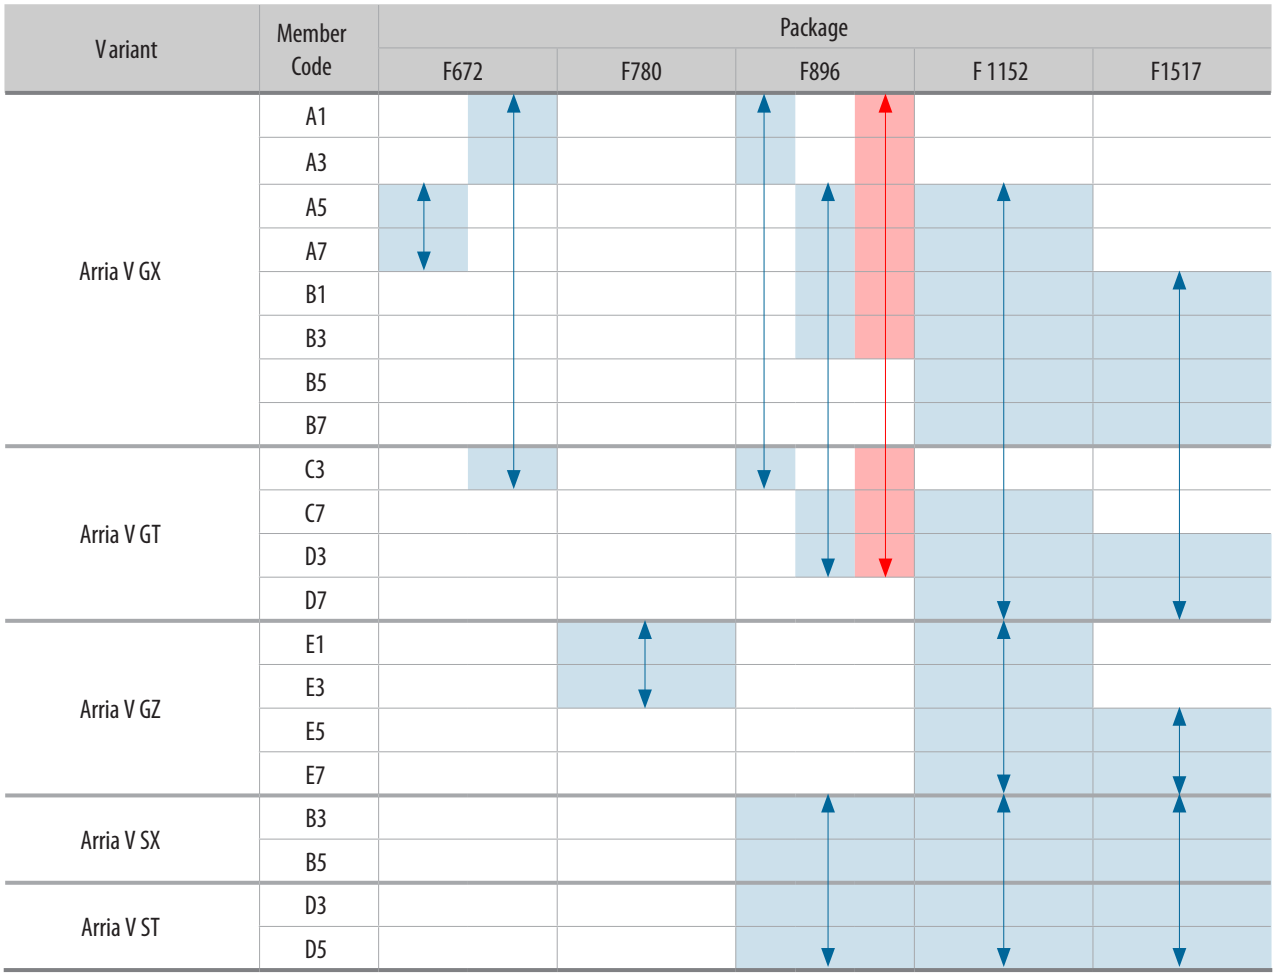
I/O Vertical Migration for Arria V Devices

Figure 5-1: Vertical Migration Capability Across Arria V Device Packages and Densities

The arrows indicate the vertical migration paths. Some packages have several migration paths. The devices included in each vertical migration path are shaded. You can also migrate your design across device densities in the same package option if the devices have the same dedicated pins, configuration pins, and power pins.



You can achieve the vertical migration shaded in red if you use only up to 320 GPIOs, up to nine 6 Gbps transceiver channels, and up to four 10 Gbps transceiver (for Arria V GT devices). This migration path is not shown in the Quartus II software Pin Migration View.

Note: To verify the pin migration compatibility, use the Pin Migration View window in the Quartus II software Pin Planner.

Note: Except for Arria V GX A5 and A7, and Arria V GT C7 devices, all other Arria V GX and GT devices require a specific power-up sequence. If you plan to migrate your design from Arria V GX A5 and A7, and Arria V GT C7 devices to other Arria V devices, your design must adhere to the same required power-up sequence.

Related Information

- **Arria V GX, GT, SX, and ST Power-Up Sequence** on page 11-7

- **I/O Management chapter, Quartus II Handbook**
  Provides more information about vertical I/O migrations.
- **What is the difference between pin-to-pin compatibility and drop-in compatibility?**

Verifying Pin Migration Compatibility

You can use the **Pin Migration View** window in the Quartus II software Pin Planner to assist you in verifying whether your pin assignments migrate to a different device successfully. You can vertically migrate to a device with a different density while using the same device package, or migrate between packages with different densities and ball counts.

1. Open **Assignments** > **Pin Planner** and create pin assignments.
2. If necessary, perform one of the following options to populate the Pin Planner with the node names in the design:
   - Analysis & Elaboration
   - Analysis & Synthesis
   - Fully compile the design
3. Then, on the menu, click **View** > **Pin Migration View**.
4. To select or change migration devices:
   a. Click **Device** to open the **Device** dialog box.
   b. Under **Migration compatibility** click **Migration Devices**.
5. To show more information about the pins:
   a. Right-click anywhere in the **Pin Migration View** window and select **Show Columns**.
   b. Then, click the pin feature you want to display.
6. If you want to view only the pins, in at least one migration device, that have a different feature than the corresponding pin in the migration result, turn on **Show migration differences**.
7. Click **Pin Finder** to open the **Pin Finder** dialog box and find and highlight pins with specific functionality.
   If you want to view only the pins found and highlighted by the most recent query in the **Pin Finder** dialog box, turn on **Show only highlighted pins**.
8. To export the pin migration information to a Comma-Separated Value File (**.csv**), click **Export**.

MultiVolt I/O Interface in Arria V Devices

The MultiVolt I/O interface feature allows Arria V devices in all packages to interface with systems of different supply voltages.

Table 5-9: MultiVolt I/O Support in Arria V Devices

V_{CCIO} (V)	Device Variant Support	V_{CCPD} (V)	Input Signal (V)	Output Signal (V)
1.2	All	2.5	1.2	1.2
1.25	All	2.5	1.25	1.25
1.35	All	2.5	1.35	1.35
1.5	All	2.5	1.5, 1.8	1.5
1.8	All	2.5	1.5, 1.8	1.8
2.5	All	2.5	2.5, 3.0, 3.3	2.5

(12) You cannot assign SSTL, HSTL, and HSUL outputs on VREF pins, even if there are no SSTL, HSTL, and HSUL inputs in the bank.
(13) Input buffers for the SSTL, HSTL, Differential SSTL, Differential HSTL, LVDS, RSDS, Mini-LVDS, LVPECL, HSUL, and Differential HSUL are powered by V_{CCPD}
(14) Single-ended I/O standard at this voltage is not supported in the Arria V devices. This information highlights that multiple single-ended I/O standards are not compatible with V_{CCIO} at this voltage.

V_{CCIO} (V)	Device Variant Support	V_{CCPD} (V)	Input Signal (V)	Output Signal (V)
3.0	GX, GT, SX, and ST	3.0	2.5, 3.0, 3.3	3.0
	GZ	3.0	2.5, 3.0, 3.3	3.0, 3.3
3.3	GX, GT, SX, and ST	3.3	2.5, 3.0, 3.3	3.3

The pin current may be slightly higher than the default value. Verify that the V_{OL} maximum and V_{OH} minimum voltages of the driving device do not violate the applicable V_{IL} maximum and V_{IH} minimum voltage specifications of the Arria V device.

The V_{CCPD} power pins must be connected to a 2.5 V, 3.0 V, or 3.3 V power supply. Using these power pins to supply the pre-driver power to the output buffers increases the performance of the output pins.

Note: If the input signal is 3.0 V or 3.3 V, Altera recommends that you use a clamping diode on the I/O pins. Use the on-chip clamping diode for the Arria V GX, GT, SX, and ST devices, and an external clamping diode for the Arria V GZ devices.

I/O Design Guidelines for Arria V Devices

There are several considerations that require your attention to ensure the success of your designs. Unless noted otherwise, these design guidelines apply to all variants of this device family.

Mixing Voltage-Referenced and Non-Voltage-Referenced I/O Standards

Each I/O bank can simultaneously support multiple I/O standards. The following sections provide guidelines for mixing non-voltage-referenced and voltage-referenced I/O standards in the devices.

Non-Voltage-Referenced I/O Standards

Each Arria V I/O bank has its own V_{CCIO} pins and supports only one V_{CCIO} of 1.2, 1.25, 1.35, 1.5, 1.8, 2.5, 3.0, or 3.3 V[15]. An I/O bank can simultaneously support any number of input signals with different I/O standard assignments if the I/O standards support the V_{CCIO} level of the I/O bank.

For output signals, a single I/O bank supports non-voltage-referenced output signals that drive at the same voltage as V_{CCIO}. Because an I/O bank can only have one V_{CCIO} value, it can only drive out the value for non-voltage-referenced signals.

For example, an I/O bank with a 2.5 V V_{CCIO} setting can support 2.5 V standard inputs and outputs, and 3.0 V LVCMOS inputs only.

Voltage-Referenced I/O Standards

To accommodate voltage-referenced I/O standards:

- Each Arria V GX, GT, SX, or ST I/O bank contains a dedicated VREF pin.
- Each Arria V GZ I/O bank supports multiple dedicated VREF pins feeding a common V_{REF} bus.
- Each bank can have only a single V_{CCIO} voltage level and a single voltage reference (V_{REF}) level.

[15] Arria V GZ devices do not support 3.3 V

An I/O bank featuring single-ended or differential standards can support different voltage-referenced standards if the V_{CCIO} and V_{REF} are the same levels.

For performance reasons, voltage-referenced input standards use their own V_{CCPD} level as the power source. This feature allows you to place voltage-referenced input signals in an I/O bank with a V_{CCIO} of 2.5 V or below. For example, you can place HSTL-15 input pins in an I/O bank with 2.5 V V_{CCIO}. However, the voltage-referenced input with R_T OCT enabled requires the V_{CCIO} of the I/O bank to match the voltage of the input standard. R_T OCT cannot be supported for the HSTL-15 I/O standard when V_{CCIO} is 2.5 V.

Voltage-referenced bidirectional and output signals must be the same as the V_{CCIO} voltage of the I/O bank. For example, you can place only SSTL-2 output pins in an I/O bank with a 2.5 V V_{CCIO}.

Mixing Voltage-Referenced and Non-Voltage Referenced I/O Standards

An I/O bank can support voltage-referenced and non-voltage-referenced pins by applying each of the rule sets individually.

Examples:

- An I/O bank can support SSTL-18 inputs and outputs, and 1.8 V inputs and outputs with a 1.8 V V_{CCIO} and a 0.9 V V_{REF}.
- An I/O bank can support 1.5 V standards, 1.8 V inputs (but not outputs), and 1.5 V HSTL I/O standards with a 1.5 V V_{CCIO} and 0.75 V V_{REF}.

Guideline: Use the Same V_{CCPD} for All I/O Banks in a Group

One V_{CCPD} is shared in a group of I/O banks. If one I/O bank in a group uses 3.0 V V_{CCPD}, other I/O banks in the same group must also use 3.0 V V_{CCPD}.

The I/O banks with the same bank number form a group. For example, I/O banks 8A, 8B, 8C, and 8D form a group and share the same V_{CCPD}. This sharing is applicable to all I/O banks, with the following exceptions:

- Arria V GX and GT devices—No V_{CCPD} sharing in bank 4A and 7A. Each of these I/O banks has their own individual V_{CCPD}.
- Arria V SX and ST devices—No V_{CCPD} sharing in bank 4A. In these devices, banks 6A, 6B, and 7A through 7E are HPS I/O banks.
- Arria V GZ devices—No V_{CCPD} sharing across banks 3A, 3B, 3C, and 3D. Banks 3A and 3B form a group with one V_{CCPD} while bank 3C (if available) and 3D form another group with its own V_{CCPD}.

For the Arria V GZ devices, if you are using an output or bidirectional pin with the 3.3 V LVTTL or 3.3 V LVCMOS I/O standard, you must adhere to this restriction manually with location assignments.

For more information about the I/O banks available in each device package, refer to the related information.

Guideline: Ensure Compatible V_{CCIO} and V_{CCPD} Voltage in the Same Bank

When planning I/O bank usage for Arria V GX, GT, SX, and ST devices, you must ensure the V_{CCIO} voltage is compatible with the V_{CCPD} voltage of the same bank. Some banks may share the same V_{CCPD} power pin. This limits the possible V_{CCIO} voltages that can be used on banks that share VCCPD power pins.

Examples:

- VCCPD4BCD is connected to 2.5 V—VCCIO pins for banks 4B, 4C, and 4D can be connected 1.2 V, 1.25 V, 1.35 V, 1.5 V, 1.8 V, or 2.5 V.
- VCCPD4BCD is connected to 3.0 V—VCCIO pins for banks 4B, 4C, and 4D must be connected to 3.0 V.

Guideline: VREF Pin Restrictions

For the Arria V GX, GT, SX, and ST devices, consider the following VREF pins guidelines:

- You cannot assign shared VREF pins as LVDS or external memory interface pins.
- SSTL, HSTL, and HSUL I/O standards do not support shared VREF pins. For example, if a particular B1p or B1n pin is a shared VREF pin, the corresponding B1p/B1n pin pair do not have LVDS transmitter support.
- Shared VREF pins will have reduced performance when used as normal I/Os.
- You must perform signal integrity analysis using your board design when using a shared VREF pin to determine the F_{MAX} for your system.

For more information about pin capacitance of the VREF pins, refer to the device datasheet.

Guideline: Observe Device Absolute Maximum Rating for 3.3 V Interfacing

To ensure device reliability and proper operation when you use the device for 3.3 V I/O interfacing, do not violate the absolute maximum ratings of the device. For more information about absolute maximum rating and maximum allowed overshoot during transitions, refer to the device datasheet.

Tip: Perform IBIS or SPICE simulations to make sure the overshoot and undershoot voltages are within the specifications.

Transmitter Application

If you use the Arria V device as a transmitter, use slow slew-rate and series termination to limit the overshoot and undershoot at the I/O pins. Transmission line effects that cause large voltage deviations at the receiver are associated with an impedance mismatch between the driver and the transmission lines. By matching the impedance of the driver to the characteristic impedance of the transmission line, you can significantly reduce overshoot voltage. You can use a series termination resistor placed physically close to the driver to match the total driver impedance to the transmission line impedance.

Receiver Application

If you use the Arria V device as a receiver, to limit the overshoot and undershoot voltage at the I/O pins:

- Arria V GX, GT, SX, or ST—use the on-chip clamping diode.
- Arria V GZ device—use an off-chip clamping diode.

The 3.3 V I/O standard is supported using the bank supply voltage (V_{CCIO}) at 3.0 V and a V_{CCPD} voltage of 3.0 V. In this method, the clamping diode can sufficiently clamp overshoot voltage to within the DC and AC input voltage specifications. The clamped voltage is expressed as the sum of the V_{CCIO} and the diode forward voltage.

Guideline: Use PLL Integer Mode for LVDS Applications

For LVDS applications, you must use the phase-locked loops (PLLs) in integer PLL mode.

Related Information

Guideline: Use PLLs in Integer PLL Mode for LVDS on page 6-7

Guideline: Pin Placement for General Purpose High-Speed Signals

For general purpose high-speed signals faster than 200 MHz, follow these guidelines to ensure I/O timing closure.

- Avoid using HMC DQ pins as the input pin.
- Avoid using HMC DQ and command pins as the output pin.

I/O signals that use the hard memory controller pins are routed through the `HMCPHY_RE` routing elements. These routing elements have a higher routing delay compared to other I/O pins. To identify the hard memory controller pins for your Arria V device and package, refer to the relevant pin-out files.

I/O Banks Groups in Arria V Devices

The I/O pins in Arria V devices are arranged in groups called modular I/O banks:

- Modular I/O banks have independent power supplies that allow each bank to support different I/O standards.
- Each modular I/O bank can support multiple I/O standards that use the same V_{CCIO} and V_{CCPD} voltages.

I/O Element Structure in Arria V Devices

The I/O elements (IOEs) in Arria V devices contain a bidirectional I/O buffer and I/O registers to support a complete embedded bidirectional single data rate (SDR) or double data rate (DDR) transfer.

The IOEs are located in I/O blocks around the periphery of the Arria V device.

The Arria V SX and ST devices also have I/O elements for the HPS.

I/O Buffer and Registers in Arria V Devices

I/O registers are composed of the input path for handling data from the pin to the core, the output path for handling data from the core to the pin, and the output enable (OE) path for handling the OE signal to the output buffer. These registers allow faster source-synchronous register-to-register transfers and resynchronization.

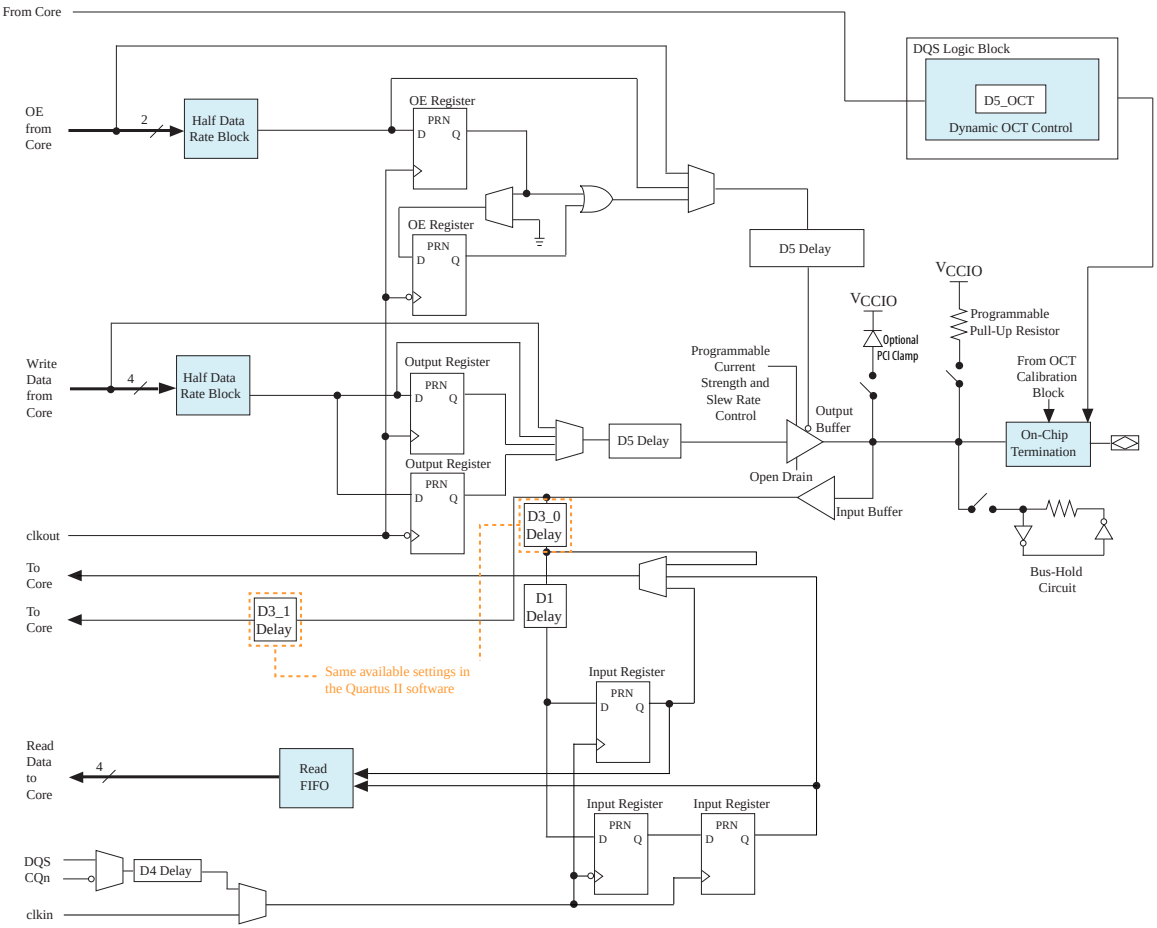
Table 5-16: Input and Output Paths in Arria V Devices

This table summarizes the input and output path in the Arria V devices.

Input Path	Output Path
Consists of: • DDR input registers • Alignment and synchronization registers • Half data rate blocks	Consists of: • Output or OE registers • Alignment registers • Half data rate blocks
You can bypass each block in the input path. The input path uses the deskew delay to adjust the input register clock delay across process, voltage, and temperature (PVT) variations.	You can bypass each block of the output and OE paths.

Figure 5-5: IOE Structure for Arria V Devices

This figure shows the Arria V FPGA IOE structure. In the figure, one dynamic on-chip termination (OCT) control is available for each DQ/DQS group.



Programmable IOE Features in Arria V Devices

Table 5-17: Summary of Supported Arria V Programmable IOE Features and Settings

Feature	Setting (Default setting in bold)	Condition	Supported in HPS I/O (SoC Devices Only)
Slew Rate Control	0 (Slow), 1 (Fast). Default is 1.	Disabled if you use the R_S OCT feature.	Yes
I/O Delay	Refer to the device datasheet	—	—
Open-Drain Output	On, Off (default)	—	Yes

Feature	Setting (Default setting in bold)	Condition	Supported in HPS I/O (SoC Devices Only)
Bus-Hold	On, Off (default)	Disabled if you use the weak pull-up resistor feature.	Yes
Weak Pull-up Resistor	On, Off (default)	Disabled if you use the bus-hold feature.	Yes
Pre-Emphasis	0 (disabled), 1 (enabled). Default is 1.	—	—
Differential Output Voltage	• Arria V GX, GT, SX, and ST—0 (low), 1 (medium), 2 (high). Default is 1. • Arria V GZ—0 (low), 1 (medium low), 2 (medium high), 3 (high). Default is 1.	—	—
On-Chip Clamp Diode (GX, GT, SX, and ST only)	On, Off (default)	—	Yes

Note: The on-chip clamp diode is available on all general purpose I/O (GPIO) pins in the Arria V GX, GT, SX, and ST device variants.

Programmable Current Strength

You can use the programmable current strength to mitigate the effects of high signal attenuation that is caused by a long transmission line or a legacy backplane.

Table 5-18: Programmable Current Strength Settings for Arria V Devices

The output buffer for each Arria V device I/O pin has a programmable current strength control for the I/O standards listed in this table.

I/O Standard	I_{OH} / I_{OL} Current Strength Setting (mA) (Default setting in bold)		Supported in HPS (SoC Devices Only)
	Arria V GX, GT, SX, and ST	Arria V GZ	
3.3-V LVTTL	**8** , 4	16, **12** , 8, 4	Yes
3.3-V LVCMOS	**2**	16, **12** , 8, 4	Yes
3.0-V LVTTL	16, **12** , 8, 4	—	Yes
3.0-V LVCMOS	16, **12** , 8, 4	—	Yes
2.5-V LVCMOS	16, **12** , 8, 4	16, **12** , 8, 4	Yes
1.8-V LVCMOS	**12** , 10, 8, 6, 4, 2	**12** , 10, 8, 6, 4, 2	Yes
1.5-V LVCMOS	**12** , 10, 8, 6, 4, 2	**12** , 10, 8, 6, 4, 2	Yes
1.2-V LVCMOS	**8** , 6, 4, 2	**8** , 6, 4, 2	—
SSTL-2 Class I	12, 10, **8**	12, 10, **8**	—
SSTL-2 Class II	**16**	**16**	—
SSTL-18 Class I	12, 10, **8** , 6, 4	12, 10, **8** , 6, 4	Yes
SSTL-18 Class II	**16**	**16** , 8	Yes
SSTL-15 Class I	12, 10, **8** , 6, 4	12, 10, **8** , 6, 4	Yes
SSTL-15 Class II	**16**	**16** , 8	Yes
1.8-V HSTL Class I	12, 10, **8** , 6, 4	12, 10, **8** , 6, 4	—
1.8-V HSTL Class II	**16**	**16**	—
1.5-V HSTL Class I	12, 10, **8** , 6, 4	12, 10, **8** , 6, 4	Yes
1.5-V HSTL Class II	**16**	**16**	Yes
1.2-V HSTL Class I	12, 10, **8** , 6, 4	12, 10, **8** , 6, 4	—
1.2-V HSTL Class II	**16**	**16**	—

For the Arria V GZ devices, the 3.3 V LVTTL and 3.3 V LVCMOS I/O standards are supported using V_{CCIO} and V_{CCPD} at 3.0 V .

Note: Altera recommends that you perform IBIS or SPICE simulations to determine the best current strength setting for your specific application.

Programmable IOE Features in Arria V Devices on page 5-25

Programmable Output Slew-Rate Control

Programmable output slew-rate is available for single-ended I/O standards and emulated LVDS output standards.

The programmable output slew-rate control in the output buffer of each regular- and dual-function I/O pin allows you to configure the following:

- Fast slew-rate—provides high-speed transitions for high-performance systems.
- Slow slew-rate—reduces system noise and crosstalk but adds a nominal delay to the rising and falling edges.

You can specify the slew-rate on a pin-by-pin basis because each I/O pin contains a slew-rate control.

Note: Altera recommends that you perform IBIS or SPICE simulations to determine the best slew rate setting for your specific application.

Related Information

Programmable IOE Features in Arria V Devices on page 5-25

Programmable IOE Delay

You can activate the programmable IOE delays to ensure zero hold times, minimize setup times, or increase clock-to-output times. This feature helps read and write timing margins because it minimizes the uncertainties between signals in the bus.

Each pin can have a different input delay from pin-to-input register or a delay from output register-to-output pin values to ensure that the signals within a bus have the same delay going into or out of the device.

For more information about the programmable IOE delay specifications, refer to the device datasheet.

Related Information

- **Arria V Device Datasheet**
- **Programmable IOE Features in Arria V Devices** on page 5-25

Programmable Output Buffer Delay

The delay chains are built inside the single-ended output buffer. There are four levels of output buffer delay settings. By default, there is no delay.

The delay chains can independently control the rising and falling edge delays of the output buffer, allowing you to:

- Adjust the output-buffer duty cycle
- Compensate channel-to-channel skew
- Reduce simultaneous switching output (SSO) noise by deliberately introducing channel-to-channel skew
- Improve high-speed memory-interface timing margins

For more information about the programmable output buffer delay specifications, refer to the device datasheet.

Programmable Pre-Emphasis

The V_{OD} setting and the output impedance of the driver set the output current limit of a high-speed transmission signal. At a high frequency, the slew rate may not be fast enough to reach the full V_{OD} level before the next edge, producing pattern-dependent jitter. With pre-emphasis, the output current is boosted momentarily during switching to increase the output slew rate.

Pre-emphasis increases the amplitude of the high-frequency component of the output signal, and thus helps to compensate for the frequency-dependent attenuation along the transmission line. The overshoot introduced by the extra current happens only during a change of state switching to increase the output slew rate and does not ring, unlike the overshoot caused by signal reflection. The amount of pre-emphasis required depends on the attenuation of the high-frequency component along the transmission line.

Figure 5-6: Programmable Pre-Emphasis

This figure shows the LVDS output with pre-emphasis.

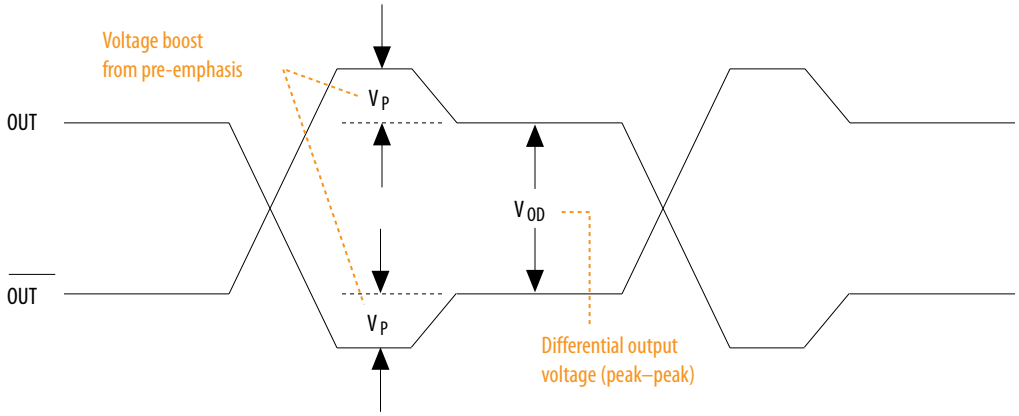

Table 5-19: Quartus II Software Assignment Editor—Programmable Pre-Emphasis

This table lists the assignment name for programmable pre-emphasis and its possible values in the Quartus II software Assignment Editor.

Field	Assignment
To	`tx_out`
Assignment name	Programmable Pre-emphasis
Allowed values	0 (disabled), 1 (enabled). Default is 1.

Related Information

Programmable IOE Features in Arria V Devices on page 5-25

Programmable Differential Output Voltage

The programmable V_{OD} settings allow you to adjust the output eye opening to optimize the trace length and power consumption. A higher V_{OD} swing improves voltage margins at the receiver end, and a smaller V_{OD} swing reduces power consumption. You can statically adjust the V_{OD} of the differential signal by changing the V_{OD} settings in the Quartus II software Assignment Editor.

Figure 5-7: Differential V_{OD}

This figure shows the V_{OD} of the differential LVDS output.

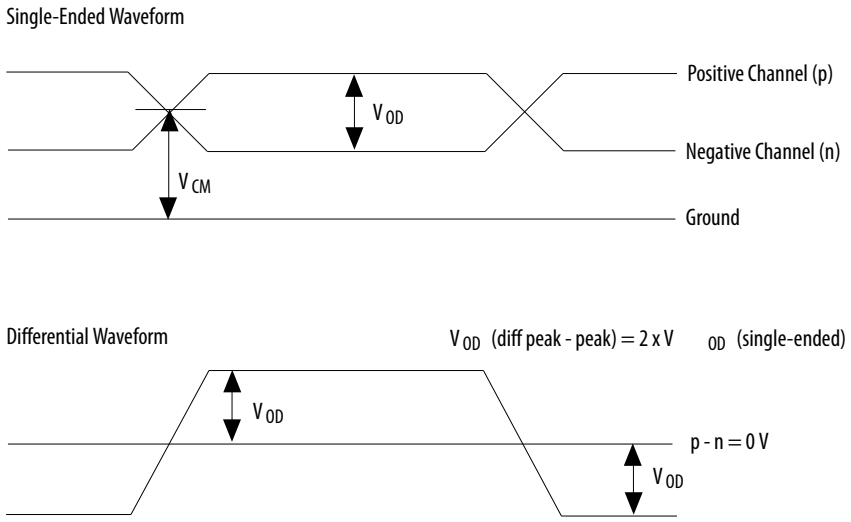

Table 5-20: Quartus II Software Assignment Editor—Programmable V_{OD}

This table lists the assignment name for programmable V_{OD} and its possible values in the Quartus II software Assignment Editor.

Field	Assignment
To	`tx_out`
Assignment name	Programmable Differential Output Voltage (V_{OD})
Allowed values	• Arria V GX, GT, SX, and ST—0 (low), 1 (medium), 2 (high). Default is 1. • Arria V GZ—0 (low), **1** (medium low), 2 (medium high), 3 (high). Default is 1.

Open-Drain Output

The optional open-drain output for each I/O pin is equivalent to an open collector output. If it is configured as an open drain, the logic value of the output is either high-Z or logic low.

You can attach several open-drain output to a wire. This connection type is like a logical OR function and is commonly called an active-low wired-OR circuit. If at least one of the outputs is in logic 0 state (active), the circuit sinks the current and brings the line to low voltage.

You can use open-drain output if you are connecting multiple devices to a bus. For example, you can use the open-drain output for system-level control signals that can be asserted by any device or as an interrupt.

You can enable the open-drain output assignment using one these methods:

- Design the tristate buffer using OPNDRN primitive.
- Turn on the **Auto Open-Drain Pins** option in the Quartus II software.

Although you can design open-drain output without enabling the option assignment, you will not be using the open-drain output feature of the I/O buffer. The open-drain output feature in the I/O buffer provides you the best propagation delay from OE to output.

Pull-up Resistor

Each I/O pin provides an optional programmable pull-up resistor during user mode. The pull-up resistor, typically 25 kΩ, weakly holds the I/O to the V_{CCIO} level. If you enable this option, you cannot use the bus-hold feature.

The Arria V device supports programmable weak pull-up resistors only on user I/O pins.

For dedicated configuration pins, dedicated clock pins, or JTAG pins with internal pull-up resistors, these resistor values are not programmable. You can find more information related to the internal pull-up values for dedicated configuration pins, dedicated clock pins, or JTAG pins in the Arria V Pin Connection Guidelines.

Bus-Hold Circuitry

Each I/O pin provides an optional bus-hold feature that is active only after configuration. When the device enters user mode, the bus-hold circuit captures the value that is present on the pin by the end of the configuration.

The bus-hold circuitry uses a resistor with a nominal resistance (R_{BH}), approximately 7 kΩ, to weakly pull the signal level to the last-driven state of the pin. The bus-hold circuitry holds this pin state until the next input signal is present. Because of this, you do not require an external pull-up or pull-down resistor to hold a signal level when the bus is tri-stated.

For each I/O pin, you can individually specify that the bus-hold circuitry pulls non-driven pins away from the input threshold voltage—where noise can cause unintended high-frequency switching. To prevent over-driving signals, the bus-hold circuitry drives the voltage level of the I/O pin lower than the V_{CCIO} level.

If you enable the bus-hold feature, you cannot use the programmable pull-up option. To configure the I/O pin for differential signals, disable the bus-hold feature.

On-Chip I/O Termination in Arria V Devices

Dynamic R_S and R_T OCT provides I/O impedance matching and termination capabilities. OCT maintains signal quality, saves board space, and reduces external component costs.

The Arria V devices support OCT in all FPGA I/O banks. For the HPS I/Os, the column I/Os do not support OCT.

Table 5-21: OCT Schemes Supported in Arria V Devices

Direction	OCT Schemes	Supported in HPS Row I/Os
Output	R_S OCT with calibration	Yes
	R_S OCT without calibration	Yes
Input	R_T OCT with calibration	Yes
	R_D OCT (LVDS I/O standard only)	—
Bidirectional	Dynamic R_S OCT and R_T OCT	Yes

R_S OCT without Calibration in Arria V Devices

The Arria V devices support R_S OCT for single-ended and voltage-referenced I/O standards. R_S OCT without calibration is supported on output only.

Table 5-22: Selectable I/O Standards for R_S OCT Without Calibration

This table lists the output termination settings for uncalibrated OCT on different I/O standards.

I/O Standard	Device Variant Support	Uncalibrated OCT (Output)

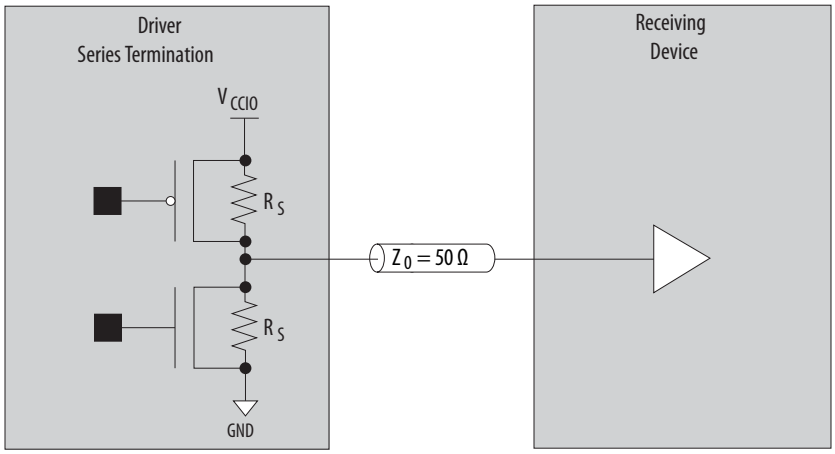
Driver-impedance matching provides the I/O driver with controlled output impedance that closely matches the impedance of the transmission line. As a result, you can significantly reduce signal reflections on PCB traces.

If you select matching impedance, current strength is no longer selectable.

Figure 5-8: R_S OCT Without Calibration

This figure shows the R_S as the intrinsic impedance of the output transistors.



R_S OCT with Calibration in Arria V Devices

The Arria V devices support R_S OCT with calibration in all banks.

Table 5-23: Selectable I/O Standards for R_S OCT With Calibration

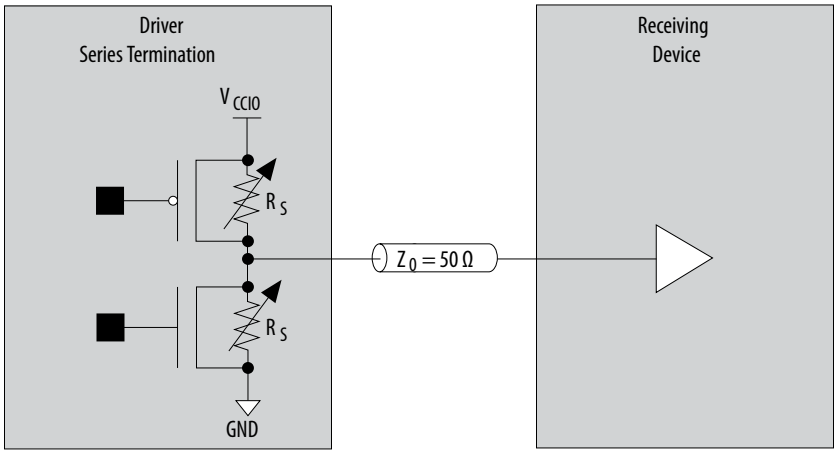
The R_S OCT calibration circuit compares the total impedance of the I/O buffer to the external reference resistor connected to the RZQ pin and dynamically enables or disables the transistors until they match.

Calibration occurs at the end of device configuration. When the calibration circuit finds the correct impedance, the circuit powers down and stops changing the characteristics of the drivers.

Figure 5-9: R_S OCT with Calibration

This figure shows the R_S as the intrinsic impedance of the output transistors.



R_T OCT with Calibration in Arria V Devices

The Arria V devices support R_T OCT with calibration in all banks. R_T OCT with calibration is available only for configuration of input and bidirectional pins. Output pin configurations do not support R_T OCT with calibration. If you use R_T OCT, the V_{CCIO} of the bank must match the I/O standard of the pin where you enable the R_T OCT.

Table 5-24: Selectable I/O Standards for R_T OCT With Calibration

This table lists the input termination settings for calibrated OCT on different I/O standards.

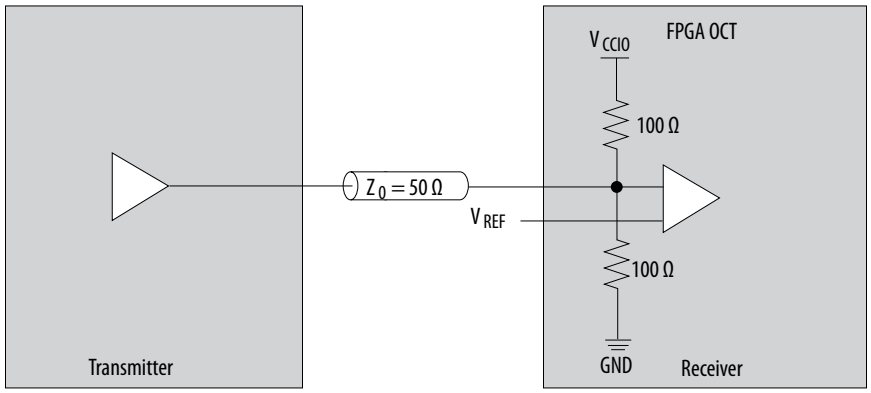
The R_T OCT calibration circuit compares the total impedance of the I/O buffer to the external resistor connected to the RZQ pin. The circuit dynamically enables or disables the transistors until the total impedance of the I/O buffer matches the external resistor.

Calibration occurs at the end of the device configuration. When the calibration circuit finds the correct impedance, the circuit powers down and stops changing the characteristics of the drivers.

Figure 5-10: R_T OCT with Calibration



Dynamic OCT in Arria V Devices

Dynamic OCT is useful for terminating a high-performance bidirectional path by optimizing the signal integrity depending on the direction of the data. Dynamic OCT also helps save power because device termination is internal—termination switches on only during input operation and thus draw less static power.

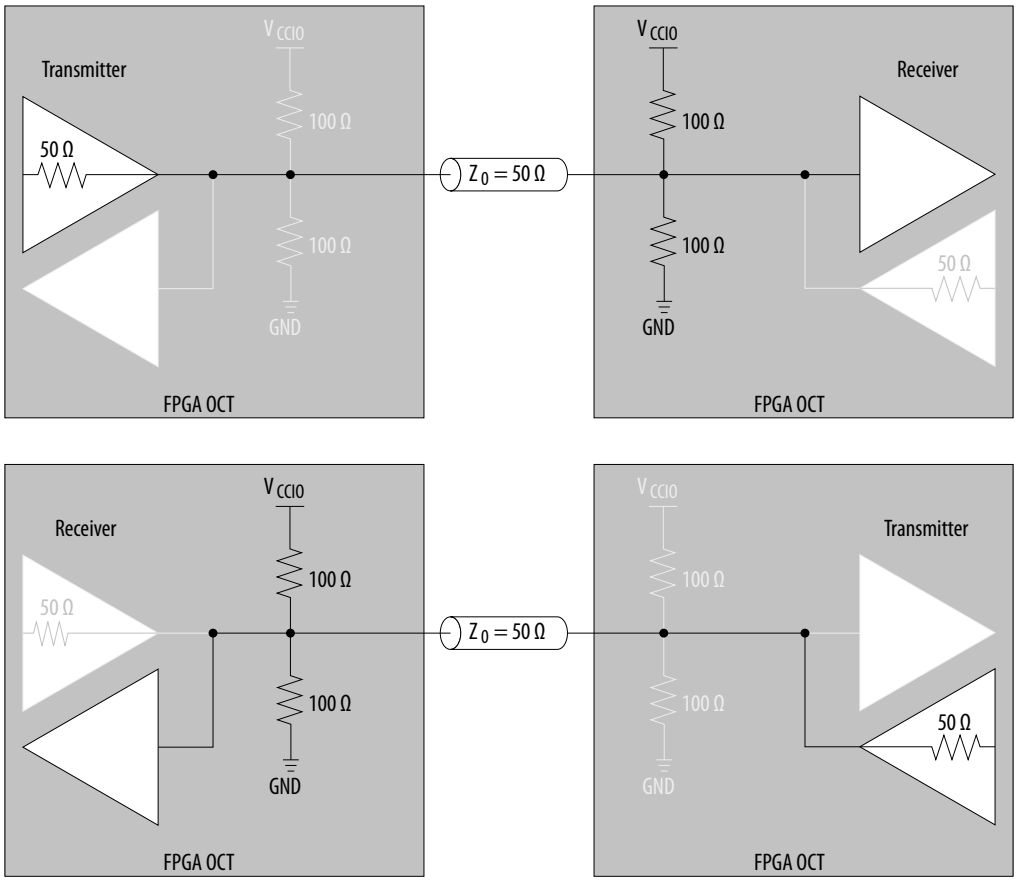
Note: If you use the SSTL-15, SSTL-135, and SSTL-125 I/O standards with the DDR3 memory interface, Altera recommends that you use dynamic OCT with these I/O standards to save board space and cost. Dynamic OCT reduces the number of external termination resistors used.

Table 5-25: Dynamic OCT Based on Bidirectional I/O

Dynamic R_T OCT or R_S OCT is enabled or disabled based on whether the bidirectional I/O acts as a receiver or driver.

Dynamic OCT	Bidirectional I/O	State
Dynamic R_T OCT	Acts as a receiver	Enabled
	Acts as a driver	Disabled
Dynamic R_S OCT	Acts as a receiver	Disabled
	Acts as a driver	Enabled

Figure 5-11: Dynamic R_T OCT in Arria V Devices



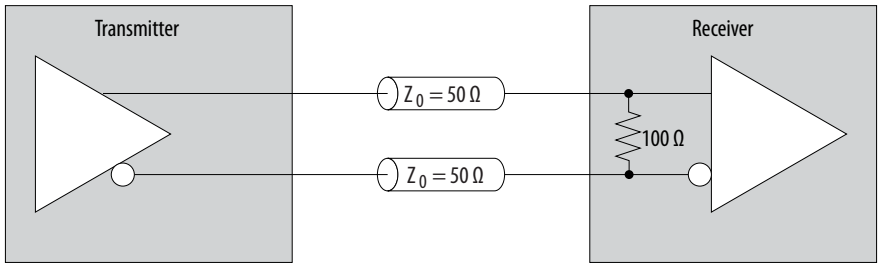
LVDS Input R_D OCT in Arria V Devices

The Arria V devices support R_D OCT in all I/O banks.

You can only use R_D OCT if you set the V_{CCPD} to 2.5 V.

Figure 5-12: Differential Input OCT

The Arria V devices support OCT for differential LVDS input buffers with a nominal resistance value of 100 Ω, as shown in this figure.



OCT Calibration Block in Arria V Devices

You can calibrate the OCT using any of the available four OCT calibration blocks for each device. Each calibration block contains one RZQ pin.

You can use R_S and R_T OCT in the same I/O bank for different I/O standards if the I/O standards use the same V_{CCIO} supply voltage. You cannot configure the R_S OCT and the programmable current strength for the same I/O buffer.

The OCT calibration process uses the RZQ pin that is available in every calibration block in a given I/O bank for series- and parallel-calibrated termination:

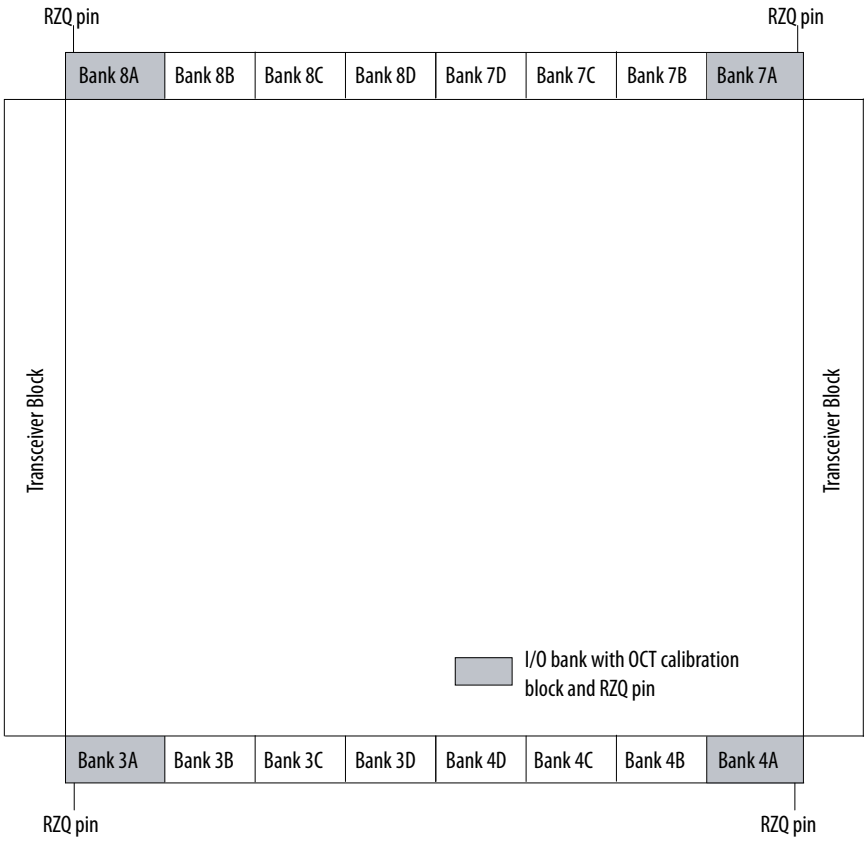
- Connect the RZQ pin to GND through an external 100 Ω or 240 Ω resistor (depending on the R_S or R_T OCT value).
- The RZQ pin shares the same V_{CCIO} supply voltage with the I/O bank where the pin is located.

Arria V devices support calibrated R_S and calibrated R_T OCT on all I/O pins except for dedicated configuration pins.

Calibration Block Locations in Arria V Devices

Figure 5-13: OCT Calibration Block and RZQ Pin Location

This figure shows the location of I/O banks with OCT calibration blocks and RZQ pins in the Arria V device. This figure represents the top view of the silicon die that corresponds to a reverse view of the device package and illustrates the highest density device in the device family.



Sharing an OCT Calibration Block on Multiple I/O Banks

An OCT calibration block has the same V_{CCIO} as the I/O bank that contains the block. All I/O banks with the same V_{CCIO} can share one OCT calibration block, even if that particular I/O bank has an OCT calibration block.

I/O banks that do not have calibration blocks share the calibration blocks in the I/O banks that have calibration blocks.

All I/O banks support OCT calibration with different V_{CCIO} voltage standards, up to the number of available OCT calibration blocks.

You can configure the I/O banks to receive calibration codes from any OCT calibration block with the same V_{CCIO}. If a group of I/O banks has the same V_{CCIO} voltage, you can use one OCT calibration block to calibrate the group of I/O banks placed around the periphery.

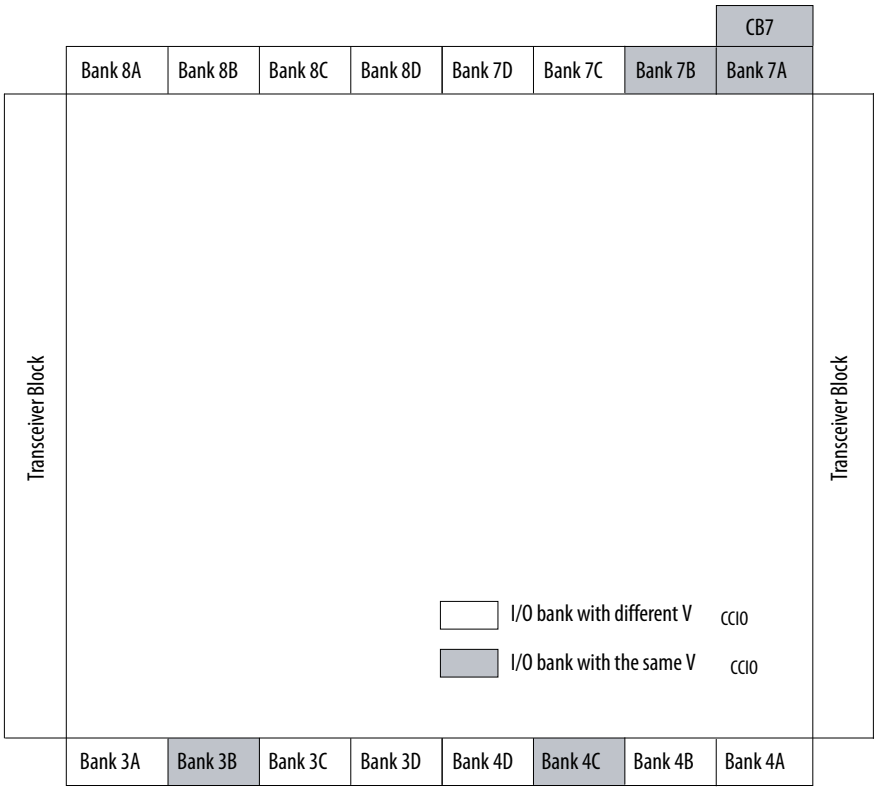
  Provides more information about the OCT calibration block.

OCT Calibration Block Sharing Example

Figure 5-14: Example of Calibrating Multiple I/O Banks with One Shared OCT Calibration Block

As an example, this figure shows a group of I/O banks that has the same V_{CCIO} voltage. The figure does not show transceiver calibration blocks. This figure represents the top view of the silicon die that corresponds to a reverse view of the device package and illustrates the highest density device in the device family.



Because banks 3B, 4C, and 7B have the same V_{CCIO} as bank 7A, you can calibrate all four I/O banks (3B, 4C, 7A, and 7B) with the OCT calibration block (CB7) located in bank 7A.

To enable this calibration, serially shift out the R_S OCT calibration codes from the OCT calibration block in bank 7A to the I/O banks around the periphery.

Single-ended I/O Termination

Voltage-referenced I/O standards require an input V_{REF} and a termination voltage (V_{TT}). The reference voltage of the receiving device tracks the termination voltage of the transmitting device.

The supported I/O standards such as SSTL-12, SSTL-125, SSTL-135, and SSTL-15 typically do not require external board termination.

Altera recommends that you use dynamic OCT with these I/O standards to save board space and cost. Dynamic OCT reduces the number of external termination resistors used.

Note: You cannot use R_S and R_T OCT simultaneously. For more information, refer to the related information.

(16) Altera recommends that you use dynamic OCT with these I/O standards to save board space and cost. Dynamic OCT reduces the number of external termination resistors used.

Figure 5-15: SSTL I/O Standard Termination

This figure shows the details of SSTL I/O termination on Arria V devices.

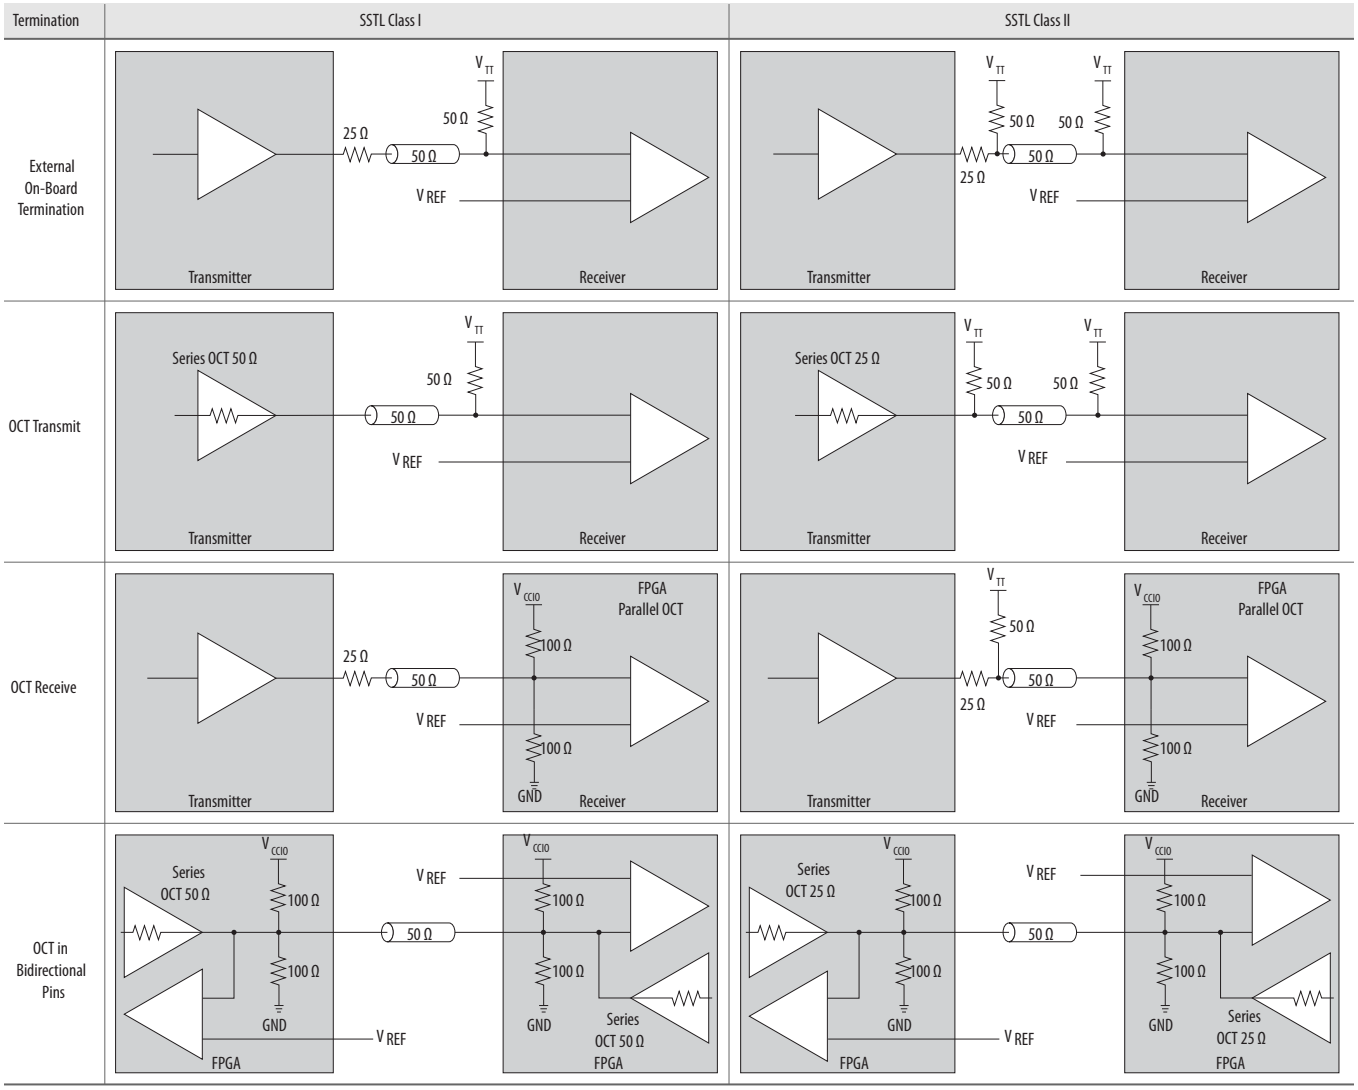

Figure 5-16: HSTL I/O Standard Termination

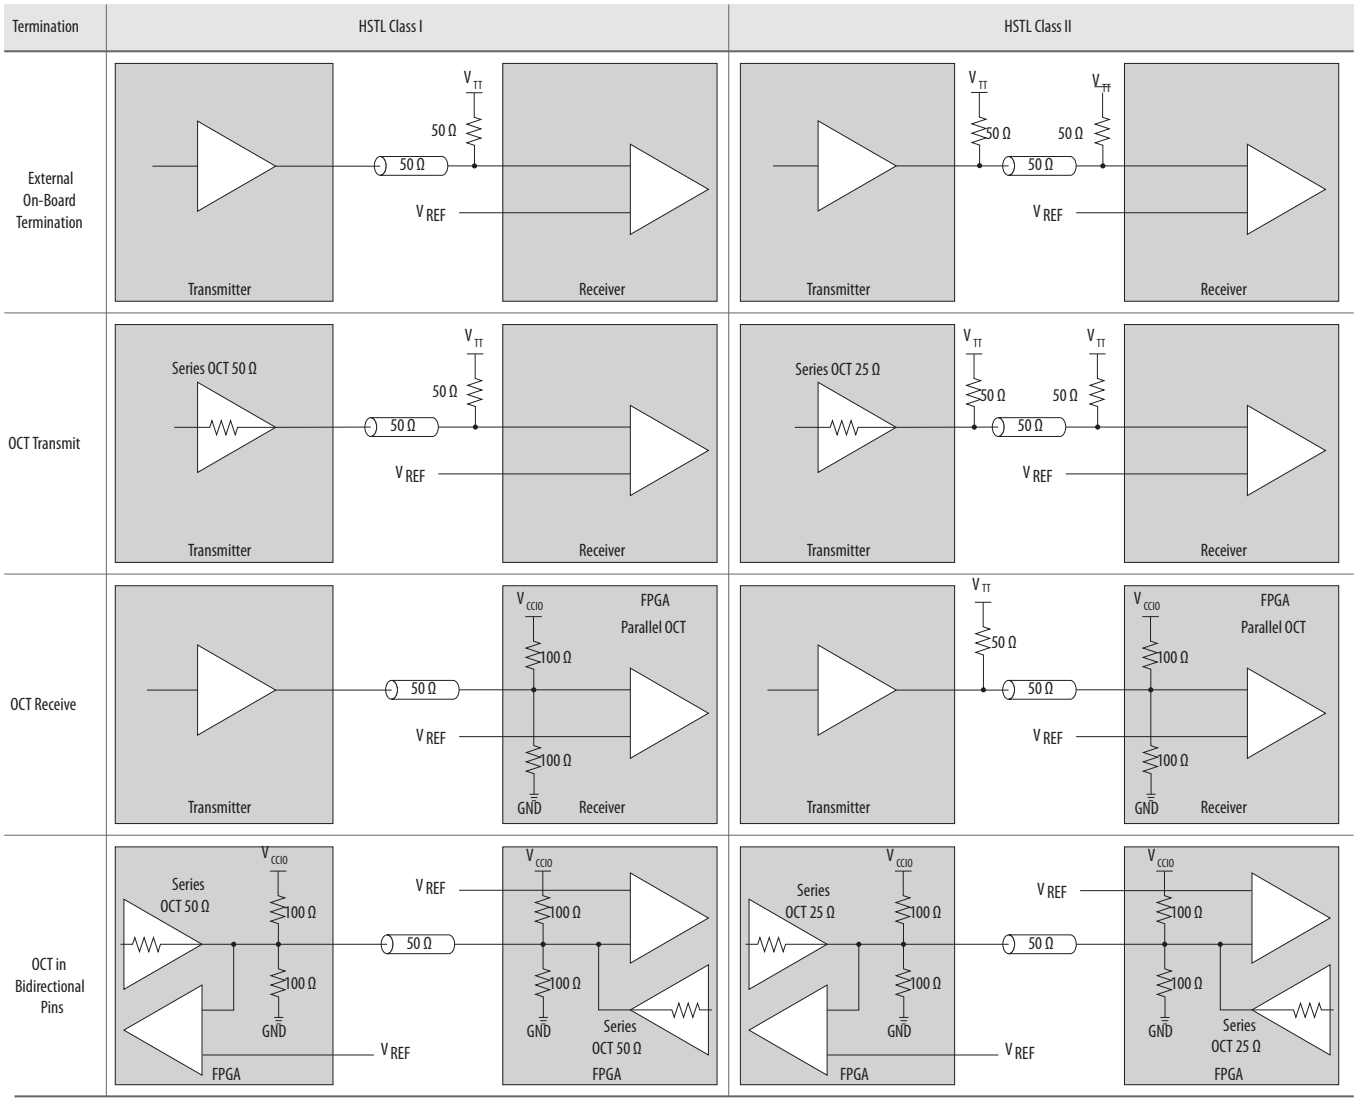
This figure shows the details of HSTL I/O termination on the Arria V devices.



Related Information

Dynamic OCT in Arria V Devices on page 5-38

Differential I/O Termination

The I/O pins are organized in pairs to support differential I/O standards. Each I/O pin pair can support differential input and output buffers.

The supported I/O standards such as Differential SSTL-12, Differential SSTL-15, Differential SSTL-125, and Differential SSTL-135 typically do not require external board termination.

Altera recommends that you use dynamic OCT with these I/O standards to save board space and cost. Dynamic OCT reduces the number of external termination resistors used.

Differential HSTL, SSTL, and HSUL Termination

Differential HSTL, SSTL, and HSUL inputs use LVDS differential input buffers. However, R_D support is only available if the I/O standard is LVDS.

Differential HSTL, SSTL, and HSUL outputs are not true differential outputs. These I/O standards use two single-ended outputs with the second output programmed as inverted.

Figure 5-17: Differential SSTL I/O Standard Termination

This figure shows the details of Differential SSTL I/O termination on Arria V devices.

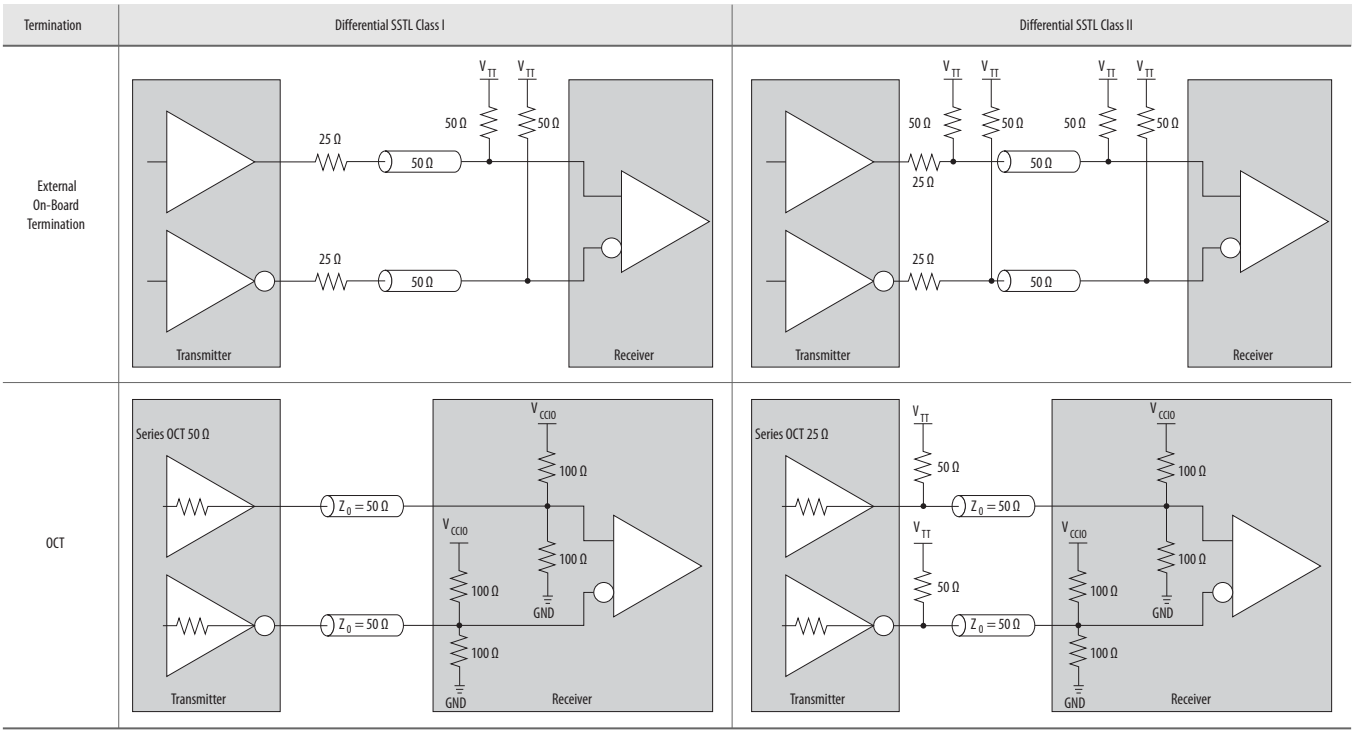


Figure 5-18: Differential HSTL I/O Standard Termination

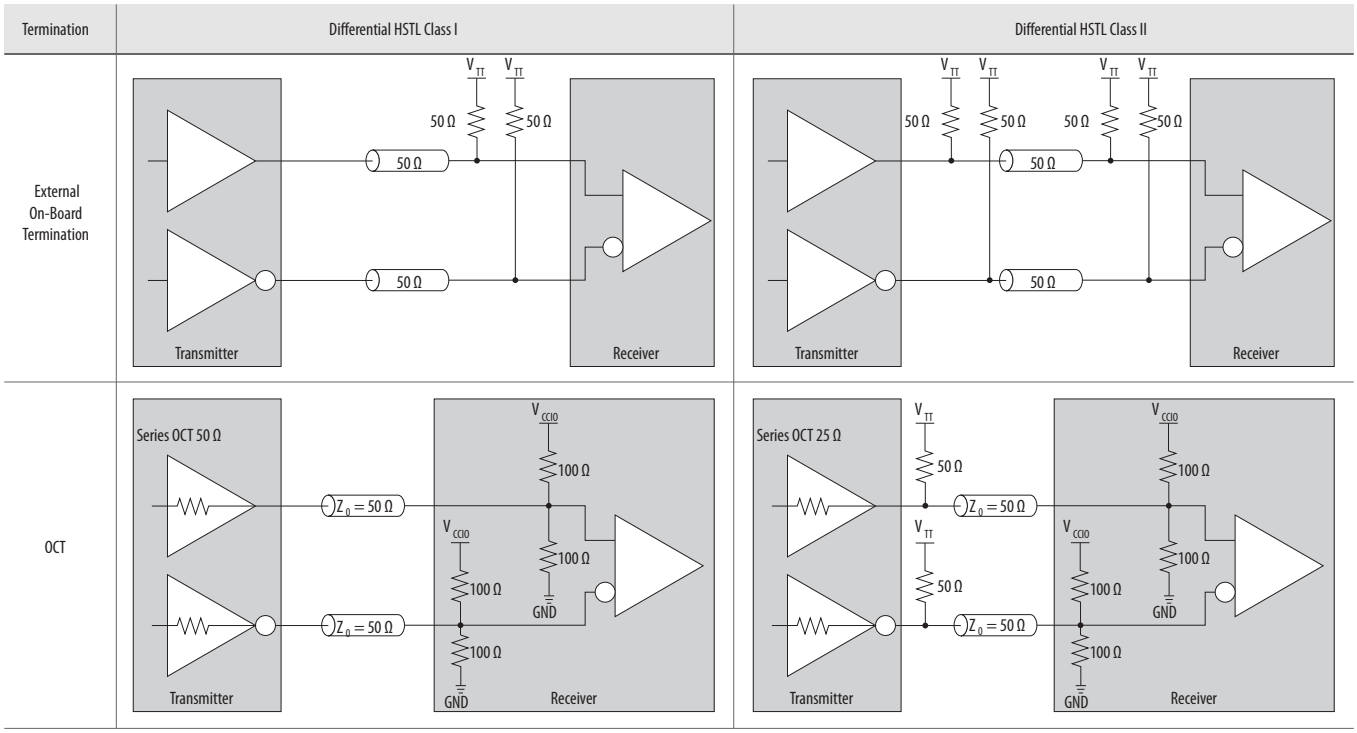
This figure shows the details of Differential HSTL I/O standard termination on Arria V devices.

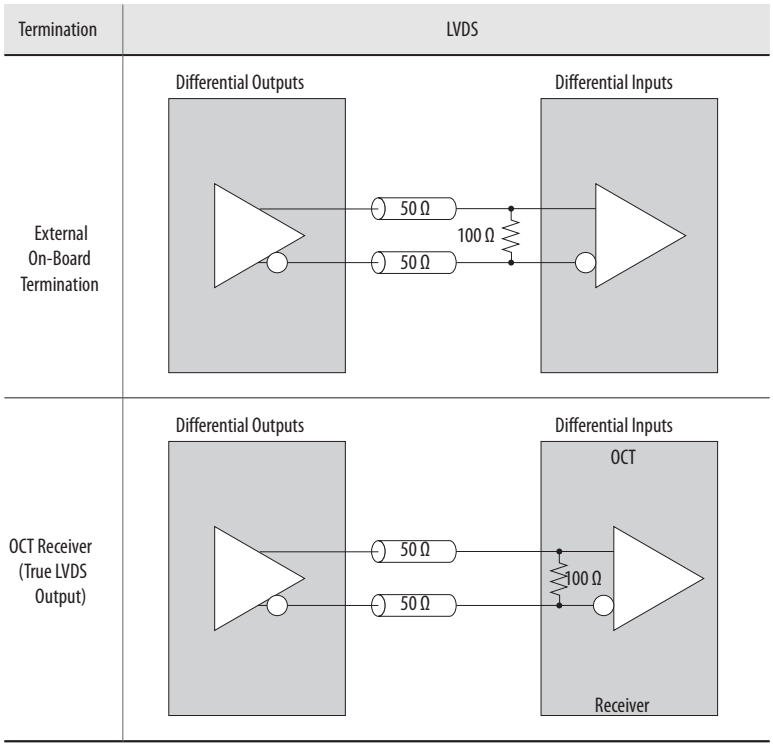


LVDS, RSDS, and Mini-LVDS Termination

All I/O banks have dedicated circuitry to support the true LVDS, RSDS, and mini-LVDS I/O standards by using true LVDS output buffers without resistor networks.

Figure 5-19: LVDS I/O Standard Termination

This figure shows the LVDS I/O standard termination. The on-chip differential resistor is available in all I/O banks.



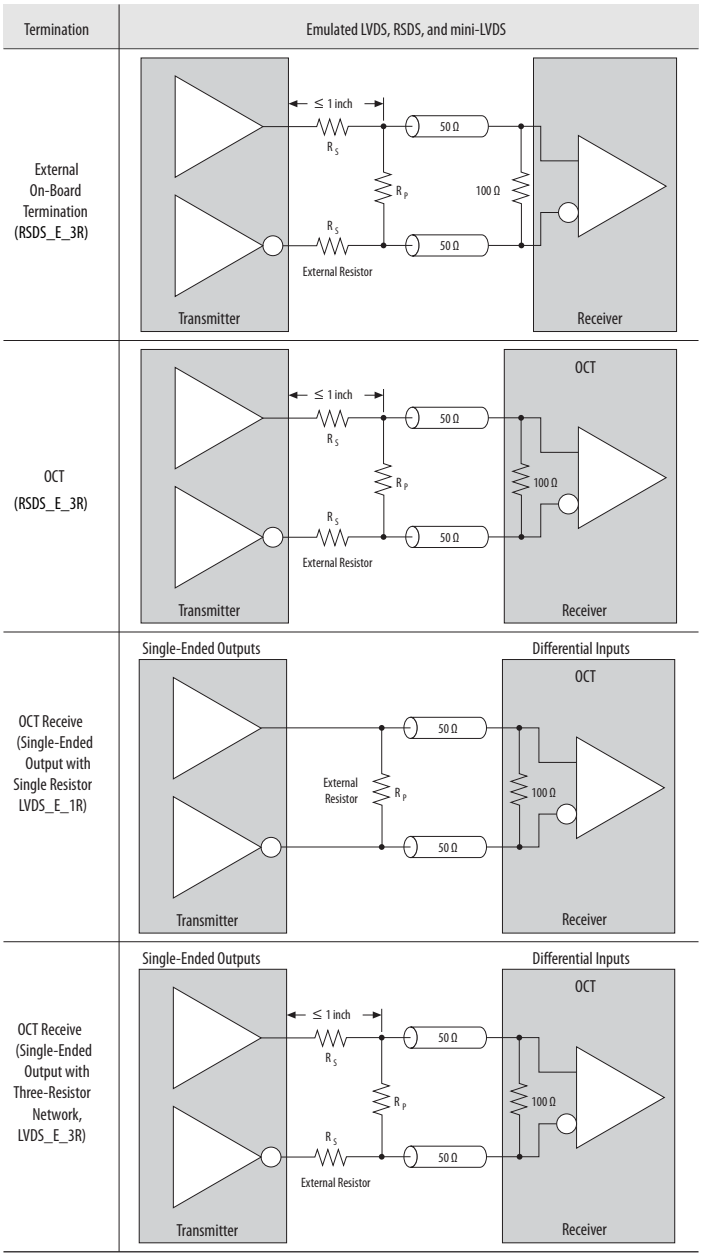
Emulated LVDS, RSDS, and Mini-LVDS Termination

The I/O banks also support emulated LVDS, RSDS, and mini-LVDS I/O standards.

Emulated LVDS, RSDS and mini-LVDS output buffers use two single-ended output buffers with an external single-resistor or three-resistor network, and can be tri-stated.

Figure 5-20: Emulated LVDS, RSDS, or Mini-LVDS I/O Standard Termination

The output buffers, as shown in this figure, are available in all I/O banks. R_S and R_P values are pending characterization.



To meet the RSDS or mini-LVDS specifications, you require a resistor network to attenuate the output-voltage swing.

You can modify the three-resistor network values to reduce power or improve the noise margin. Choose resistor values that satisfy the following equation.

Figure 5-21: Resistor Network Calculation

$$\frac{R_S \times \frac{R_P}{2}}{R_S + \frac{R_P}{2}} = 50\ \Omega$$

Note: Altera recommends that you perform additional simulations with IBIS or SPICE models to validate that the custom resistor values meet the RSDS or mini-LVDS I/O standard requirements.

For information about the data rates supported for external single resistor or three-resistor network, refer to the device datasheet.

Related Information

- **Arria V Device Datasheet**
- **National Semiconductor (www.national.com)**
  For more information about the RSDS I/O standard, refer to the *RSDS Specification* on the National Semiconductor web site.

LVPECL Termination

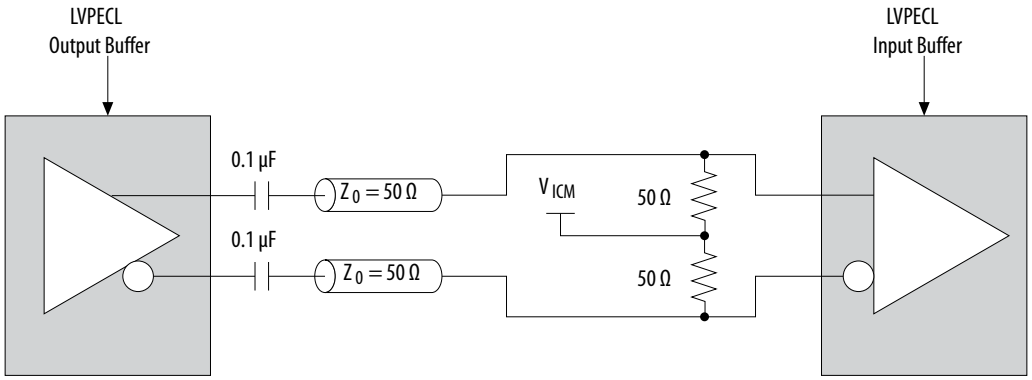
The Arria V devices support the LVPECL I/O standard on input clock pins only:

- LVPECL input operation is supported using LVDS input buffers.
- LVPECL output operation is not supported.

Use AC coupling if the LVPECL common-mode voltage of the output buffer does not match the LVPECL input common-mode voltage.

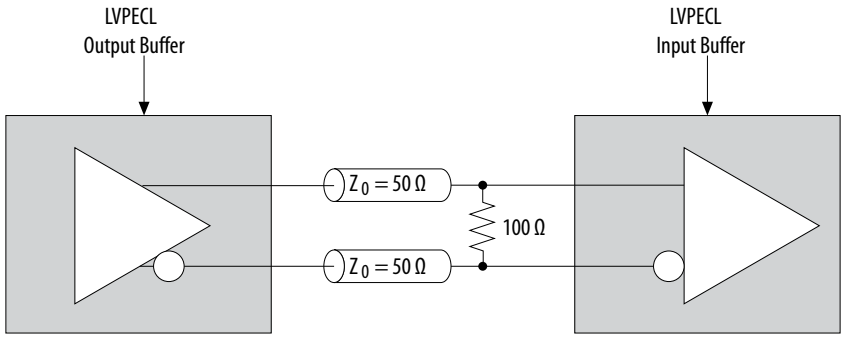
Note: Altera recommends that you use IBIS models to verify your LVPECL AC/DC-coupled termination.

Figure 5-22: LVPECL AC-Coupled Termination



Support for DC-coupled LVPECL is available if the LVPECL output common mode voltage is within the Arria V LVPECL input buffer specification.

Figure 5-23: LVPECL DC-Coupled Termination



For information about the V_{ICM} specification, refer to the device datasheet.

Document Revision History

Date	Version	Changes
January 2015	2015.01.23	• Corrected truncated sentence in the note about the recommendation to use dynamic OCT for several I/O standards with DDR3 external memory interface. • Added pin placement guidelines for general purpose high-speed signals faster than 200 MHz. • Added 3.3V to Arria V I/O Standards Voltage Levels table for 3.3V LVTTL/3.3V LVCMOS, 3.0V LVTTL/3.0V LVCMOS and 2.5V LVCMOS I/O Standard. • Clarified that dedicated configuration pins, clock pins and JTAG pins do not support programmable pull-up resistor but these pins have fixed value of internal pull-up resistors. • Moved the Open-Drain Output, Bus-Hold Circuitry and Pull-up Resistor sections to Programmable IOE Features in Arria V Devices. • Update Open-Drain Output section with steps to enable open-drain output in Assignment Editor.

Date	Version	Changes
June 2014	2014.06.30	• Added footnote to clarify that some of the voltage levels listed in the MultiVolt I/O support table are for showing that multiple single-ended I/O standards are not compatible with certain V_{CCIO} voltages. • Updated the I/O banks locations figures to match the available modular I/O banks for Arria V GX, GT, SX, and ST devices. • Added information to clarify that programmable output slew-rate is available for single-ended and emulated LVDS I/O standards. • Finalized calibrated R_S and R_T OCT values and updated the R_T OCT values for HSUL-12 and Differential HSUL-12 I/O standards. • Updated the V_{CCPD} guideline to clarify that bank 7A is not available as user I/O bank. In Arria V SX and ST devices, banks 6A, 6B, and 7A through 7E are allocated for the HPS.
January 2014	2014.01.10	• Updated statements in several topics to clarify that each modular I/O bank can support multiple I/O standards that use the same voltages. • Updated the guideline topic about using the same V_{CCPD} for I/O banks in the same V_{CCPD} group to improve clarity. • Added the optional PCI clamp diode to the figure showing the IOE structure. • Changed all "SoC FPGA" to "SoC". • Removed SSTL-125 from the list of supported I/O standards for the HPS I/O. • Removed all "preliminary" marks. • Removed the statement specifying that value "0" of the programmable V_{OD} is only available for RSDS and mini-LVDS I/O standards only. The value is now available for the LVDS I/O standards. • Clarified that you can only use R_D OCT if V_{CCPD} is 2.5 V. • Added link to Knowledge Base article that clarifies about vertical migration (drop-in compatibility). • Corrected the modular I/O banks tables for Arria V SX and ST devices. Bank 7G, available in the F1517 package, is an FPGA I/O bank instead of an HPS column I/O bank. The number of I/O pins remain the same.
August 2013	2013.08.19	Added 3.3 V input signal for 2.5 V V_{CCIO} in the table listing the MultiVolt I/O support.
June 2013	2013.06.21	• Removed 3.3 V input signal for 2.5 V V_{CCIO} in the table listing the MultiVolt I/O support. • Updated the topic about LVDS input R_D OCT to remove the requirement for setting the V_{CCIO} to 2.5 V. R_D OCT now requires only that the V_{CCPD} is 2.5 V. • Updated the topic about LVPECL termination to improve clarity.

Date	Version	Changes
May 2013	2013.05.06	• Moved all links to the Related Information section of respective topics for easy reference. • Added link to the known document issues in the Knowledge Base. • Added note about the power-up sequence requirement if you plan to migrate your design to devices that require the specific power-up sequence. • Updated the R_T OCT input termination settings for the 1.5 V SSTL I/O standards. • Updated the maximum speed of RSDS and mini-LVDS to 360 Mbps and 400 Mbps, respectively, in the notes for the supported FPGA I/O standards table.
December 2012	2012.12.04	• Added LVVTL and LVCMOS voltage levels for the Arria V GZ variant, and corrected the LVVTL and LVCMOS voltage levels for the Arria V GX, GT, SX, and ST devices. • Updated the SSTL and HSTL I/O termination figures to add VREF inputs for OCT in bidirectional pins.

Date	Version	Changes
November 2012	2012.11.19	• Reorganized content and updated template. • Added the I/O resources per package and I/O vertical migration sections for easy reference. • Added the steps to verify pin migration compatibility using the Quartus II software. • Updated the I/O standards support table with Arria V GZ and HPS I/O information. • Updated the guideline about mixing voltage-referenced and non-voltage-referenced I/O standards to include Arria V GZ information. • Updated the guideline about observing device absolute maximum rating for 3.3 V interfacing, specifically the off-chip clamping diode usage for Arria V GZ. • Updated the VREF pin restrictions guideline to specify that it applies only to Arria V GX, GT, SX, and ST, but not Arria V GZ. • Added the I/O bank locations for Arria V GZ devices. • Rearranged the I/O banks groups tables for easier reference. • Added modular I/O banks for Arria V GZ devices. • Restructured the information in the topic about I/O buffers and registers to improve clarity and for faster reference. • Added Arria V GZ and HPS information to the topic on programmable IOE features. • Rearranged the tables about on-chip I/O termination for clarity and topic-based reference. • Added Arria V GZ OCT information to all on-chip I/O termination tables. • Added all I/O standards and external termination schemes supported by all Arria V devices to the external I/O termination table.
June 2012	2.0	Updated for the Quartus II software v12.0 release: • Restructured chapter. • Added "Design Considerations", "VCCIO Restriction", "LVDS Channels", "Modular I/O Banks", and "OCT Calibration Block" sections. • Added Figure 5–1, Figure 5–2, and Figure 5–3 • Updated Table 5–1, Table 5–6, and Table 5–8. • Updated Figure 5–19 with emulated LVDS with external single resistor.
February 2012	1.2	Updated Table 5–3.
November 2011	1.1	• Restructured chapter. • Updated Table 5–3.
May 2011	1.0	Initial release.

High-Speed Differential I/O Interfaces and DPA in Arria V Devices

6

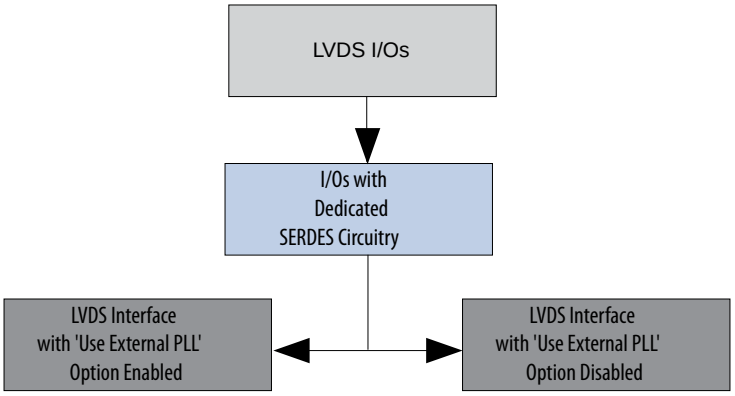
2015.01.23

AV-52006 Subscribe Send Feedback

The high-speed differential I/O interfaces and dynamic phase alignment (DPA) features in Arria V devices provide advantages over single-ended I/Os and contribute to the achievable overall system bandwidth. Arria V devices support low-voltage differential signaling (LVDS), mini-LVDS, and reduced swing differential signaling (RSDS) differential I/O standards.

The following figure shows the I/O bank support for high-speed differential I/O in the Arria V devices.

Figure 6-1: I/O Bank Support for High-Speed Differential I/O



Related Information

  Lists the planned updates to the *Arria V Device Handbook* chapters.

Dedicated High-Speed Circuitries in Arria V Devices

The following dedicated circuitries are available in the Arria V device family to support high-speed differential I/O:

- Differential I/O buffer
- Transmitter serializer
- Receiver deserializer
- Data realignment (Bit-slip)
- DPA
- Synchronizer (FIFO buffer)
- Phase-locked loops (PLLs)

SERDES and DPA Bank Locations in Arria V Devices

The dedicated serializer/deserializer (SERDES) and DPA circuitry that supports high-speed differential I/Os is located in the top and bottom banks of the Arria V devices.

The following figures show the high-level location of SERDES/DPA in the Arria V devices.

Figure 6-2: High-Speed Differential I/Os with DPA Locations in Arria V GX A1 and A3 Devices, and Arria V GT C3 Device.

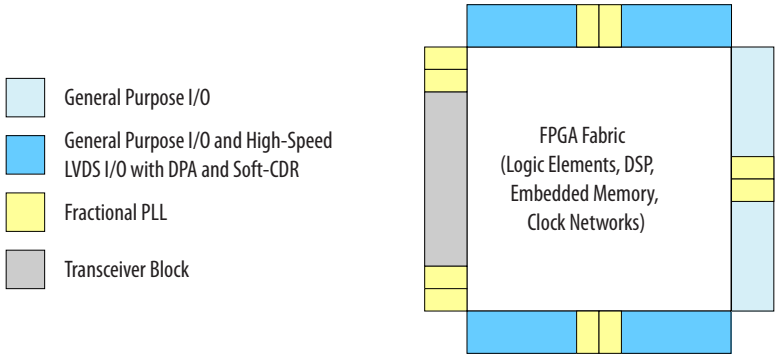

Figure 6-3: High-Speed Differential I/Os with DPA Locations in Arria V GX A5, A7, B1, and B3 Devices, and Arria V GT C7, D3, and D7 Devices

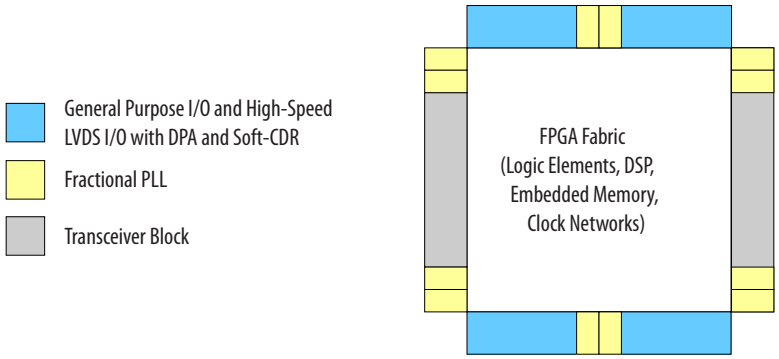

Figure 6-4: High-Speed Differential I/Os with DPA Locations in Arria V GX B5 and B7 Devices

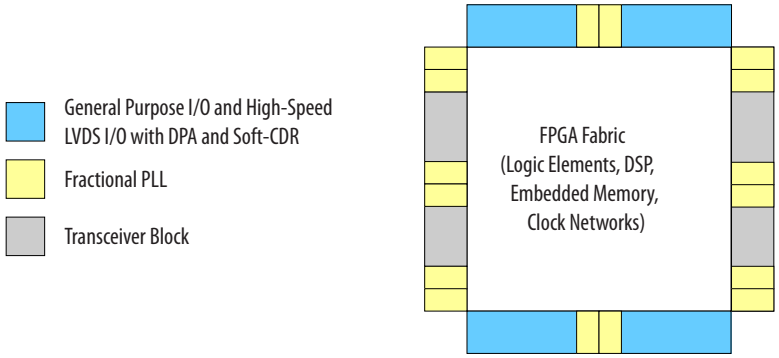

Figure 6-5: High-Speed Differential I/Os with DPA Locations in Arria V GZ Devices

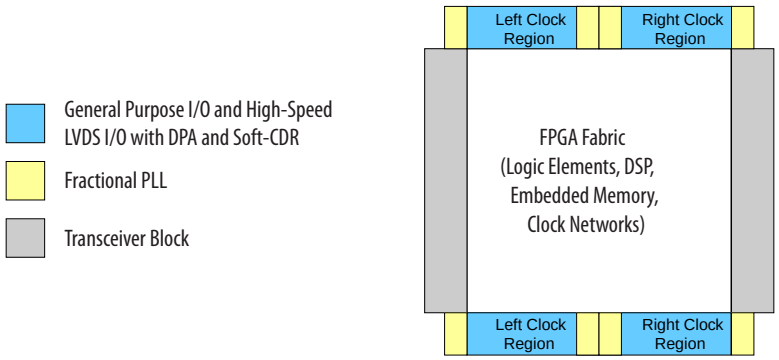


Related Information

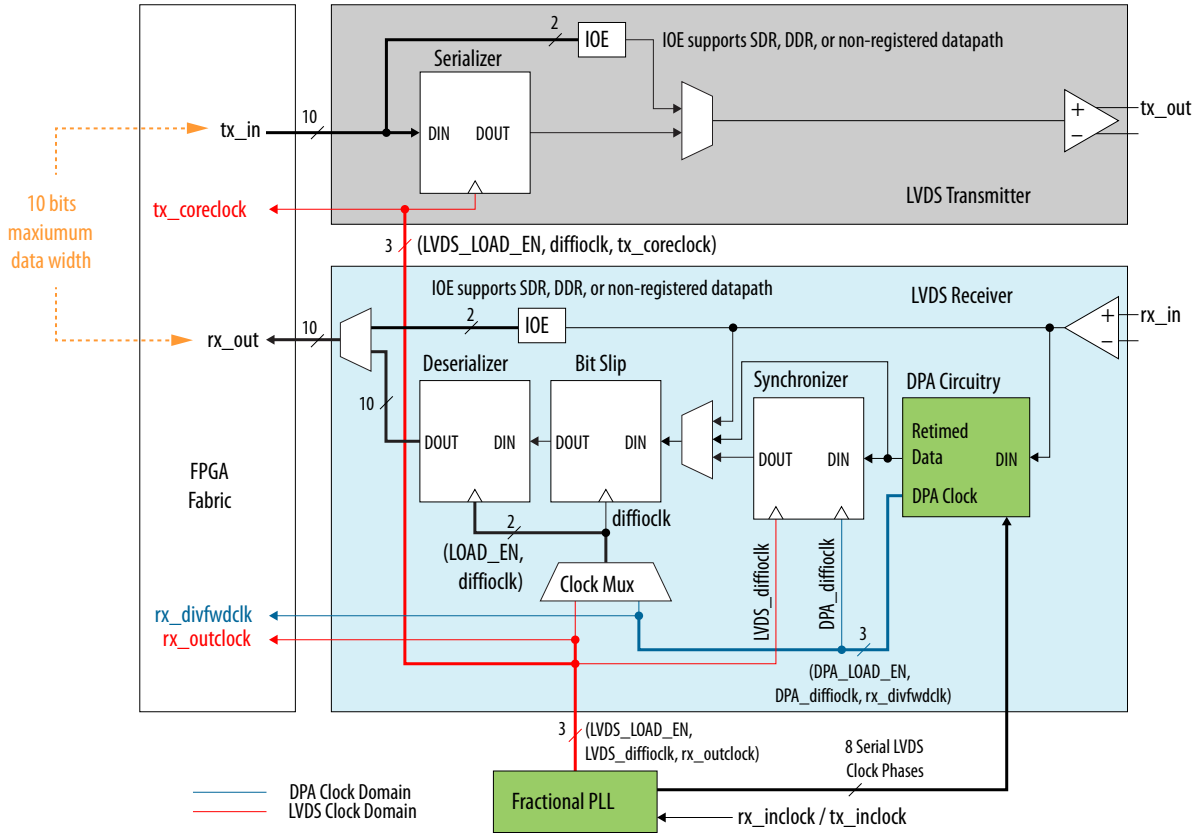
PLLs and Clocking for Arria V Devices on page 6-7

LVDS SERDES Circuitry

The Arria V devices have built-in serializer/deserializer (SERDES) circuitry that supports high-speed LVDS interfaces. You can configure the SERDES circuitry to support source-synchronous communication protocols such as RapidIO®, XSBI, serial peripheral interface (SPI), and asynchronous protocols such as Gigabit Ethernet (GbE).

The following figure shows a transmitter and receiver block diagram for the LVDS SERDES circuitry with the interface signals of the transmitter and receiver data paths.

Figure 6-6: LVDS SERDES



The preceding figure shows a shared PLL between the transmitter and receiver. If the transmitter and receiver do not share the same PLL, you require two fractional PLLs. In single data rate (SDR) and double data rate (DDR) modes, the data width is 1 and 2 bits, respectively.

The ALTLVDS transmitter and receiver requires various clock and load enable signals from a fractional PLL. The Quartus II software configures the PLL settings automatically. The software is also responsible for generating the various clock and load enable signals based on the input reference clock and selected data rate.

Note: For the maximum data rate supported by the Arria V devices, refer to the device overview.

True LVDS Buffers in Arria V Devices

The following tables list the number of true LVDS buffers supported in Arria V devices with these conditions:

- The LVDS channel count does not include dedicated clock pins.
- Dedicated SERDES and DPA is available for top and bottom banks only.
- Each I/O sub-bank can support up to two independent ALTLVDS interfaces. For example, you can place two ALTLVDS interfaces in bank 8A driven by two different PLLs, provided that the LVDS channels are not interleaved.

Emulated LVDS Buffers in Arria V Devices

The Arria V device family supports emulated LVDS:

- You can use unutilized true LVDS input channels as emulated LVDS output buffers (eTX).
- The emulated differential output buffers support tri-state capability.

High-Speed I/O Design Guidelines for Arria V Devices

There are several considerations that require your attention to ensure the success of your designs. Unless noted otherwise, these design guidelines apply to all variants of this device family.

PLLs and Clocking for Arria V Devices

To generate the parallel clocks (`rx_outclock` and `tx_outclock`) and high-speed clocks (`diffioclk`), the Arria V devices provide fractional PLLs in the high-speed differential I/O receiver and transmitter channels.

Related Information

- **Guideline: Use PLLs in Integer PLL Mode for LVDS** on page 6-7
- **SERDES and DPA Bank Locations in Arria V Devices** on page 6-2
  Provides information about the PLL locations available for each Arria V device.
- **Guideline: Use High-Speed Clock from PLL to Clock LVDS SERDES Only** on page 6-8

Guideline: Use PLLs in Integer PLL Mode for LVDS

To drive the LVDS channels, you must use the PLLs in integer PLL mode. The center or corner PLLs can drive the LVDS receiver and transmitter channels.

However, in Arria V GZ devices, the clock tree network cannot cross over to different I/O regions. For example, the top left corner PLL cannot cross over to drive the LVDS receiver and transmitter channels on the top right I/O bank.

Related Information

Pin Placement Guidelines for DPA and Non-DPA Differential Channels on page 6-13
Provides more information about the fractional PLL clocking restrictions.

Guideline: Use High-Speed Clock from PLL to Clock LVDS SERDES Only

The high-speed clock generated from the PLL is intended to clock the LVDS SERDES circuitry only. Do not use the high-speed clock to drive other logic because the allowed frequency to drive the core logic is restricted by the PLL F_{OUT} specification.

For more information about the F_{OUT} specification, refer to the device datasheet.

LVDS Interface with External PLL Mode

The MegaWizard Plug-In Manager provides an option for implementing the LVDS interface with the **Use External PLL** option. With this option enabled you can control the PLL settings, such as dynamically reconfiguring the PLL to support different data rates, dynamic phase shift, and other settings. You must also instantiate the an Altera_PLL megafunction to generate the various clock and load enable signals.

If you enable the **Use External PLL** option with the ALTLVDS transmitter and receiver, the following signals are required from the Altera_PLL megafunction:

- Serial clock input to the SERDES of the ALTLVDS transmitter and receiver
- Load enable to the SERDES of the ALTLVDS transmitter and receiver
- Parallel clock used to clock the transmitter FPGA fabric logic and parallel clock used for the receiver
- Asynchronous PLL reset port of the ALTLVDS receiver

Altera_PLL Signal Interface with ALTLVDS Megafunction

Table 6-6: Signal Interface Between Altera_PLL and ALTLVDS Megafunctions

This table lists the signal interface between the output ports of the Altera_PLL megafunction and the input ports of the ALTLVDS transmitter and receiver. As an example, the table lists the serial clock output, load enable output, and parallel clock output generated on ports outclk0, outclk1, and outclk2, along with the locked signal of the Altera_PLL instance. You can choose any of the PLL output clock ports to generate the interface clocks.

From the Altera_PLL Megafunction	To the ALTLVDS Transmitter	To the ALTLVDS Receiver
Serial clock output (outclk0) The serial clock output (outclk0) can only drive `tx_inclock` on the ALTLVDS transmitter, and `rx_inclock` and `rx_dpaclock` on the ALTLVDS receiver. This clock cannot drive the core logic.	`tx_inclock` (serial clock input to the transmitter)	`rx_inclock` (serial clock input) `rx_dpaclock`
Load enable output (outclk1)	`tx_enable` (load enable to the transmitter)	`rx_enable` (load enable for the deserializer)
Parallel clock output (outclk2)	Parallel clock used inside the transmitter core logic in the FPGA fabric	`rx_syncclock` (parallel clock input) and parallel clock used inside the receiver core logic in the FPGA fabric

From the Altera_PLL Megafunction	To the ALTLVDS Transmitter	To the ALTLVDS Receiver
~(locked)	—	`pll_areset` (asynchronous PLL reset port) The `pll_areset` signal is automatically enabled for the LVDS receiver in external PLL mode. This signal does not exist for LVDS transmitter instantiation when the external PLL option is enabled.

Note: With soft SERDES, a different clocking requirement is needed.

Related Information

LVDS SERDES Transmitter/Receiver (ALTLVDS_RX/TX) Megafunction User Guide
More information about the different clocking requirement for soft SERDES.

Altera_PLL Parameter Values for External PLL Mode

The following examples show the clocking requirements to generate output clocks for ALTLVDS_TX and ALTLVDS_RX using the Altera_PLL megafunction. The examples set the phase shift with the assumption that the clock and data are edge aligned at the pins of the device.

Note: For other clock and data phase relationships, Altera recommends that you first instantiate your ALTLVDS_RX and ALTLVDS_TX interface without using the external PLL mode option. Compile the megafunctions in the Quartus II software and take note of the frequency, phase shift, and duty cycle settings for each clock output. Enter these settings in the Altera_PLL megafunction parameter editor and then connect the appropriate output to the ALTLVDS_RX and ALTLVDS_TX megafunctions.

Table 6-7: Example: Generating Output Clocks Using an Altera_PLL Megafunction (No DPA and Soft-CDR Mode)

This table lists the parameter values that you can set in the Altera_PLL parameter editor to generate three output clocks using an Altera_PLL megafunction if you are not using DPA and soft-CDR mode.

Parameter	outclk0 (Connects to the `tx_inclock` port of ALTLVDS_TX and the `rx_inclock` port of ALTLVDS_RX)	outclk1 (Connects to the `tx_enable` port of ALTLVDS_TX and the `rx_enable` port of ALTLVDS_RX)	outclk2 (Used as the core clock for the parallel data registers for both transmitter and receiver, and connects to the `rx_syncclock` port of ALTLVDS_RX)
Frequency	data rate	data rate/serialization factor	data rate/serialization factor
Phase shift	–180°	[(deserialization factor – 2)/ deserialization factor] x 360°	–180/serialization factor (outclk0 phase shift divided by the serialization factor)

Parameter	outclk0 (Connects to the tx_inclock port of ALTLVDS_TX and the rx_inclock port of ALTLVDS_RX)	outclk1 (Connects to the tx_enable port of ALTLVDS_TX and the rx_enable port of ALTLVDS_RX)	outclk2 (Used as the core clock for the parallel data registers for both transmitter and receiver, and connects to the rx_syncclock port of ALTLVDS_RX)
Duty cycle	50%	100/serialization factor	50%

Figure 6-7: Phase Relationship for External PLL Interface Signals

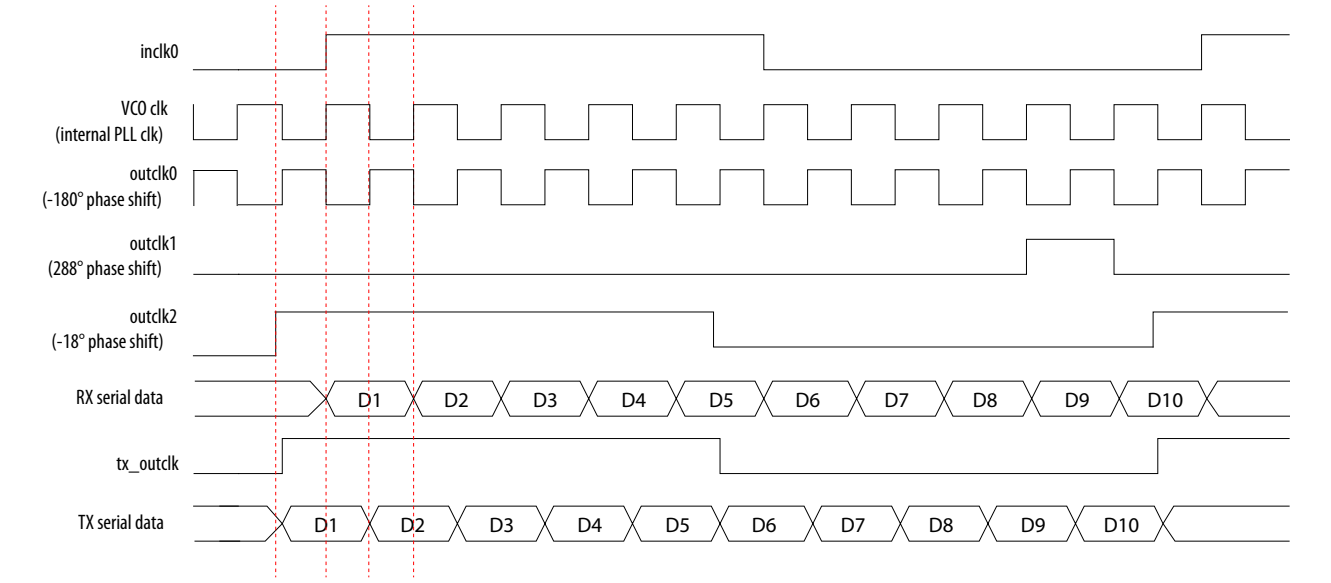

Table 6-8: Example: Generating Output Clocks Using an Altera_PLL Megafunction (With DPA and Soft-CDR Mode)

This table lists the parameter values that you can set in the Altera_PLL parameter editor to generate four output clocks using an Altera_PLL megafunction if you are using DPA and soft-CDR mode. The `locked` output port of Altera_PLL must be inverted and connected to the `pll_areset` port of the ALTLVDS_RX megafunction if you are using DPA and soft-CDR mode.

Parameter	outclk0 (Connects to the tx_inclock port of ALTLVDS_TX and the rx_inclock port of ALTLVDS_RX)	outclk1 (Connects to the tx_enable port of ALTLVDS_TX and the rx_enable port of ALTLVDS_RX)	outclk2 (Used as the core clock for the parallel data registers for both transmitter and receiver, and connects to the rx_syncclock port of ALTLVDS_RX)	outclk3 (Connects to the rx_dpaclock port of ALTLVDS_RX)
Frequency	data rate	data rate/serialization factor	data rate/serialization factor	data rate

Parameter	outclk0 (Connects to the tx_inclock port of ALTLVDS_TX and the rx_inclock port of ALTLVDS_RX)	outclk1 (Connects to the tx_enable port of ALTLVDS_TX and the rx_enable port of ALTLVDS_RX)	outclk2 (Used as the core clock for the parallel data registers for both transmitter and receiver, and connects to the rx_syncclock port of ALTLVDS_RX)	outclk3 (Connects to the rx_dpaclock port of ALTLVDS_RX)
Phase shift	–180°	[(deserialization factor - 2)/deserialization factor] x 360°	–180/serialization factor (outclk0 phase shift divided by the serialization factor)	–180°
Duty cycle	50%	100/serialization factor	50%	50%

Connection between Altera_PLL and ALTLVDS

Figure 6-8: LVDS Interface with the Altera_PLL Megafunction (Without DPA and Soft-CDR Mode)

This figure shows the connections between the Altera_PLL and ALTLVDS megafunction if you are not using DPA and soft-CDR mode.

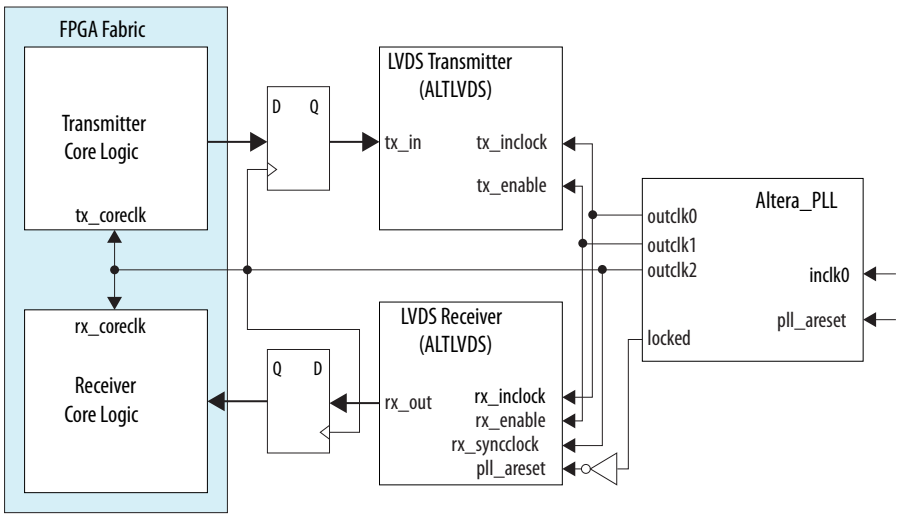

Figure 6-9: LVDS Interface with the Altera_PLL Megafunction (With DPA)

This figure shows the connections between the Altera_PLL and ALTLVDS megafunction if you are using DPA. The `locked` output port must be inverted and connected to the `pll_areset` port.

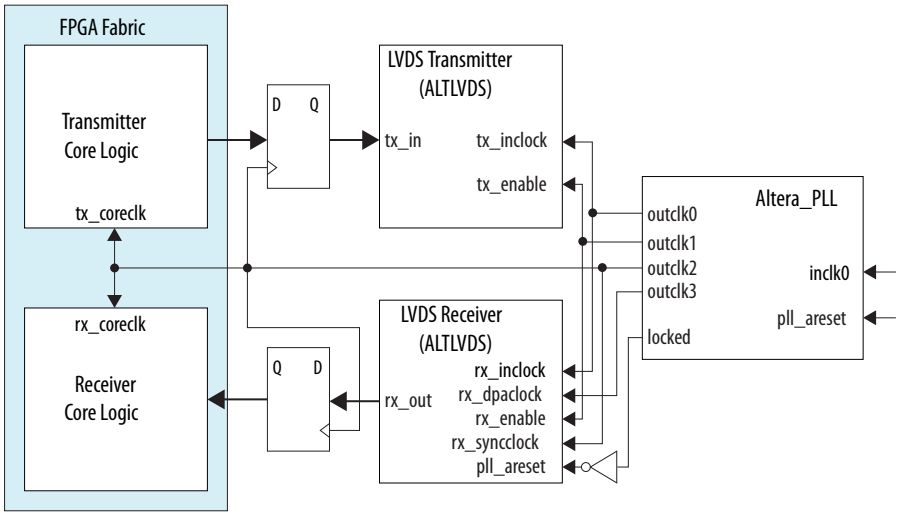

Figure 6-10: LVDS Interface with the Altera_PLL Megafunction (With Soft-CDR Mode)

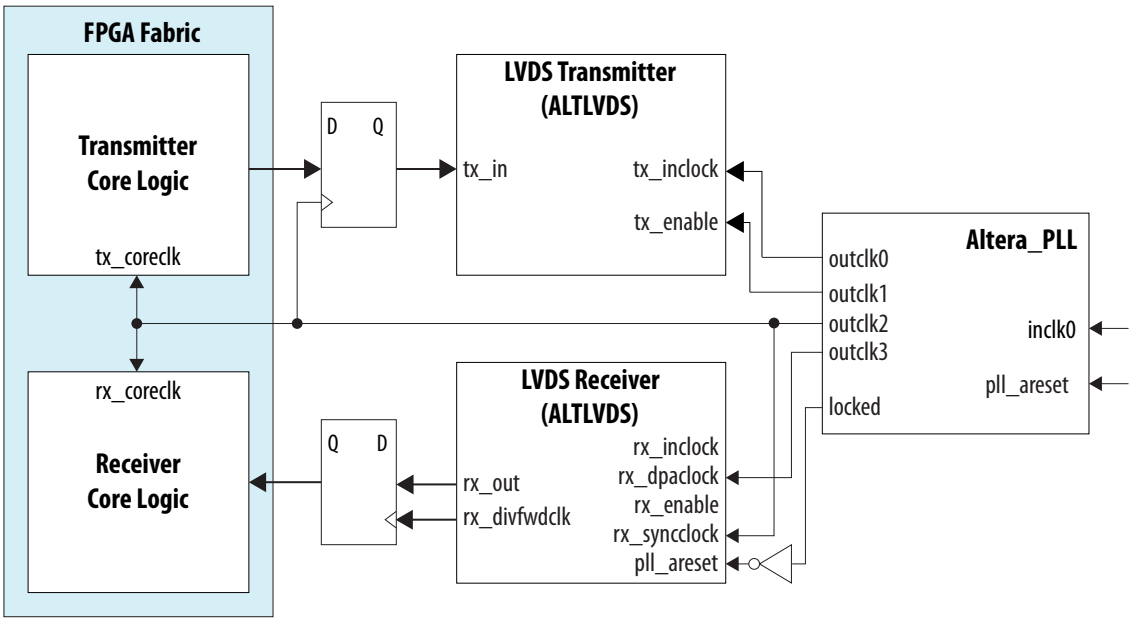
This figure shows the connections between the Altera_PLL and ALTLVDS megafunction if you are using soft-CDR mode. The `locked` output port must be inverted and connected to the `pll_areset` port.



When generating the Altera_PLL megafunction, the **Left/Right PLL** option is configured to set up the PLL in LVDS mode. Instantiation of `pll_areset` is optional.

The `rx_enable` and `rx_inclock` input ports are not used and can be left unconnected.

Pin Placement Guidelines for DPA and Non-DPA Differential Channels

DPA usage adds some constraints on the placement of high-speed differential channels. If DPA-enabled or DPA-disabled differential channels[17] in the differential banks are used, you must adhere to the differential pin placement guidelines to ensure the proper high-speed operation. The Quartus II compiler automatically checks the design and issues an error message if the guidelines are not followed.

Note: The figures in this section show guidelines for using corner and center PLLs but do not necessarily represent the exact locations of the high-speed LVDS I/O banks.

Related Information

Guideline: Use PLLs in Integer PLL Mode for LVDS on page 6-7

Guideline: Using DPA-Enabled Differential Channels

Each differential receiver in an I/O block has a dedicated DPA circuit to align the phase of the clock to the data phase of its associated channel. If you enable a DPA channel in a bank, you can use both single-ended I/Os and differential I/O standards in the bank.

You can place double data rate I/O (DDIO) output pins within I/O modules that have the same pad group number as a SERDES differential channel. However, you cannot place SDR I/O output pins within I/O modules that have the same pad group number as a receiver SERDES differential channel. You must implement the input register within the FPGA fabric logic.

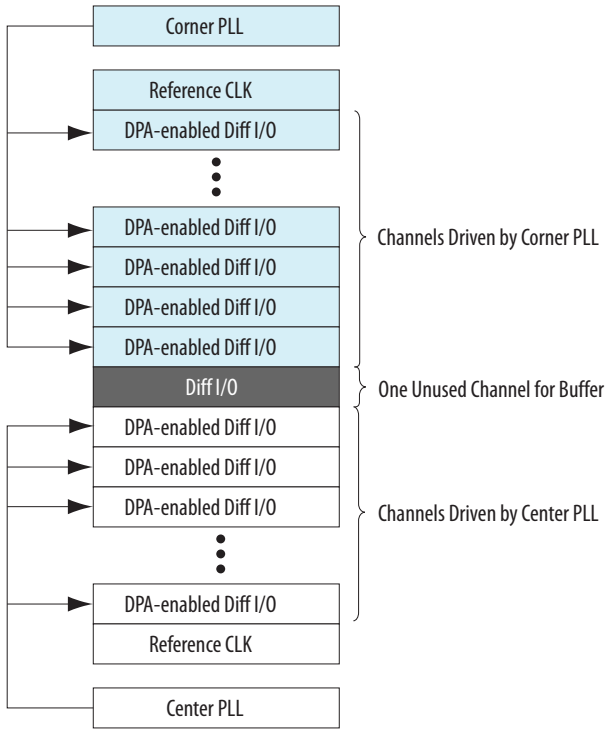
If you use DPA-enabled channels in differential banks, adhere to the following guidelines.

Using Center and Corner PLLs

If two PLLs drive the DPA-enabled channels in a bank—the corner and center PLL drive one group each—there must be at least one row (one differential channel) of separation between the two groups of DPA-enabled channels, as shown in the following figure.

[17] DPA-enabled differential channels refer to DPA mode or soft-CDR mode while DPA disabled channels refer to non-DPA mode.

Figure 6-11: Center and Corner PLLs Driving DPA-enabled Differential I/Os in the Same Bank



This separation prevents noise mixing because the two groups can operate at independent frequencies. No separation is necessary if a single PLL is driving both the DPA-enabled channels and DPA-disabled channels.

Using Both Center PLLs

You can use center PLLs to drive DPA-enabled channels simultaneously, if they drive these channels in their adjacent banks only, as shown in the previous figure. If one of the center PLLs drives the DPA-enabled channels in the left and right I/O banks in Arria V GX, GT, SX, or ST devices, you cannot use the other center PLL for DPA-enabled channels. If the center left PLL drives the DPA-enabled channels in the right I/O bank, the right center PLL cannot drive the DPA-enabled channels in the left I/O bank, and vice versa. The center PLLs cannot drive cross-banks simultaneously in Arria V GZ devices. Refer to the following figures.

Figure 6-12: Center PLLs Driving DPA-enabled Differential I/Os in Arria V GX, GT, SX, and ST Devices

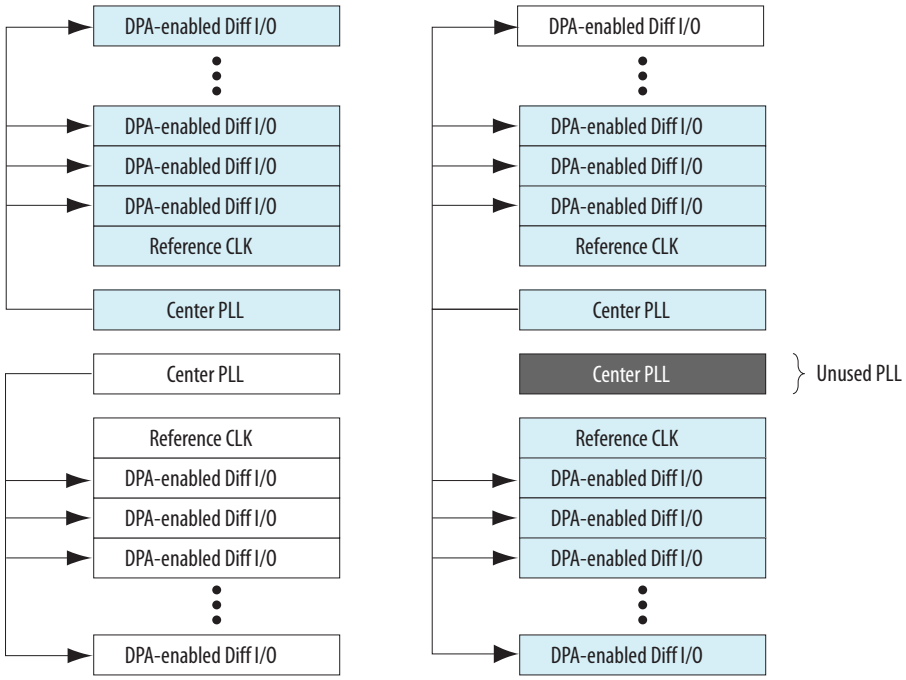


Figure 6-13: Center PLLs Driving DPA-enabled Differential I/Os in Arria V GZ Devices

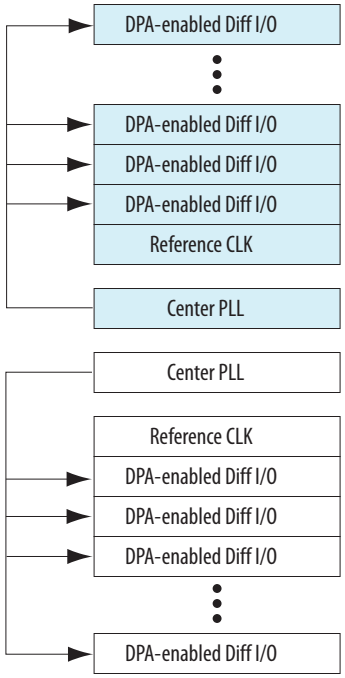

Figure 6-14: Invalid Placement of DPA-enabled Differential I/Os Driven by Both Center PLLs

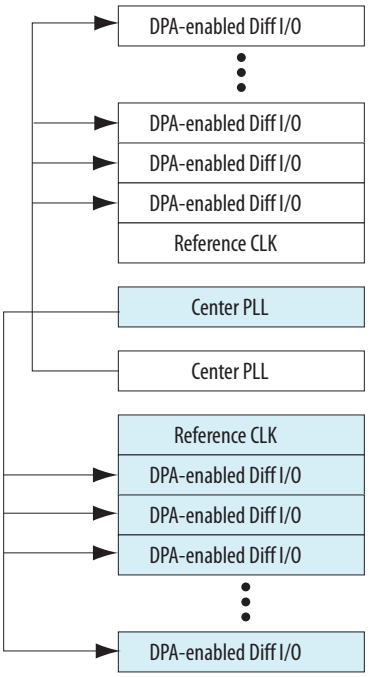


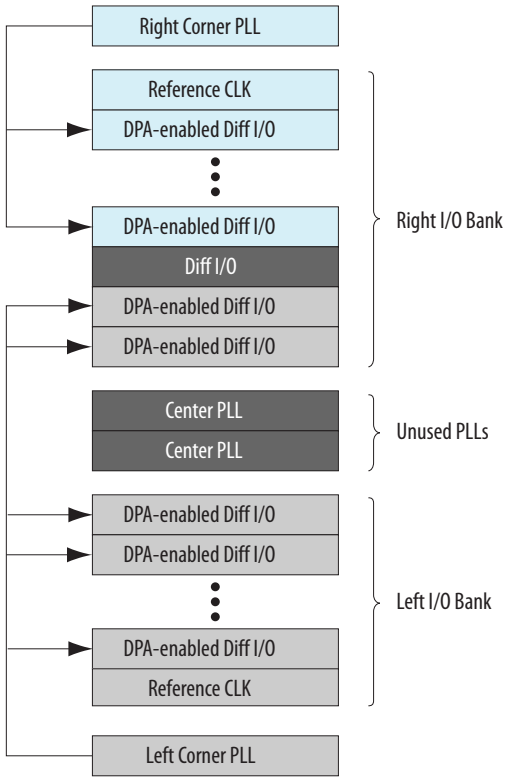
Using Both Corner PLLs

You can use both corner PLLs to drive DPA-enabled channels simultaneously, if they drive the channels in their adjacent banks only. There must be at least one row of separation between the two groups of DPA-enabled channels.

If one of the corner PLLs drives DPA-enabled channels in the left and right I/O banks, you cannot use the center PLLs to drive DPA-enabled channels. You can use the other corner PLL to drive DPA-enabled channels in their adjacent bank only. There must be at least one row of separation between the two groups of DPA-enabled channels.

If the left corner PLL drives DPA-enabled channels in the right I/O bank, the right corner PLL cannot drive DPA-enabled channels in the left I/O bank, and vice versa. In other words, the corner PLLs cannot drive cross-banks simultaneously, as shown in the following figure.

Figure 6-15: Corner PLLs Driving DPA-enabled Differential I/Os



DPA Restrictions

Because there is only a single DPA clock bus, a PLL drives a continuous series of DPA channels.

To prevent noise mixing, use one row of separation between two groups of DPA channels.

Guideline: Using DPA-Disabled Differential Channels

If you use DPA-disabled channels, adhere to the following guidelines.

DPA-Disabled Channel Driving Distance

Each PLL can drive all the DPA-disabled channels in the entire bank.

Using Corner and Center PLLs

You can use a corner PLL to drive all transmitter channels and a center PLL to drive all DPA-disabled receiver channels in the same I/O bank. You can drive a transmitter channel and a receiver channel in the same LAB row by two different PLLs. A corner PLL and a center PLL can drive duplex channels in the same I/O bank if the channels that are driven by each PLL are not interleaved. You do not require separation between the group of channels that are driven by the corner and center, left and right PLLs. Refer to the following figures.

Figure 6-16: Corner and Center PLLs Driving DPA-Disabled Differential I/Os in the Same Bank

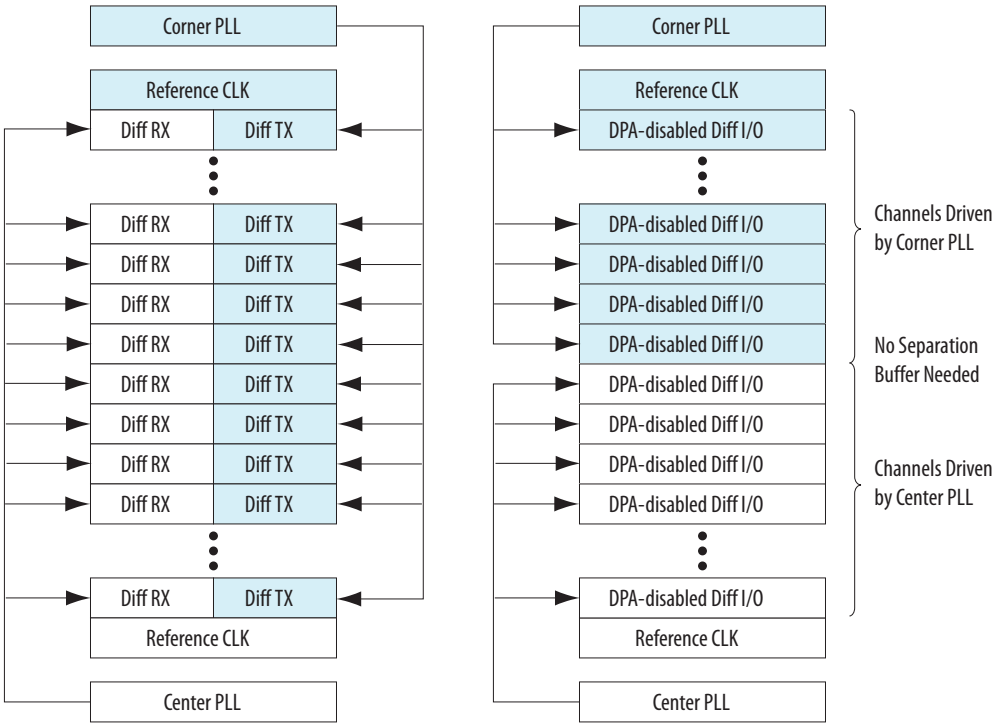


Figure 6-17: Invalid Placement of DPA-disabled Differential I/Os Due to Interleaving of Channels Driven by the Corner and Center PLLs

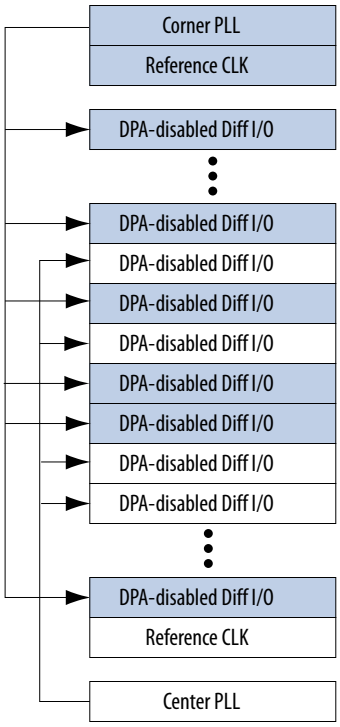
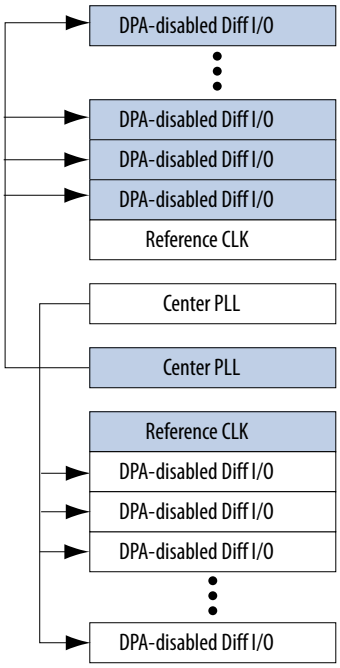


Using Both Center PLLs

You can use both center PLLs simultaneously to drive DPA-disabled channels on left and right I/O banks. Unlike DPA-enabled channels, the center PLLs can drive DPA-disabled channels cross-banks in the Arria V GX, GT, SX, and ST devices. For example, the left center PLL can drive the right I/O bank at the same time the right center PLL is driving the left I/O bank, and vice versa, as shown in the following figure.

Note: In the Arria V GZ devices, the center PLLs cannot drive DPA-disabled channels cross-banks.

Figure 6-18: Both Center PLLs Driving Cross-Bank DPA-Disabled Channels Simultaneously in Arria V GX, GT, SX, and ST Devices



Using Both Corner PLLs

You can use both corner PLLs to drive DPA-disabled channels simultaneously. You can use a corner PLL to drive all the transmitter channels and the other corner PLL to drive all the DPA-disabled receiver channels in the same I/O bank. Both corner PLLs can drive duplex channels in the same I/O bank if the channels that are driven by each PLL are not interleaved. You do not require separation between the groups of channels that are driven by both corner PLLs.

Differential Transmitter in Arria V Devices

The Arria V transmitter contains dedicated circuitry to support high-speed differential signaling. The differential transmitter buffers support the following features:

- LVDS signaling that can drive out LVDS, mini-LVDS, and RSDS signals
- Programmable V_{OD} and programmable pre-emphasis

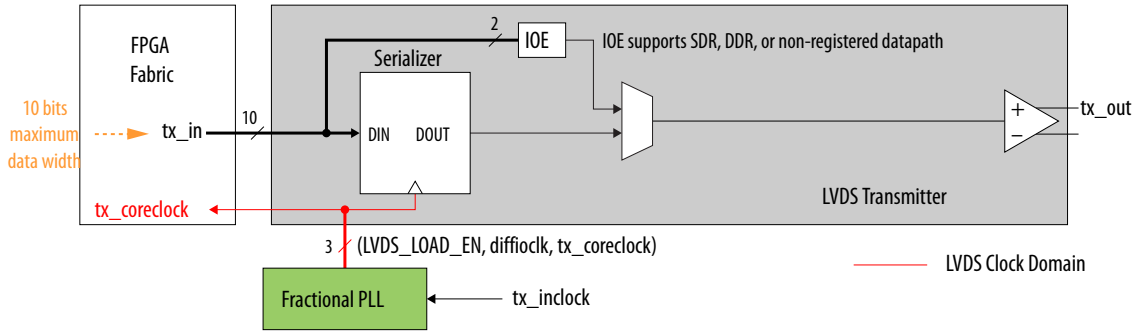
Transmitter Blocks

The dedicated circuitry consists of a true differential buffer, a serializer, and fractional PLLs that you can share between the transmitter and receiver. The serializer takes up to 10 bits wide parallel data from the FPGA fabric, clocks it into the load registers, and serializes it using shift registers that are clocked by the fractional PLL before sending the data to the differential buffer. The MSB of the parallel data is transmitted first.

Note: To drive the LVDS channels, you must use the PLLs in integer PLL mode.

The following figure shows a block diagram of the transmitter. In SDR and DDR modes, the data width is 1 and 2 bits, respectively.

Figure 6-19: LVDS Transmitter



Related Information

Guideline: Use PLLs in Integer PLL Mode for LVDS on page 6-7

Transmitter Clocking

The fractional PLL generates the load enable (`LVDS_LOAD_EN`) signal and the `diffioclk` signal (the clock running at serial data rate) that clocks the load and shift registers. You can statically set the serialization factor to x3, x4, x5, x6, x7, x8, x9, or x10 using the Quartus II software. The load enable signal is derived from the serialization factor setting.

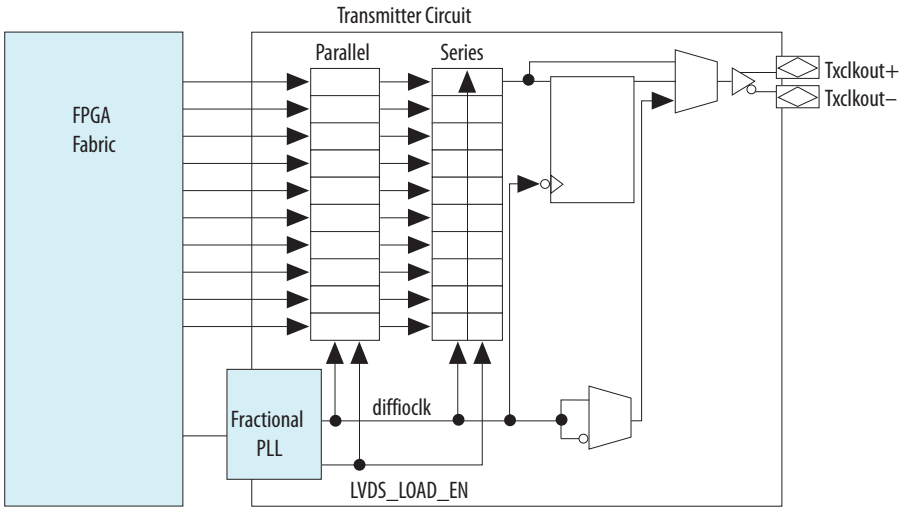
You can configure any Arria V transmitter data channel to generate a source-synchronous transmitter clock output. This flexibility allows the placement of the output clock near the data outputs to simplify board layout and reduce clock-to-data skew.

Different applications often require specific clock-to-data alignments or specific data-rate-to-clock-rate factors. You can specify these settings statically in the Quartus II MegaWizard Plug-In Manager:

- The transmitter can output a clock signal at the same rate as the data—with a maximum output clock frequency that each speed grade of the device supports.
- You can divide the output clock by a factor of 1, 2, 4, 6, 8, or 10, depending on the serialization factor.
- You can set the phase of the clock in relation to the data using internal PLL option of the ALTLVDS megafunction. The fractional PLLs provide additional support for other phase shifts in 45° increments.

The following figure shows the transmitter in clock output mode. In clock output mode, you can use an LVDS channel as a clock output channel.

Figure 6-20: Transmitter in Clock Output Mode



Related Information

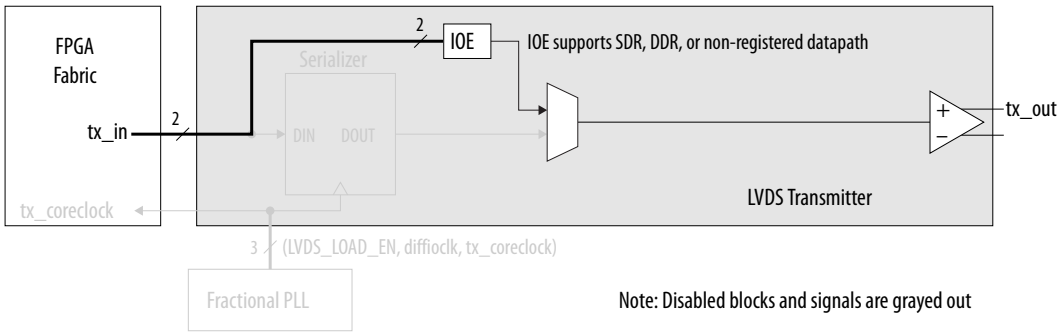
Guideline: Use PLLs in Integer PLL Mode for LVDS on page 6-7

Serializer Bypass for DDR and SDR Operations

You can bypass the serializer to support DDR (x2) and SDR (x1) operations to achieve a serialization factor of 2 and 1, respectively. The I/O element (IOE) contains two data output registers that can each operate in either DDR or SDR mode.

Figure 6-21: Serializer Bypass

This figure shows the serializer bypass path. In DDR mode, `tx_inclock` clocks the IOE register. In SDR mode, data is passed directly through the IOE. In SDR and DDR modes, the data width to the IOE is 1 and 2 bits, respectively.



Programmable Differential Output Voltage

The programmable V_{OD} settings allow you to adjust the output eye opening to optimize the trace length and power consumption. A higher V_{OD} swing improves voltage margins at the receiver end, and a smaller V_{OD} swing reduces power consumption. You can statically adjust the V_{OD} of the differential signal by changing the V_{OD} settings in the Quartus II software Assignment Editor.

Figure 6-22: Differential V_{OD}

This figure shows the V_{OD} of the differential LVDS output.

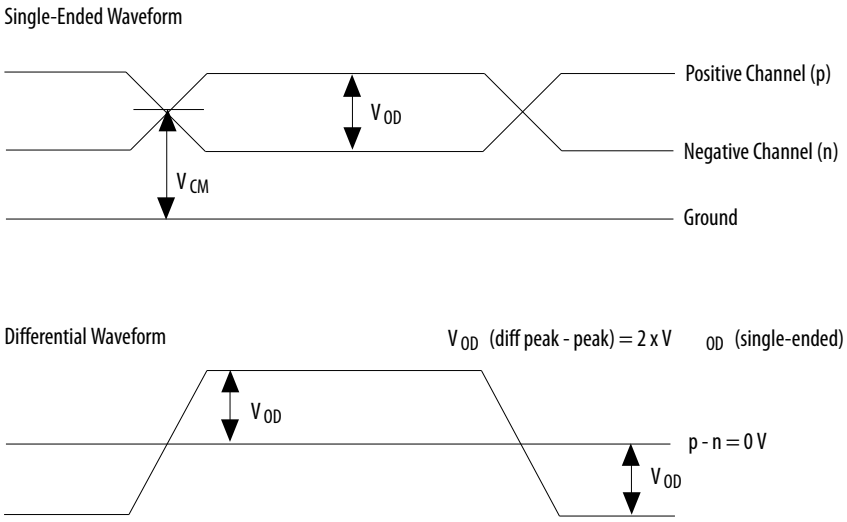


Table 6-9: Quartus II Software Assignment Editor—Programmable V_{OD}

This table lists the assignment name for programmable V_{OD} and its possible values in the Quartus II software Assignment Editor.

Field	Assignment
To	`tx_out`
Assignment name	Programmable Differential Output Voltage (V_{OD})
Allowed values	• Arria V GX, GT, SX, and ST—0 (low), 1 (medium), 2 (high). Default is 1. • Arria V GZ—0 (low), **1** (medium low), 2 (medium high), 3 (high). Default is 1.

Related Information

Programmable IOE Features in Arria V Devices on page 5-25

Programmable Pre-Emphasis

The V_{OD} setting and the output impedance of the driver set the output current limit of a high-speed transmission signal. At a high frequency, the slew rate may not be fast enough to reach the full V_{OD} level before the next edge, producing pattern-dependent jitter. With pre-emphasis, the output current is boosted momentarily during switching to increase the output slew rate.

Pre-emphasis increases the amplitude of the high-frequency component of the output signal, and thus helps to compensate for the frequency-dependent attenuation along the transmission line. The overshoot introduced by the extra current happens only during a change of state switching to increase the output slew rate and does not ring, unlike the overshoot caused by signal reflection. The amount of pre-emphasis required depends on the attenuation of the high-frequency component along the transmission line.

Figure 6-23: Programmable Pre-Emphasis

This figure shows the LVDS output with pre-emphasis.

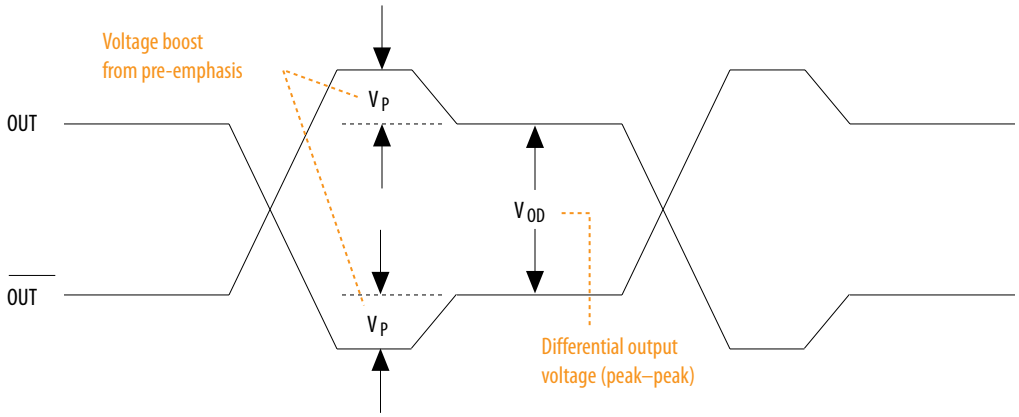

Table 6-10: Quartus II Software Assignment Editor—Programmable Pre-Emphasis

This table lists the assignment name for programmable pre-emphasis and its possible values in the Quartus II software Assignment Editor.

Field	Assignment
To	`tx_out`
Assignment name	Programmable Pre-emphasis
Allowed values	0 (disabled), 1 (enabled). Default is 1.

Programmable IOE Features in Arria V Devices on page 5-25

Differential Receiver in Arria V Devices

The receiver has a differential buffer and fractional PLLs that you can share among the transmitter and receiver, a DPA block, a synchronizer, a data realignment block, and a deserializer. The differential buffer can receive LVDS, mini-LVDS, and RSDS signal levels. You can statically set the I/O standard of the receiver pins to LVDS, mini-LVDS, or RSDS in the Quartus II software Assignment Editor.

Note: To drive the LVDS channels, you must use the PLLs in integer PLL mode.

Related Information

Guideline: Use PLLs in Integer PLL Mode for LVDS on page 6-7

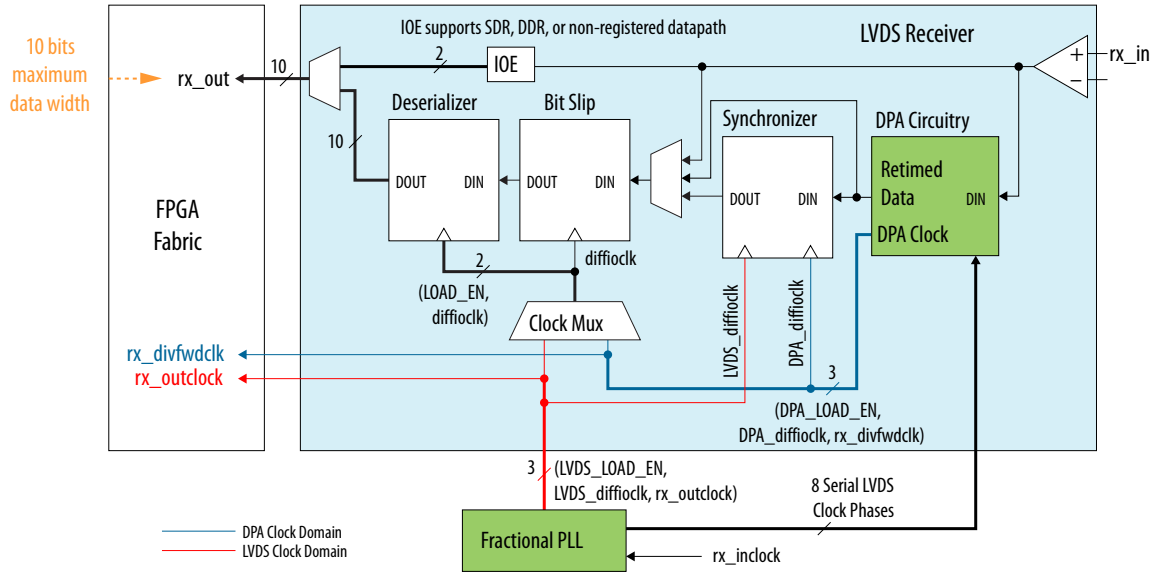
Receiver Blocks in Arria V Devices

The Arria V differential receiver has the following hardware blocks:

- DPA block
- Synchronizer
- Data realignment block (bit slip)
- Deserializer

The following figure shows the hardware blocks of the receiver. In SDR and DDR modes, the data width from the IOE is 1 and 2 bits, respectively. The deserializer includes shift registers and parallel load registers, and sends a maximum of 10 bits to the internal logic.

Figure 6-24: Receiver Block Diagram

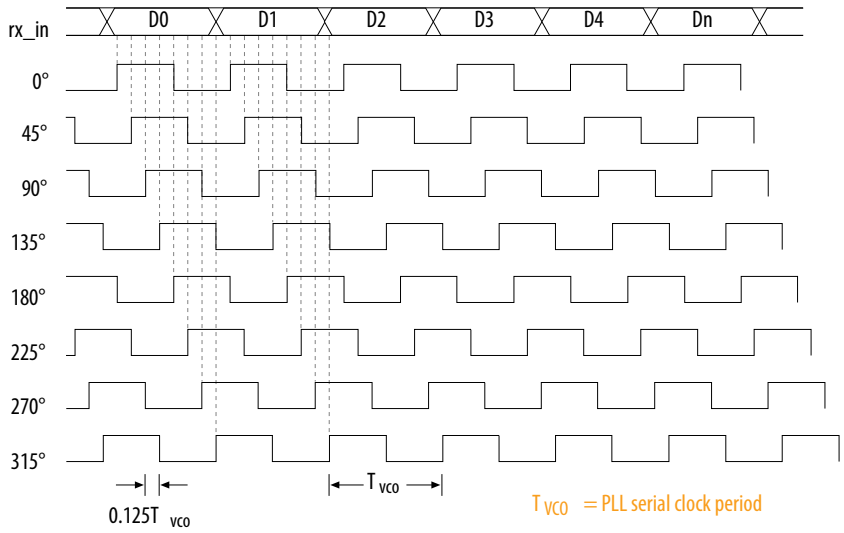


DPA Block

The DPA block takes in high-speed serial data from the differential input buffer and selects one of the eight phases that the fractional PLLs generate to sample the data. The DPA chooses a phase closest to the phase of the serial data. The maximum phase offset between the received data and the selected phase is 1/8 UI, which is the maximum quantization error of the DPA. The eight phases of the clock are equally divided, offering a 45° resolution.

The following figure shows the possible phase relationships between the DPA clocks and the incoming serial data.

Figure 6-25: DPA Clock Phase to Serial Data Timing Relationship



The DPA block continuously monitors the phase of the incoming serial data and selects a new clock phase if it is required. You can prevent the DPA from selecting a new clock phase by asserting the optional `RX_DPLL_HOLD` port, which is available for each channel.

DPA circuitry does not require a fixed training pattern to lock to the optimum phase out of the eight phases. After reset or power up, the DPA circuitry requires transitions on the received data to lock to the optimum phase. An optional output port, `RX_DPA_LOCKED`, is available to indicate an initial DPA lock condition to the optimum phase after power up or reset. This signal is not deasserted if the DPA selects a new phase out of the eight clock phases to sample the received data. Do not use the `rx_dpa_locked` signal to determine a DPA loss-of-lock condition. Use data checkers such as a cyclic redundancy check (CRC) or diagonal interleaved parity (DIP-4) to validate the data.

An independent reset port, `RX_RESET`, is available to reset the DPA circuitry. You must retrain the DPA circuitry after reset.

Note: The DPA block is bypassed in non-DPA mode.

Related Information

Guideline: Use PLLs in Integer PLL Mode for LVDS on page 6-7

Synchronizer

The synchronizer is a 1 bit wide and 6 bit deep FIFO buffer that compensates for the phase difference between `DPA_diffioclk`—the optimal clock that the DPA block selects—and the `LVDS_diffioclk` that the fractional PLLs produce. The synchronizer can only compensate for phase differences, not frequency differences, between the data and the receiver's input reference clock.

An optional port, `RX_FIFO_RESET`, is available to the internal logic to reset the synchronizer. The synchronizer is automatically reset when the DPA first locks to the incoming data. Altera recommends using `RX_FIFO_RESET` to reset the synchronizer when the data checker indicates that the received data is corrupted.

Note: The synchronizer circuit is bypassed in non-DPA and soft-CDR mode.

Related Information

Guideline: Use PLLs in Integer PLL Mode for LVDS on page 6-7

Data Realignment Block (Bit Slip)

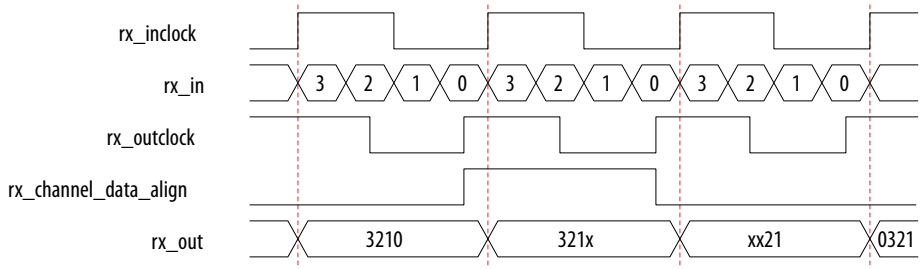
Skew in the transmitted data along with skew added by the link causes channel-to-channel skew on the received serial data streams. If you enable the DPA, the received data is captured with different clock phases on each channel. This difference may cause misalignment of the received data from channel to channel. To compensate for this channel-to-channel skew and establish the correct received word boundary at each channel, each receiver channel has a dedicated data realignment circuit that realigns the data by inserting bit latencies into the serial stream.

An optional `RX_CHANNEL_DATA_ALIGN` port controls the bit insertion of each receiver independently controlled from the internal logic. The data slips one bit on the rising edge of `RX_CHANNEL_DATA_ALIGN`. The requirements for the `RX_CHANNEL_DATA_ALIGN` signal include the following items:

- The minimum pulse width is one period of the parallel clock in the logic array.
- The minimum low time between pulses is one period of the parallel clock.
- The signal is an edge-triggered signal.
- The valid data is available two parallel clock cycles after the rising edge of `RX_CHANNEL_DATA_ALIGN`.

Figure 6-26: Data Realignment Timing

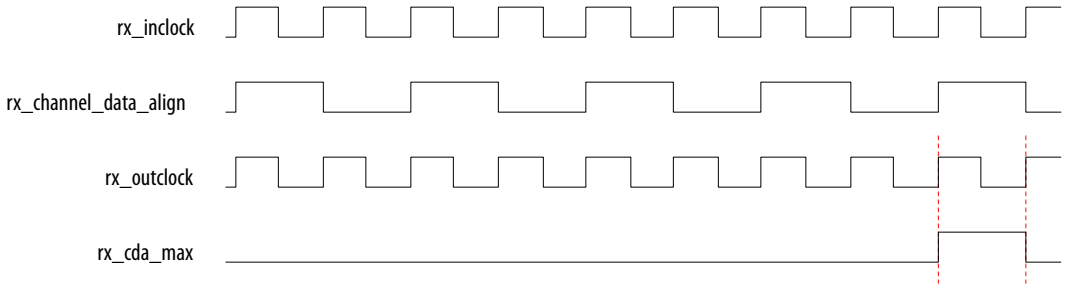
This figure shows receiver output (`RX_OUT`) after one bit slip pulse with the deserialization factor set to **4**.



The data realignment circuit can have up to 11 bit-times of insertion before a rollover occurs. The programmable bit rollover point can be from 1 to 11 bit-times, independent of the deserialization factor. Set the programmable bit rollover point equal to, or greater than, the deserialization factor—allowing enough depth in the word alignment circuit to slip through a full word. You can set the value of the bit rollover point using the MegaWizard Plug-In Manager. An optional status port, `RX_CDA_MAX`, is available to the FPGA fabric from each channel to indicate the reaching of the preset rollover point.

Figure 6-27: Receiver Data Realignment Rollover

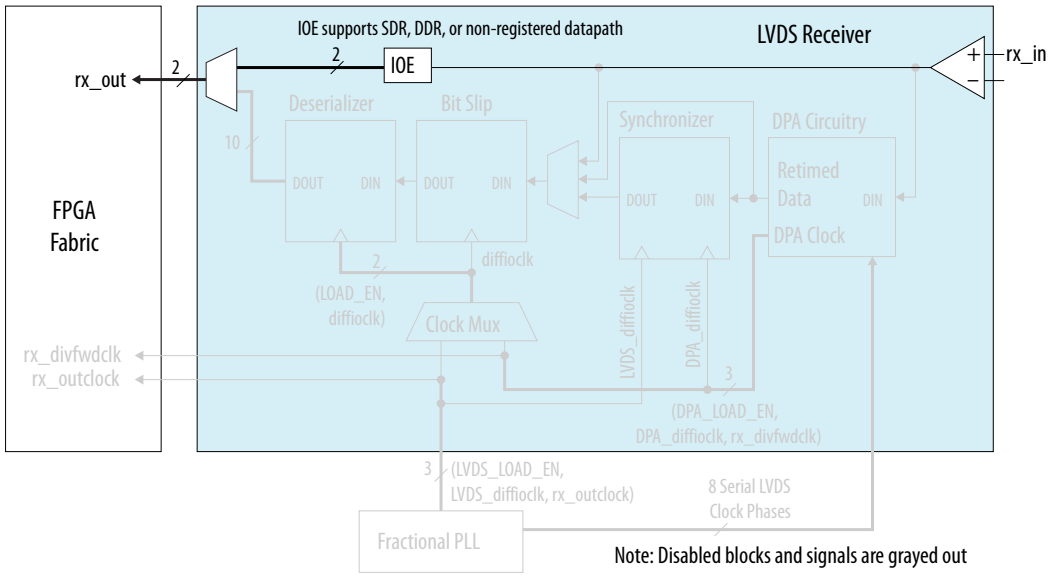
This figure shows a preset value of four bit-times before rollover occurs. The `rx_cda_max` signal pulses for one `rx_outclock` cycle to indicate that rollover has occurred.



Deserializer

You can statically set the deserialization factor to x3, x4, x5, x6, x7, x8, x9, or x10 by using the Quartus II software. You can bypass the deserializer in the Quartus II MegaWizard Plug-In Manager to support DDR (x2) or SDR (x1) operations, as shown in the following figure.

Figure 6-28: Deserializer Bypass



The IOE contains two data input registers that can operate in DDR or SDR mode. In DDR mode, `rx_inclock` clocks the IOE register. In SDR mode, data is directly passed through the IOE. In SDR and DDR modes, the data width from the IOE is 1 and 2 bits, respectively.

You cannot use the DPA and data realignment circuit when you bypass the deserializer.

Receiver Modes in Arria V Devices

The Arria V devices support the following receiver modes:

- Non-DPA mode
- DPA mode
- Soft-CDR mode

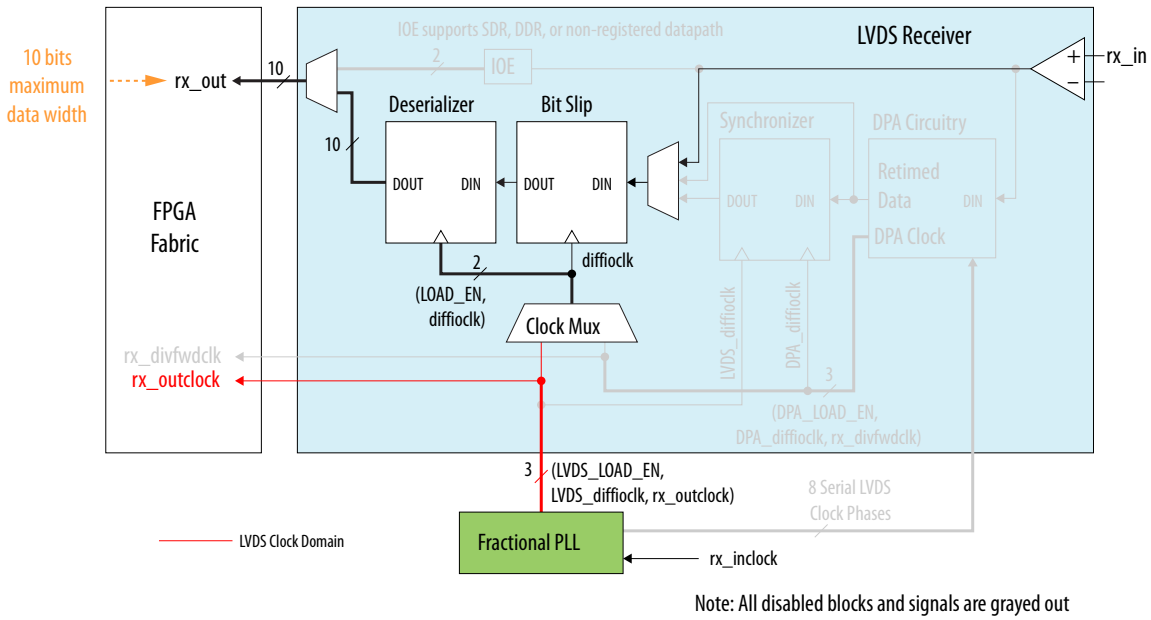
Non-DPA Mode

The non-DPA mode disables the DPA and synchronizer blocks. Input serial data is registered at the rising edge of the serial `LVDS_diffioclk` clock that is produced by the left and right PLLs.

You can select the rising edge option with the Quartus II MegaWizard Plug-In Manager. The `LVDS_diffioclk` clock that is generated by the left and right PLLs clocks the data realignment and deserializer blocks.

The following figure shows the non-DPA datapath block diagram. In SDR and DDR modes, the data width from the IOE is 1 and 2 bits, respectively.

Figure 6-29: Receiver Data Path in Non-DPA Mode



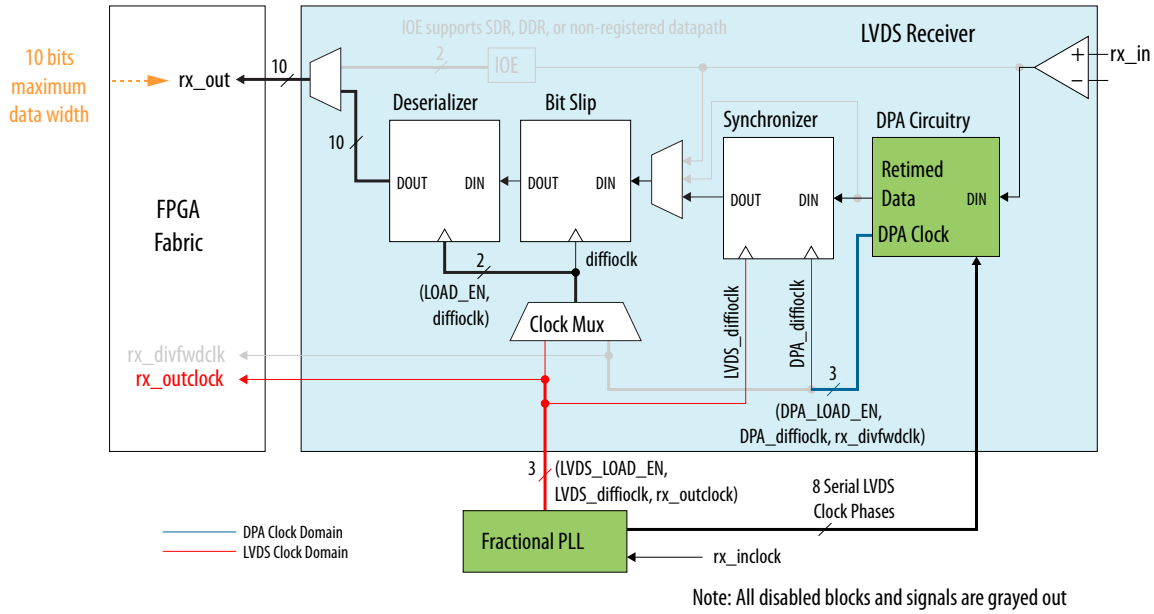
DPA Mode

The DPA block chooses the best possible clock (`DPA_diffioclk`) from the eight fast clocks that the fractional PLL sent. This serial `DPA_diffioclk` clock is used for writing the serial data into the synchronizer. A serial `LVDS_diffioclk` clock is used for reading the serial data from the synchronizer. The same `LVDS_diffioclk` clock is used in data realignment and deserializer blocks.

The following figure shows the DPA mode datapath. In the figure, all the receiver hardware blocks are active.

Figure 6-30: Receiver Datapath in DPA Mode

In SDR and DDR modes, the data width from the IOE is 1 and 2 bits, respectively.



Related Information

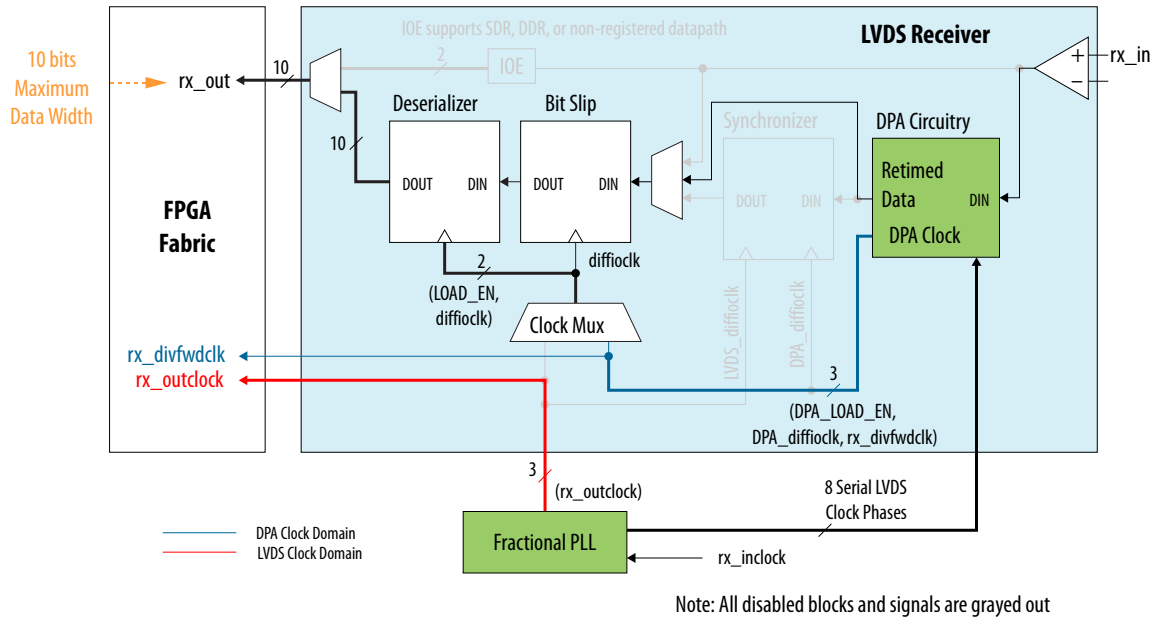
- **Guideline: Use PLLs in Integer PLL Mode for LVDS** on page 6-7
- **Receiver Blocks in Arria V Devices** on page 6-23

Soft-CDR Mode

The Arria V LVDS channel offers the soft-CDR mode to support the GbE and SGMII protocols. A receiver PLL uses the local clock source for reference.

The following figure shows the soft-CDR mode datapath. In SDR and DDR modes, the data width from the IOE is 1 and 2 bits, respectively.

Figure 6-31: Receiver Datapath in Soft-CDR Mode



In soft-CDR mode, the synchronizer block is inactive. The DPA circuitry selects an optimal DPA clock phase to sample the data. Use the selected DPA clock for bit-slip operation and deserialization. The DPA block also forwards the selected DPA clock, divided by the deserialization factor called `rx_divfwdclk`, to the FPGA fabric, along with the deserialized data. This clock signal is put on the periphery clock (PCLK) network.

If you use the soft-CDR mode, do not assert the `rx_reset` port after the DPA has trained. The DPA continuously chooses new phase taps from the PLL to track parts per million (PPM) differences between the reference clock and incoming data.

You can use every LVDS channel in soft-CDR mode and drive the FPGA fabric using the PCLK network in the Arria V device family. The `rx_dpa_locked` signal is not valid in soft-CDR mode because the DPA continuously changes its phase to track PPM differences between the upstream transmitter and the local receiver input reference clocks. The parallel clock, `rx_outclock`, generated by the left and right PLLs, is also forwarded to the FPGA fabric.

Related Information

Periphery Clock Networks on page 4-5
Provides more information about PCLK networks.

Receiver Clocking for Arria V Devices

The fractional PLL receives the external clock input and generates different phases of the same clock. The DPA block automatically chooses one of the clocks from the fractional PLL and aligns the incoming data on each channel.

The synchronizer circuit is a 1 bit wide by 6 bit deep FIFO buffer that compensates for any phase difference between the DPA clock and the data realignment block. If necessary, the user-controlled data realignment circuitry inserts a single bit of latency in the serial bit stream to align to the word boundary.

The physical medium connecting the transmitter and receiver LVDS channels may introduce skew between the serial data and the source-synchronous clock. The instantaneous skew between each LVDS channel and the clock also varies with the jitter on the data and clock signals as seen by the receiver. The three different modes—non-DPA, DPA, and soft-CDR—provide different options to overcome skew between the source synchronous clock (non-DPA, DPA) /reference clock (soft-CDR) and the serial data.

Non-DPA mode allows you to statically select the optimal phase between the source synchronous clock and the received serial data to compensate skew. In DPA mode, the DPA circuitry automatically chooses the best phase to compensate for the skew between the source synchronous clock and the received serial data. Soft-CDR mode provides opportunities for synchronous and asynchronous applications for chip-to-chip and short reach board-to-board applications for SGMII protocols.

Note: Only the non-DPA mode requires manual skew adjustment.

Guideline: Use PLLs in Integer PLL Mode for LVDS on page 6-7

Differential I/O Termination for Arria V Devices

The Arria V devices provide a 100 Ω, on-chip differential termination option on each differential receiver channel for LVDS standards. On-chip termination saves board space by eliminating the need to add external resistors on the board. You can enable on-chip termination in the Quartus II software Assignment Editor.

All I/O pins and dedicated clock input pins support on-chip differential termination, R_D OCT.

Figure 6-32: On-Chip Differential I/O Termination

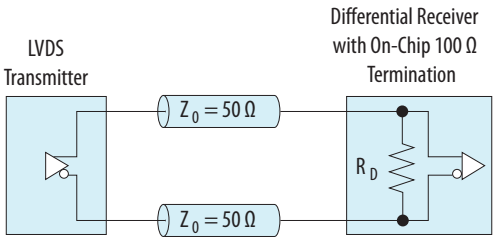

Table 6-11: Quartus II Software Assignment Editor—On-Chip Differential Termination

This table lists the assignment name for on-chip differential termination in the Quartus II software Assignment Editor.

Field	Assignment
To	`rx_in`
Assignment name	Input Termination
Value	Differential

Source-Synchronous Timing Budget

The topics in this section describe the timing budget, waveforms, and specifications for source-synchronous signaling in the Arria V device family.

The LVDS I/O standard enables high-speed transmission of data, resulting in better overall system performance. To take advantage of fast system performance, you must analyze the timing for these high-speed signals. Timing analysis for the differential block is different from traditional synchronous timing analysis techniques.

The basis of the source synchronous timing analysis is the skew between the data and the clock signals instead of the clock-to-output setup times. High-speed differential data transmission requires the use of timing parameters provided by IC vendors and is strongly influenced by board skew, cable skew, and clock jitter.

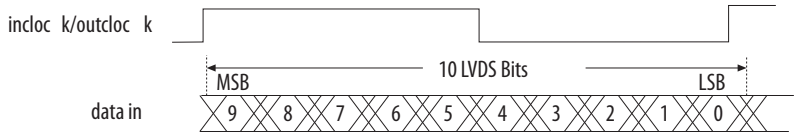
This section defines the source-synchronous differential data orientation timing parameters, the timing budget definitions for the Arria V device family, and how to use these timing parameters to determine the maximum performance of a design.

Differential Data Orientation

There is a set relationship between an external clock and the incoming data. For operations at 1 Gbps and a serialization factor of 10, the external clock is multiplied by 10. You can set phase-alignment in the PLL to coincide with the sampling window of each data bit. The data is sampled on the falling edge of the multiplied clock.

Figure 6-33: Bit Orientation in the Quartus II Software

This figure shows the data bit orientation of the x10 mode.



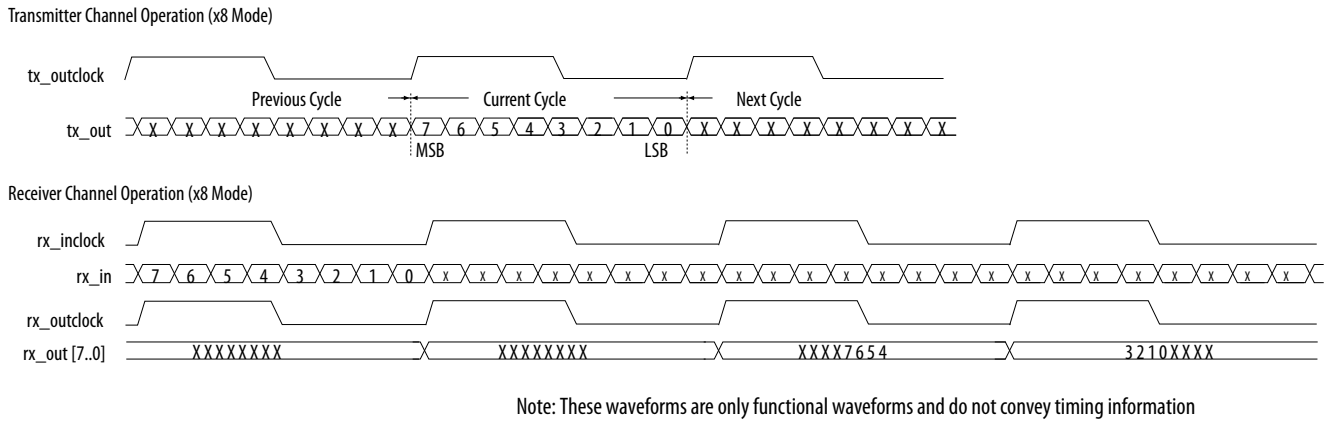
Differential I/O Bit Position

Data synchronization is necessary for successful data transmission at high frequencies.

The following figure shows the data bit orientation for a channel operation and is based on the following conditions:

- The serialization factor is equal to the clock multiplication factor.
- The phase alignment uses edge alignment.
- The operation is implemented in hard SERDES.

Figure 6-34: Bit-Order and Word Boundary for One Differential Channel



Note: These waveforms are only functional waveforms and do not convey timing information

For other serialization factors, use the Quartus II software tools to find the bit position within the word.

Differential Bit Naming Conventions

The following table lists the conventions for differential bit naming for 18 differential channels. The MSB and LSB positions increase with the number of channels used in a system.

Table 6-12: Differential Bit Naming

This table lists the conventions for differential bit naming for 18 differential channels. The MSB and LSB positions increase with the number of channels used in a system.

Receiver Channel Data Number	Internal 8-Bit Parallel Data	
	MSB Position	LSB Position
1	7	0
2	15	8
3	23	16
4	31	24
5	39	32
6	47	40
7	55	48
8	63	56
9	71	64
10	79	72
11	87	80
12	95	88
13	103	96
14	111	104

Receiver Channel Data Number	Internal 8-Bit Parallel Data	
	MSB Position	LSB Position
15	119	112
16	127	120
17	135	128
18	143	136

Transmitter Channel-to-Channel Skew

The receiver skew margin calculation uses the transmitter channel-to-channel skew (TCCS)—an important parameter based on the Arria V transmitter in a source-synchronous differential interface:

- TCCS is the difference between the fastest and slowest data output transitions, including the T_{CO} variation and clock skew.
- For LVDS transmitters, the TimeQuest Timing Analyzer provides the TCCS value in the TCCS report (`report_TCCS`) in the Quartus II compilation report, which shows TCCS values for serial output ports.
- You can also get the TCCS value from the device datasheet.

Note: For the Arria V GZ devices, perform PCB trace compensation to adjust the trace length of each LVDS channel to improve channel-to-channel skew when interfacing with non-DPA receivers at data rate above 840 Mbps.

The Quartus II software Fitter Report panel reports the amount of delay you must add to each trace for the Arria V device. You can use the recommended trace delay numbers published under the LVDS Transmitter/Receiver Package Skew Compensation panel and manually compensate the skew on the PCB board trace to reduce channel-to-channel skew, thus meeting the timing budget between LVDS channels.

  More information about the LVDS Transmitter/Receiver Package Skew Compensation report panel.

Receiver Skew Margin for Non-DPA Mode

Different modes of LVDS receivers use different specifications, which can help in deciding the ability to sample the received serial data correctly:

- In DPA mode, use DPA jitter tolerance instead of the receiver skew margin (RSKM).
- In non-DPA mode, use RSKM, TCCS, and sampling window (SW) specifications for high-speed source-synchronous differential signals in the receiver data path.

The following equation expresses the relationship between RSKM, TCCS, and SW.

Figure 6-35: RSKM Equation

$$RSKM = \frac{TUI - SW - TCCS}{2}$$

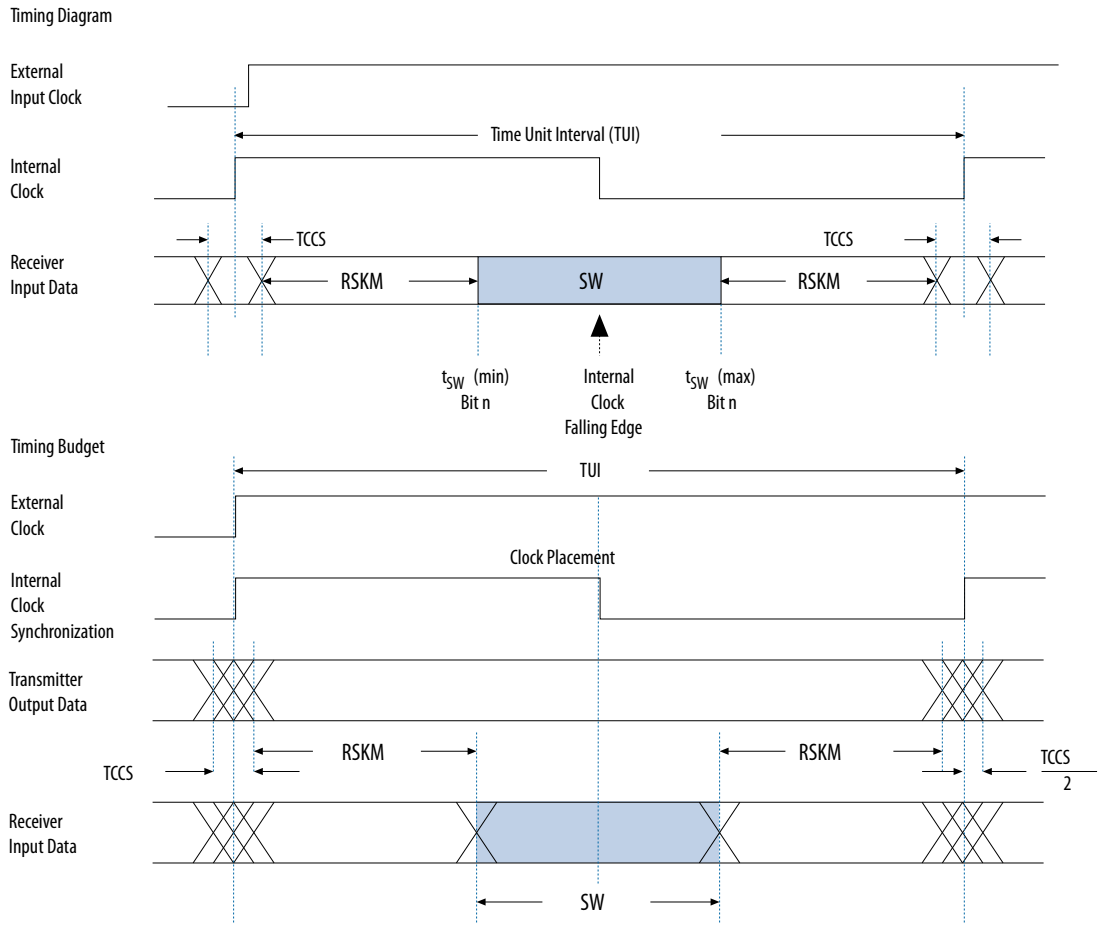
Conventions used for the equation:

- RSKM—the timing margin between the receiver's clock input and the data input sampling window.
- Time unit interval (TUI)—time period of the serial data.
- SW—the period of time that the input data must be stable to ensure that data is successfully sampled by the LVDS receiver. The SW is a device property and varies with device speed grade.
- TCCS—the timing difference between the fastest and the slowest output edges, including t_{CO} variation and clock skew, across channels driven by the same PLL. The clock is included in the TCCS measurement.

You must calculate the RSKM value to decide whether the LVDS receiver can sample the data properly or not, given the data rate and device. A positive RSKM value indicates that the LVDS receiver can sample the data properly, whereas a negative RSKM indicates that it cannot sample the data properly.

The following figure shows the relationship between the RSKM, TCCS, and the SW of the receiver.

Figure 6-36: Differential High-Speed Timing Diagram and Timing Budget for Non-DPA Mode



For LVDS receivers, the Quartus II software provides an RSKM report showing the SW, TUI, and RSKM values for non-DPA LVDS mode:

- You can generate the RSKM report by executing the `report_RSKM` command in the TimeQuest Timing Analyzer. You can find the RSKM report in the Quartus II compilation report in the TimeQuest Timing Analyzer section.
- To obtain the RSKM value, assign the input delay to the LVDS receiver through the constraints menu of the TimeQuest Timing Analyzer. The input delay is determined according to the data arrival time at the LVDS receiver port, with respect to the reference clock.
- If you set the input delay in the settings parameters for the **Set Input Delay** option, set the clock name to the clock that reference the source synchronous clock that feeds the LVDS receiver.
- If you do not set any input delay in the TimeQuest Timing Analyzer, the receiver channel-to-channel skew defaults to zero.
- You can also directly set the input delay in a Synopsys Design Constraint file (**.sdc**) using the `set_input_delay` command.

  Provides more information about **.sdc** commands and the TimeQuest Timing Analyzer.

Assigning Input Delay to LVDS Receiver Using TimeQuest Timing Analyzer

To obtain the RSKM value, assign an appropriate input delay to the LVDS receiver from the TimeQuest Timing Analyzer constraints menu.

1. On the menu in the TimeQuest Timing Analyzer, select **Constraints** > **Set Input Delay**.
2. In the **Set Input Delay** window, select the desired clock using the pull-down menu. The clock name must reference the source synchronous clock that feeds the LVDS receiver.
3. Click the **Browse** button (next to the **Targets** field).
4. In the **Name Finder** window, click **List** to view a list of all available ports. Select the LVDS receiver serial input ports according to the input delay you set, and click **OK**.
5. In the **Set Input Delay** window, set the appropriate values in the **Input delay** options and **Delay value** fields.
6. Click **Run** to incorporate these values in the TimeQuest Timing Analyzer.
7. Repeat from **step 1** to assign the appropriate delay for all the LVDS receiver input ports. If you have already assigned Input Delay and you need to add more delay to that input port, turn on the **Add Delay** option.

Document Revision History

Date	Version	Changes
January 2015	2015.01.19	• Removed statement on explanation related to rx_synclock for figure "LVDS Interface with the Altera_PLL Megafunction (With Soft-CDR Mode)". • Updated figure LVDS Interface with the Altera_PLL Megafunction (With Soft-CDR Mode) and figure Receiver Datapath in Soft-CDR Mode. • Added a note to leave rx_enable and rx_inclock to be unconnected for figure LVDS Interface with the Altera_PLL Megafunction (With Soft-CDR Mode). • Updated timing diagram for Phase Relationship for External PLL Interface Signals to reflect the correct phase shift and frequency for outclk2.

Date	Version	Changes
January 2014	2014.01.10	• Updated the statement about setting the phase of the clock in relation to data in the topic about transmitter clocking. • Added a figure that shows the phase relationship for the external PLL interface signals. • Clarified that "one row of separation" between two groups of DPA-enabled channels means a separation of one differential channel. • Clarified that "internal PLL option" refers to the option in the ALTLVDS megafunction. • Updated the topic about emulated LVDS buffers to clarify that you can use unutilized true LVDS input channels (instead "buffers") as emulated LVDS output buffers.
August 2013	2013.08.19	Updated the number of LVDS channels of the Arria V GZ E5 and E7 devices (1517-pin package) from 80 to 79 (top banks TX) and 82 to 81 (top banks RX).
June 2013	2013.06.21	Updated the figure about data realignment timing to correct the data pattern after a bit slip.
May 2013	2013.05.06	• Moved all links to the Related Information section of respective topics for easy reference. • Added link to the known document issues in the Knowledge Base. • Clarified that the clock tree network cannot cross over to different I/O regions only applies to Arria V GZ. • Added a figure to show the center PLLs driving the DPA-enabled differential I/Os in Arria V GZ devices. • Changed the color of the transceiver blocks in the high-speed differential I/O location diagrams for clarity. • Reorganized contents under the differential receiver topic. • Added a topic about emulated LVDS buffers. • Edited the topic about true LVDS buffers. • Corrected references to upper and lower I/O banks to left and right I/O banks, respectively. • Updated the data realignment timing figure to improve clarity. • Updated the receiver data realignment rollover figure to improve clarity.

Date	Version	Changes
November 2012	2012.11.19	• Reorganized content and updated template. • Added Arria V GZ information. • Added Altera_PLL settings for external PLL usage in DPA and non-DPA modes. • Updated clocking examples. Altera_PLL now supports entering negative phase shift. • Rearranged the LVDS channel counts table into several tables according to device variant for ease of reference. • Updated the Arria V GX A1 and A3 LVDS channel counts, and added the channel counts for Arria V GZ. • Removed references to ALTPLL and added information about Altera_PLL. Altera_PLL now replaces ALTPLL for Arria V devices. • Added design guidelines for using LVDS interface with the external PLL mode. These include information on the signal interfaces, the parameter values, and the connection between Altera_PLL and ALTLVDS in external PLL mode. • Updated the programmable V_{OD} allowed values for Arria V GX, GT, SX, and ST, and added the values for Arria V GZ. • Moved the PLL and clocking section into design guideline topics. • Added steps to assign input delay to LVDS receiver using the TimeQuest Timing Analyzer.
June 2012	2.0	• Restructured the chapter. • Updated Table 6–1. • Updated Figure 6–1 and Figure 6–2. • Added Figure 6–3. • Added “Design Considerations” section. • Updated the “Differential Pin Placement” section.
November 2011	1.1	• Updated Table 6–1. • Restructured chapter.
May 2011	1.0	Initial release.

External Memory Interfaces in Arria V Devices

7

2015.01.23

AV-52007 Subscribe Send Feedback

The Arria V devices provide an efficient architecture that allows you to fit wide external memory interfaces to support a high level of system bandwidth within the small modular I/O bank structure. The I/Os are designed to provide high-performance support for existing and emerging external memory standards.

Table 7-1: Supported External Memory Standards in Arria V Devices

Memory Standard	Hard Memory Controller	Soft Memory Controller	
	Arria V GX, GT, SX, and ST	Arria V GX, GT, SX, and ST	Arria V GZ
DDR3 SDRAM	Full rate	Half rate and quarter rate	Half rate and quarter rate
DDR2 SDRAM	Full rate	Half rate	Full rate and half rate
LPDDR2 SDRAM	—	Half rate	—
RLDRAM 3	—	—	Half rate and quarter rate
RLDRAM II	—	Half rate	Full rate and half rate
QDR II+ SRAM	—	Half rate	Full rate and half rate
QDR II SRAM	—	Half rate	Full rate and half rate

Memory Interface Pin Support in Arria V Devices

In the Arria V devices, the memory interface circuitry is available in every I/O bank that does not support transceivers. The devices offer differential input buffers for differential read-data strobe and clock operations.

The memory clock pins are generated with double data rate input/output (DDRIO) registers.

Related Information

Planning Pin and FPGA Resources chapter, External Memory Interface Handbook
Provides more information about which pins to use for memory clock pins and pin location requirements.

Guideline: Using DQ/DQS Pins

The following list provides guidelines on using the DQ/DQS pins:

- The devices support DQ and DQS signals with DQ bus modes of x4/x8/x9, x16/x18, or x32/x36.
- You can use the DQSn or CQn pins that are not used for clocking as DQ pins.
- If you do not use the DQ/DQS pins for memory interfacing, you can use these pins as user I/Os. However, unused HPS DQ/DQS pins on the Arria V SX and ST devices cannot be used as user I/Os.
- Some pins have multiple functions such as RZQ or DQ. If you need extra RZQ pins, you can use some of the DQ pins as RZQ pins instead.

Note: For the x8, x16/x18, or x32/x36 DQ/DQS groups whose members are used as RZQ pins, Altera recommends that you assign the DQ and DQS pins manually. Otherwise, the Quartus II software might not be able to place the DQ and DQS pins, resulting in a "no-fit" error.

Reading the Pin Table

For the maximum number of DQ pins and the exact number per group for a particular Arria V device, refer to the relevant device pin table.

In the pin tables, the DQS and DQSn pins denote the differential data strobe/clock pin pairs, while the CQ and CQn pins denote the complementary echo clock signals. The pin table lists the parity, DM, BWSn, NWSn, ECC, and QVLD pins as DQ pins.

DQ/DQS Bus Mode Pins for Arria V Devices

The following tables list the pin support per DQ/DQS bus mode, including the DQS/CQ/CQn/QK# and DQSn pins. The maximum number of data pins per group listed in the tables may vary according to the following conditions:

- Single-ended DQS signaling—the maximum number of DQ pins includes parity, data mask, and QVLD pins connected to the DQS bus network.
- Differential or complementary DQS signaling—the maximum number of data pins per group decreases by one. This number may vary per DQ/DQS group in a particular device. Check the pin table for the exact number per group.
- DDR3 and DDR2 interfaces—the maximum number of pins is further reduced for an interface larger than x8 because you require one DQS pin for each x8/x9 group to form the x16/x18 and x32/x36 groups.

Table 7-4: DQ/DQS Bus Mode Pins for Arria V GX, GT, SX, and ST Devices

Mode	DQSn Support	CQn Support	Parity or Data Mask (Optional)	QVLD [19] (Optional)	Data Pins per Group		Notes
					Typical	Maximum	
x4/x8/x9	Yes	Yes	Yes	Yes	4, 8, or 9	11	The x4 mode uses x8/x9 groups.
x16/x18	Yes	Yes	Yes	Yes	16 or 18	23	Two x8 DQ/DQS groups are stitched to create a x16/x18 group, so there are 24 pins in this group.
x32/x36	Yes	Yes	Yes	Yes	32 or 36	47	Four x8 DQ/DQS groups are stitched to create a x32/x36 group, so there are 48 pins in this group.

Table 7-5: DQ/DQS Bus Mode Pins for Arria V GZ Devices

Mode	DQSn Support	CQn Support	Parity or Data Mask (Optional)	QVLD [19] (Optional)	Data Pins per Group		Notes
					Typical	Maximum	
x4	Yes	—	—	—	4	5	If you do not use differential DQS and the group does not have additional signals, the data mask (DM) pin is supported.
x8/x9	Yes	Yes	Yes	Yes	8 or 9	11	Two x4 DQ/DQS groups are stitched to create a x8/x9 group, so there are a total of 12 pins in this group.

[19] The QVLD pin is not used in the UniPHY megafunction.

Mode	DQSn Support	CQn Support	Parity or Data Mask (Optional)	QVLD [19] (Optional)	Data Pins per Group		Notes
					Typical	Maximum	
x16/x18	Yes	Yes	Yes	Yes	16 or 18	23	Four x4 DQ/DQS groups are stitched to create a x16/x18 group; so there are a total of 24 pins in this group.
x32/x36	Yes	Yes	Yes	Yes	32 or 36	47	Eight x4 DQ/DQS groups are stitched to create a x32/x36 group, so there are a total of 48 pins in this group.

External Memory Interface Features in Arria V Devices

The Arria V I/O elements (IOE) provide built-in functionality required for a rapid and robust implementation of external memory interfacing.

The following device features are available for external memory interfaces:

- DQS phase-shift circuitry
- PHY Clock (PHYCLK) networks
- DQS logic block
- Dynamic on-chip termination (OCT) control
- IOE registers
- Delay chains
- Hard memory controllers (Arria V GX, GT, SX, and ST only)
- Read- and write-leveling support (Arria V GZ only)

UniPHY IP

The high-performance memory interface solution includes the self-calibrating UniPHY IP that is optimized to take advantage of the Arria V I/O structure and the Quartus II software TimeQuest Timing Analyzer. The UniPHY IP helps set up the physical interface (PHY) best suited for your system. This provides the total solution for the highest reliable frequency of operation across process, voltage, and temperature (PVT) variations.

The UniPHY IP instantiates a PLL to generate related clocks for the memory interface. The UniPHY IP can also dynamically choose the number of delay chains that are required for the system. The amount of delay is equal to the sum of the intrinsic delay of the delay element and the product of the number of delay steps and the value of the delay steps.

The UniPHY IP and the Altera memory controller MegaCore® functions can run at half the I/O interface frequency of the memory devices, allowing better timing management in high-speed memory interfaces. The Arria V devices contain built-in circuitry in the IOE to convert data from full rate (the I/O frequency) to half rate (the controller frequency) and vice versa.

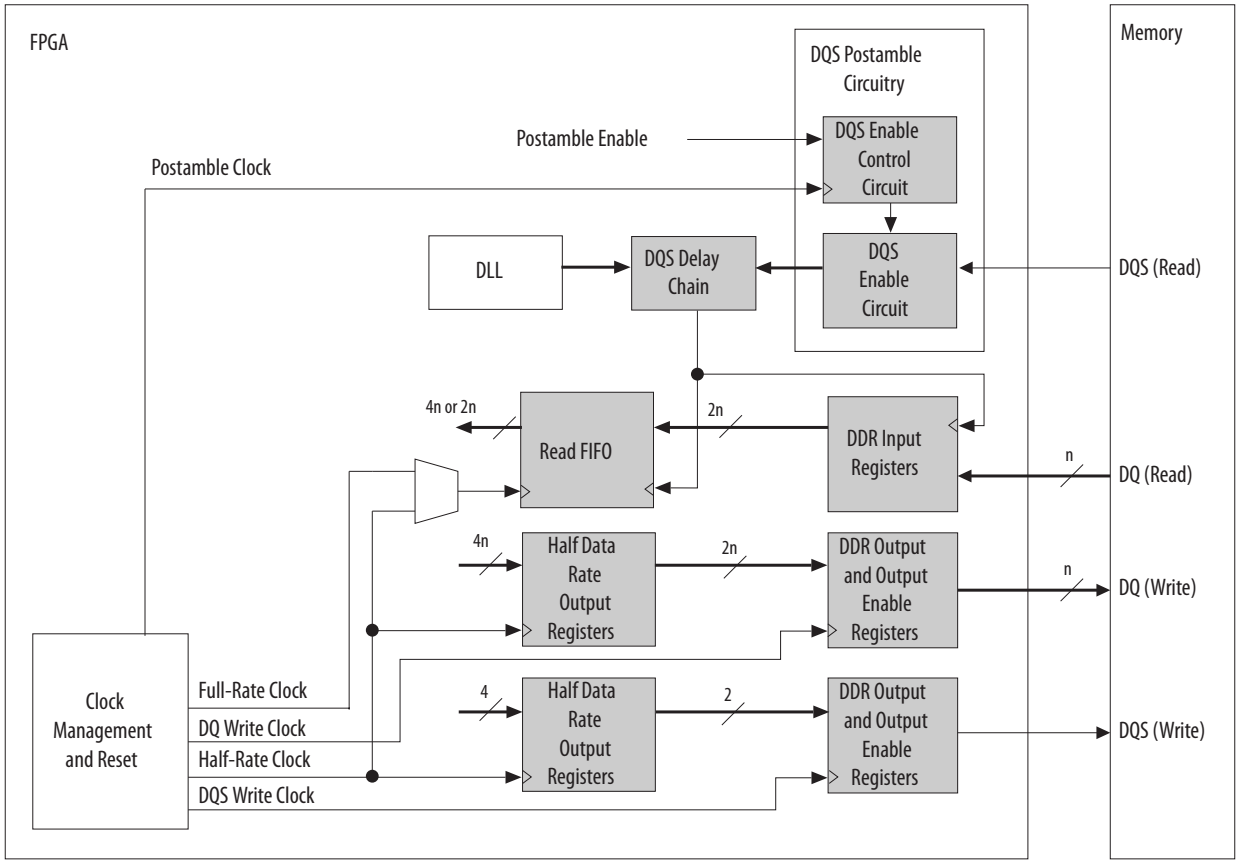
Related Information

Reference Material volume, External Memory Interface Handbook
Provides more information about the UniPHY IP.

External Memory Interface Datapath

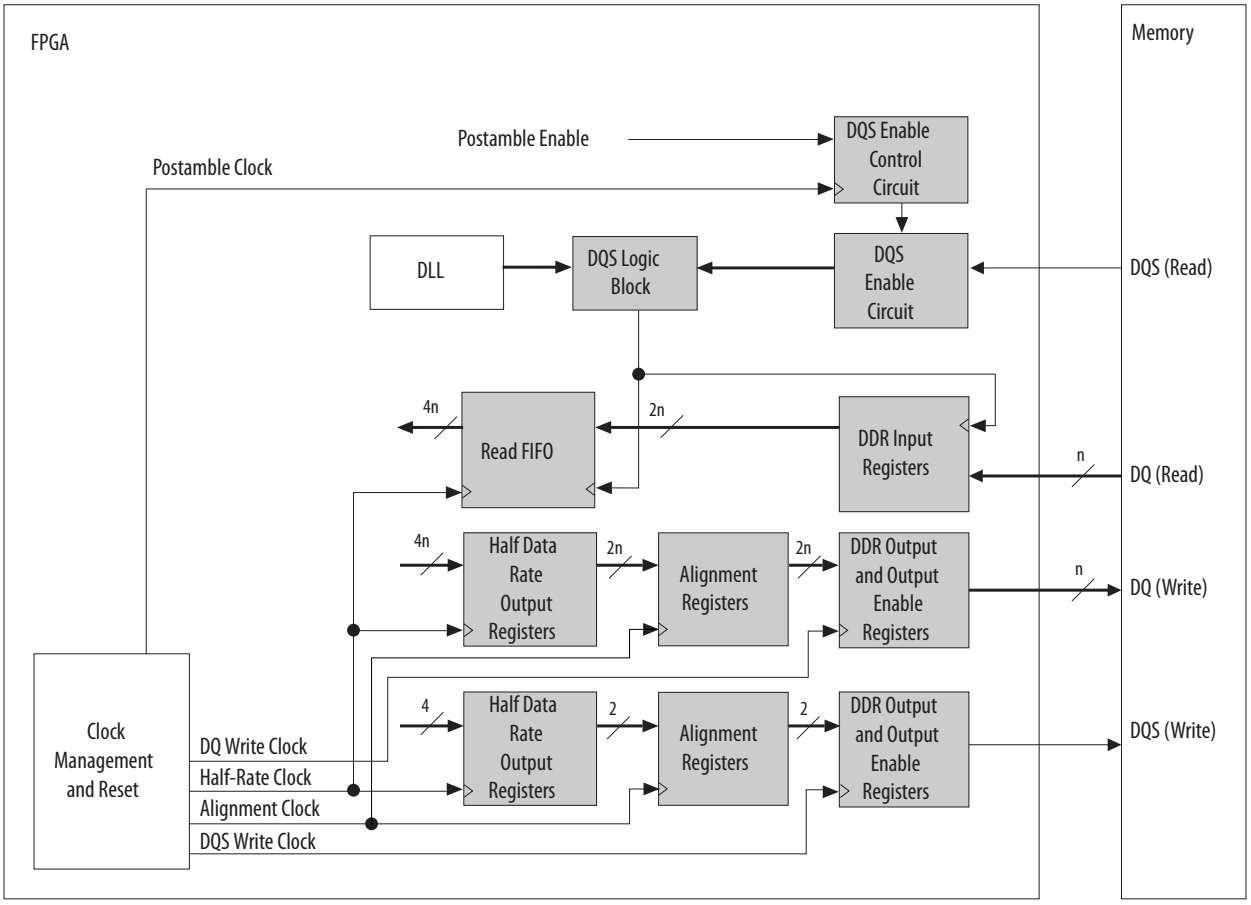
The following figures show overviews of the memory interface datapath that uses the Arria V I/O elements. In the figures, the DQ/DQS read and write signals may be bidirectional or unidirectional, depending on the memory standard. If the signal is bidirectional, it is active during read and write operations.

Figure 7-1: External Memory Interface Datapath Overview for Arria V GX, GT, SX, and ST Devices



Note: There are slight block differences for different memory interface standards. The shaded blocks are part of the I/O elements.

Figure 7-2: External Memory Interface Datapath Overview for Arria V GZ Devices



Note: There are slight block differences for different memory interface standards. The shaded blocks are part of the I/O elements.

DQS Phase-Shift Circuitry

The Arria V DLL provides phase shift to the DQS/CQ/CQn/QK# pins on read transactions if the DQS/CQ/CQn/QK# pins are acting as input clocks or strobes to the FPGA.

The following figures show how the DLLs are connected to the DQS/CQ/CQn/QK# pins in the various Arria V variants.

Figure 7-3: DQS/CQ/CQn/QK# Pins and DLLs in Arria V GX (A1 and A3) Devices

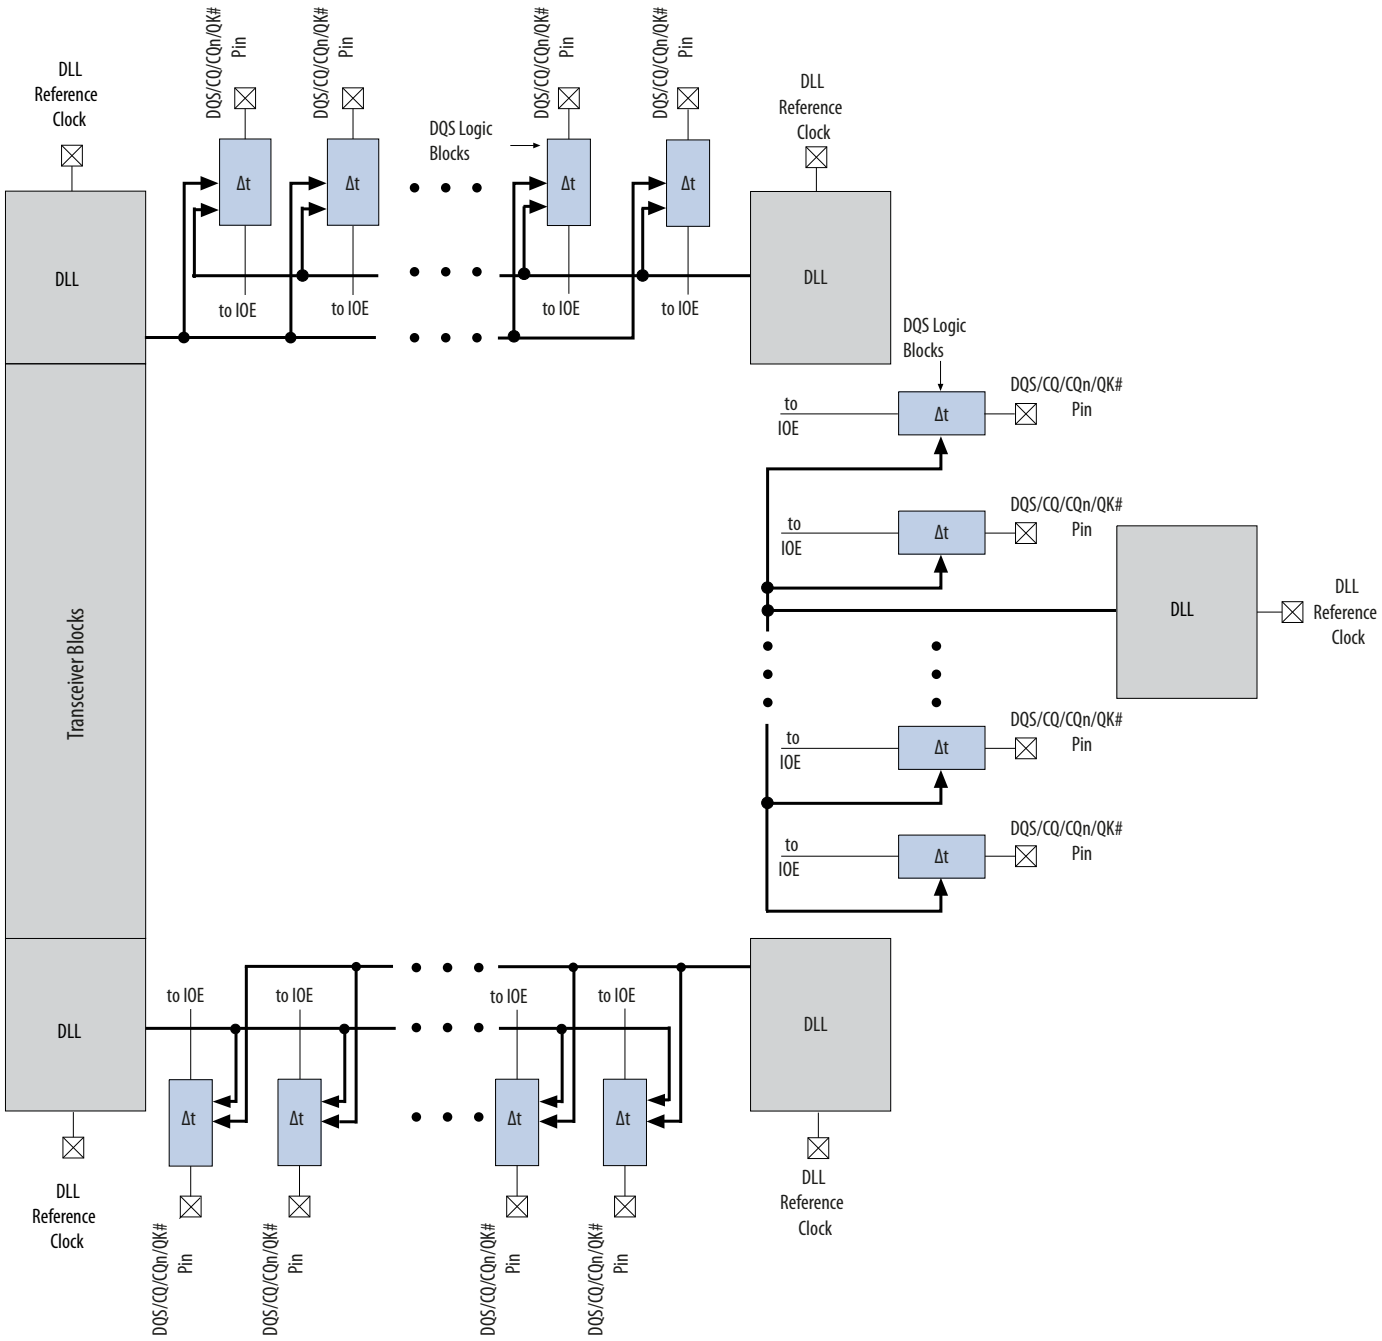


Figure 7-4: DQS/CQ/CQn/QK# Pins and DLLs in Arria V GX (A5, A7, B1, B3, B5, and B7), GT, and GZ Devices

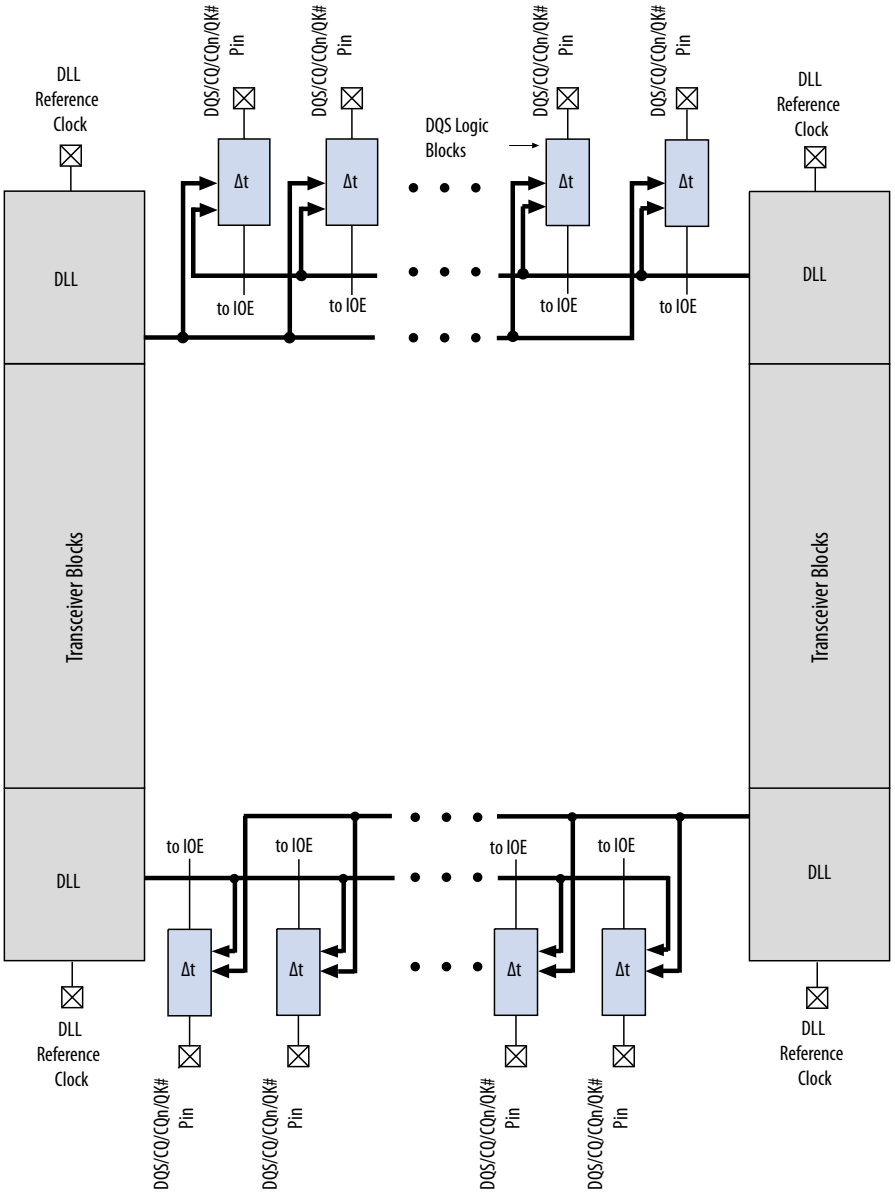

Figure 7-5: DQS/CQ/CQn/QK# Pins and DLLs in Arria V SX and ST Devices

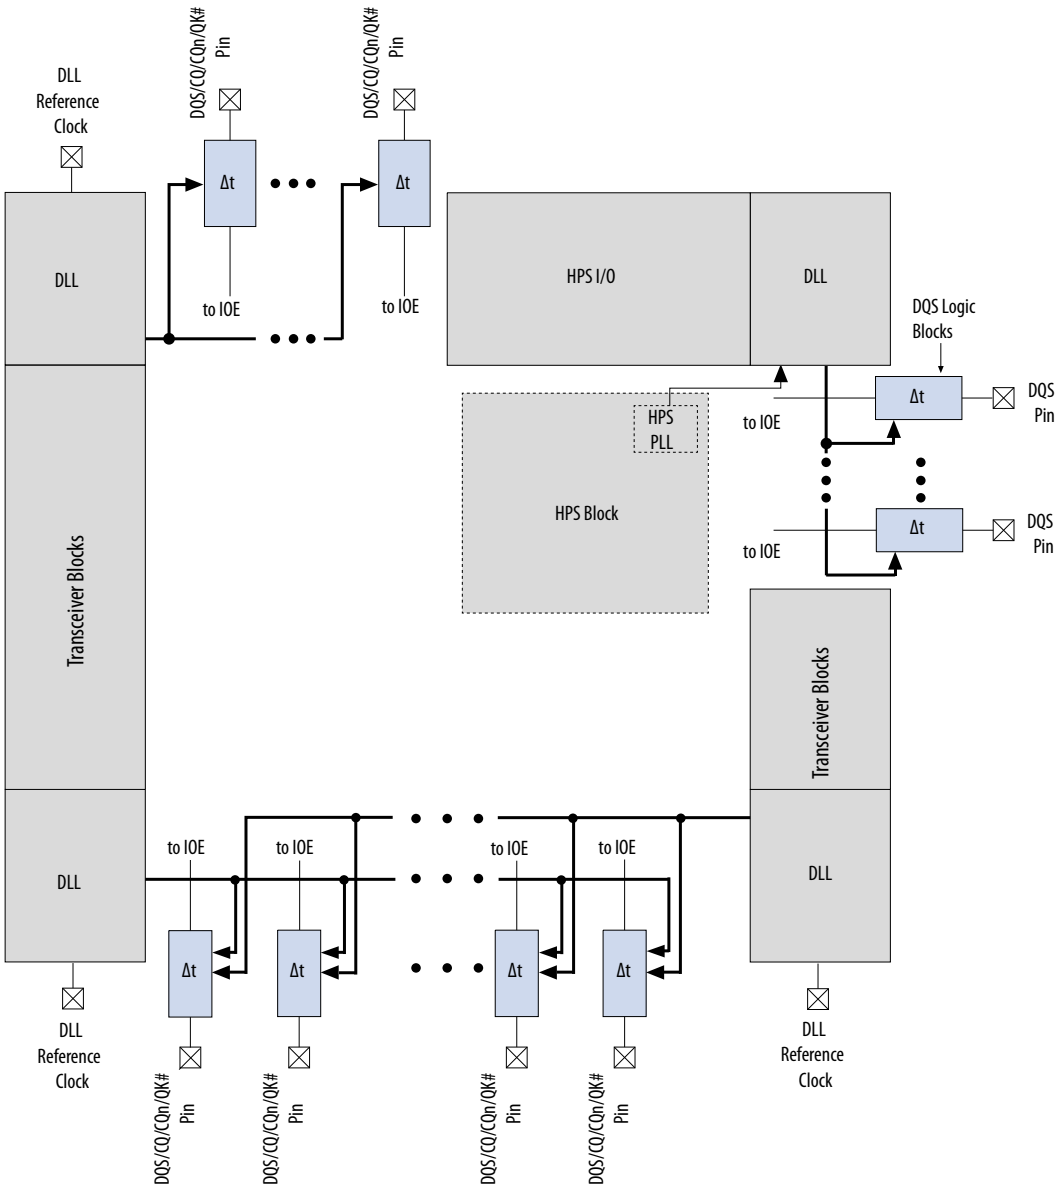

Delay-Locked Loop

The delay-locked loop (DLL) uses a frequency reference to dynamically generate control signals for the delay chains in each of the DQS/CQ/CQn/QK# pins, allowing the delay to compensate for process, voltage, and temperature (PVT) variations. The DQS delay settings are gray-coded to reduce jitter if the DLL updates the settings.

There are a maximum of five DLLs in Arria V devices. You can clock each DLL using different frequencies.

Some of the DLLs can access the two adjacent sides from its location in the device. You can have two different interfaces with the same frequency on the two sides adjacent to a DLL, where the DLL controls the DQS delay settings for both interfaces.

I/O banks between two DLLs have the flexibility to create multiple frequencies and multiple-type interfaces. These banks can use settings from either or both adjacent DLLs. For example, DQS1R can get its phase-shift settings from DLL_TR, while DQS2R can get its phase-shift settings from DLL_BR.

The reference clock for each DLL may come from the PLL output clocks or clock input pins.

Note: If you have a dedicated PLL that only generates the DLL input reference clock, set the PLL mode to **No Compensation** to achieve better performance (or the Quartus II software automatically changes it). Because the PLL does not use any other outputs, it does not have to compensate for any clock paths.

DLL Reference Clock Input for Arria V Devices

DLL Phase-Shift

The DLL can shift the incoming DQS signals by 0° or 90° by using two delay cells in the DQS logic block. The shifted DQS signal is then used as the clock for the DQ IOE input registers.

All DQS/CQ/CQn/QK# pins referenced to the same DLL, can have their input signal phase shifted by a different degree amount but all must be referenced at one particular frequency. However, not all phase-shift combinations are supported.

The 7-bit DQS delay settings from the DLL vary with PVT to implement the phase-shift delay. For example, with a 0° shift, the DQS/CQ/CQn/QK# signal bypasses both the DLL and DQS logic blocks. The Quartus II software automatically sets the DQ input delay chains, so that the skew between the DQ and DQS/CQ/CQn/QK# pins at the DQ IOE registers is negligible if a 0° shift is implemented. You can feed the DQS delay settings to the DQS logic block and logic array.

The shifted DQS/CQ/CQn/QK# signal goes to the DQS bus to clock the IOE input registers of the DQ pins. The signal can also go into the logic array for resynchronization if you are not using IOE read FIFO for resynchronization.

For Arria V SoC devices, you can feed the hard processor system (HPS) DQS delay settings to the HPS DQS logic block only.

Figure 7-6: Simplified Diagram of the DQS Phase-Shift Circuitry (Arria V GX, GT, SX, and ST)

This figure shows a simple block diagram of the DLL in Arria V GZ devices. All features of the DQS phase-shift circuitry are accessible from the UniPHY megafunction in the Quartus II software.

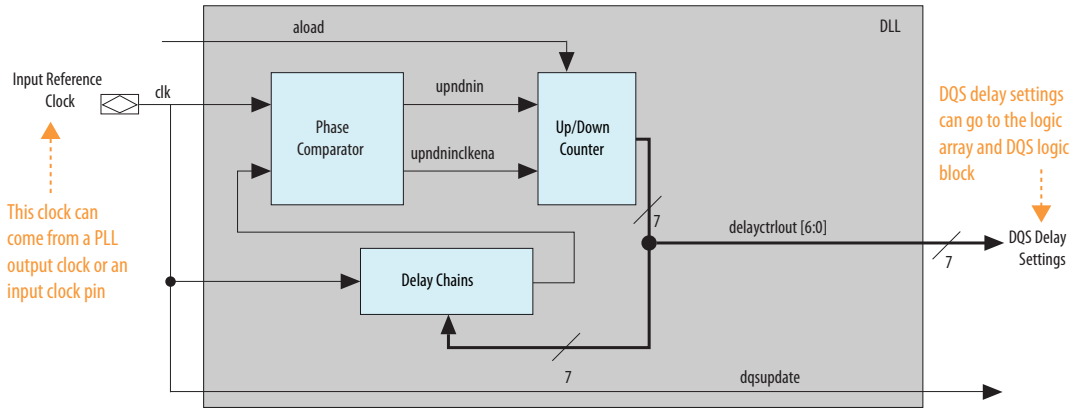

Figure 7-7: Simplified Diagram of the DQS Phase-Shift Circuitry (Arria V GZ)

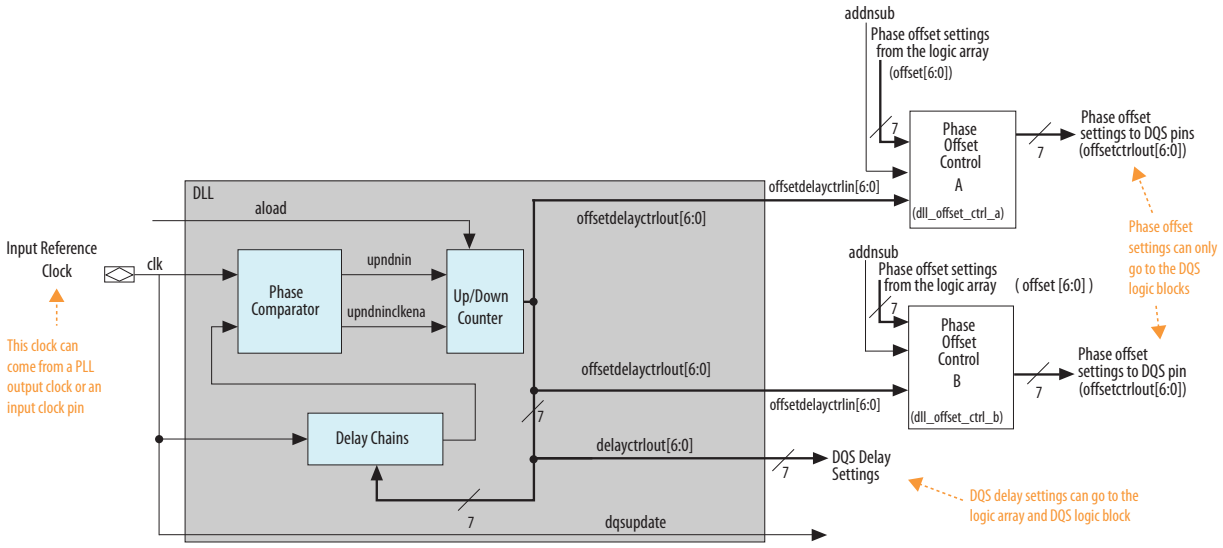
This figure shows a simple block diagram of the DLL in Arria V GZ devices. All features of the DQS phase-shift circuitry are accessible from the UniPHY megafunction in the Quartus II software.



The input reference clock goes into the DLL to a chain of up to eight delay elements. The phase comparator compares the signal coming out of the end of the delay chain block to the input reference clock. The phase comparator then issues the upndn signal to the Gray-code counter. This signal increments or decrements a 7-bit delay setting (DQS delay settings) that increases or decreases the delay through the delay element chain to bring the input reference clock and the signals coming out of the delay element chain in phase.

The DLL can be reset from either the logic array or a user I/O pin. Each time the DLL is reset, you must wait for 2,560 clock cycles for the DLL to lock before you can capture the data properly. The DLL phase comparator requires 2,560 clock cycles to lock and calculate the correct input clock period.

For the frequency range of each DLL frequency mode, refer to the device datasheet.

PHY Clock (PHYCLK) Networks

The PHYCLK network is a dedicated high-speed, low-skew balanced clock tree designed for a high-performance external memory interface.

The top and bottom sides of the Arria V devices have up to four PHYCLK networks. There are up to two PHYCLK networks on the left and right side I/O banks. Each PHYCLK network spans across one I/O bank and is driven by one of the PLLs located adjacent to the I/O bank.

The following figures show the PHYCLK networks available in the Arria V devices.

Figure 7-8: PHYCLK Networks in Arria V GX A1 and A3 Devices

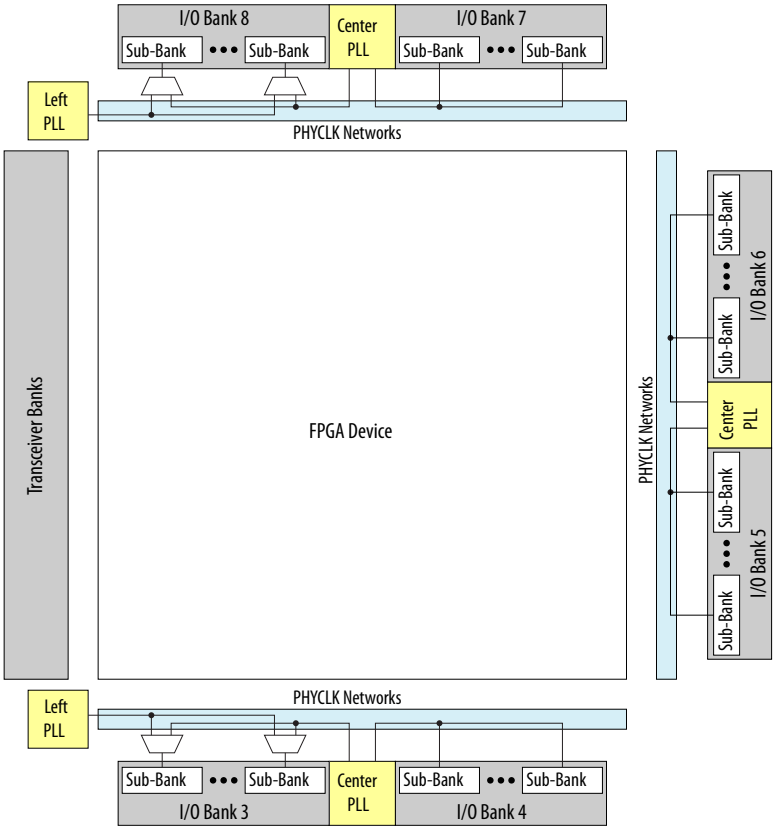

Figure 7-9: PHYCLK Networks in Arria V GX A5, A7, B1, B3, B5, and B7 Devices, and Arria V GZ E1, E3, E5, and E7 Devices

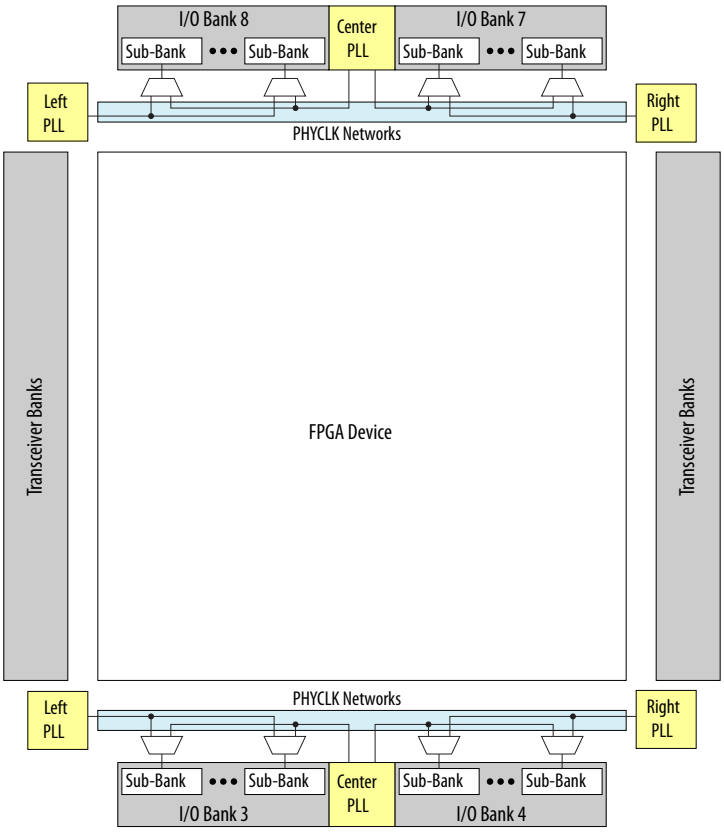

Figure 7-10: Arria V PHYCLK Networks in Arria V SX B3 and B5 Devices, and Arria V ST D3 and D5 Devices

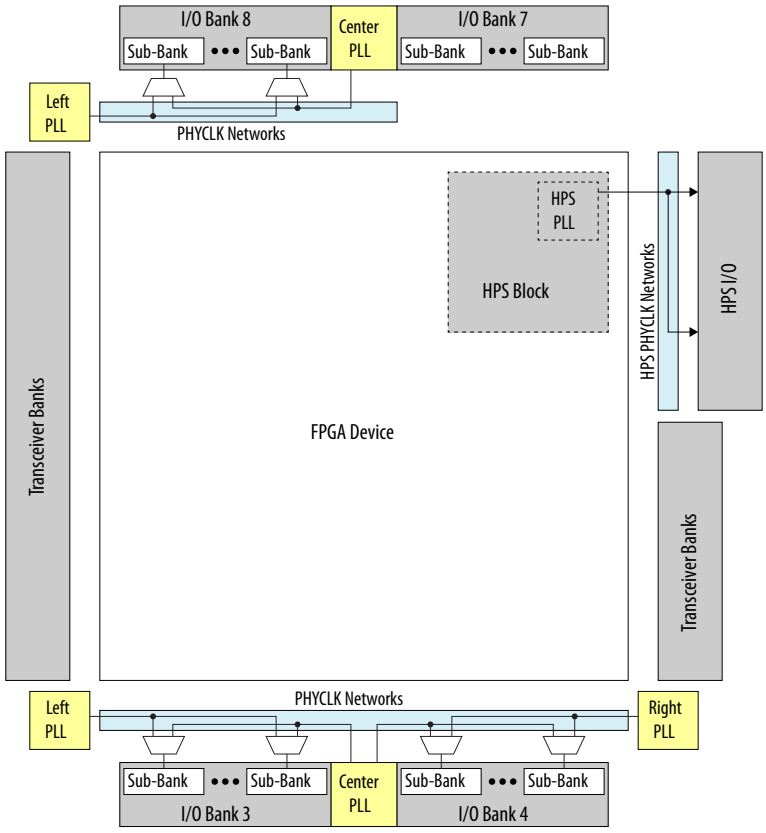

The PHYCLK network can be used to drive I/O sub-banks in each I/O bank. Each I/O sub-bank can be driven by only one PHYCLK network—all I/O pins in an I/O sub-bank are driven by the same PHYCLK network.

DQS Logic Block

Each DQS/CQ/CQn/QK# pin is connected to a separate DQS logic block, which consists of the update enable circuitry, DQS delay chains, and DQS postamble circuitry.

The following figure shows the DQS logic block.

Figure 7-11: DQS Logic Block in Arria V GX, GT, SX, and ST Devices

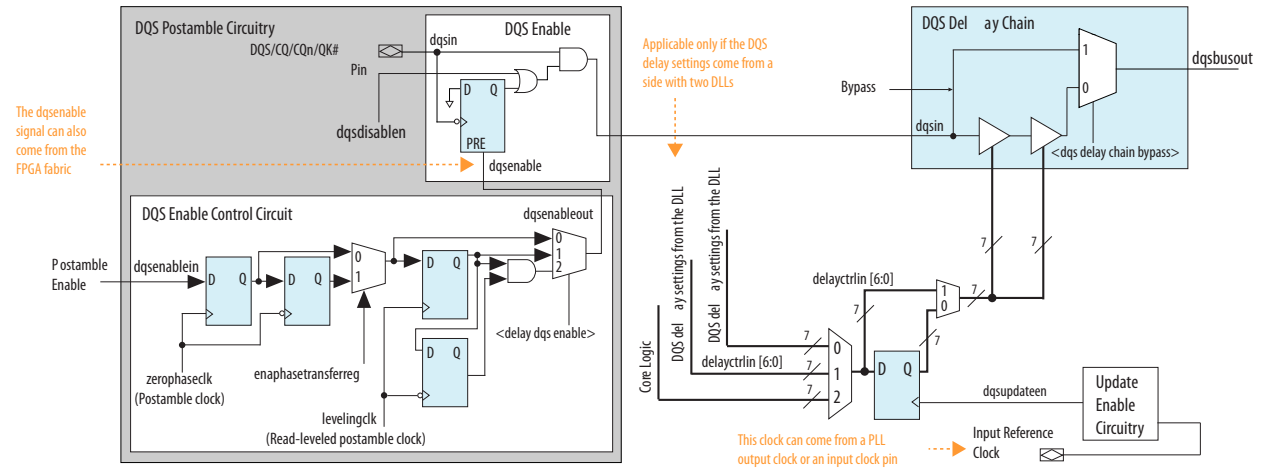

Figure 7-12: DQS Logic Block in Arria V GZ Devices

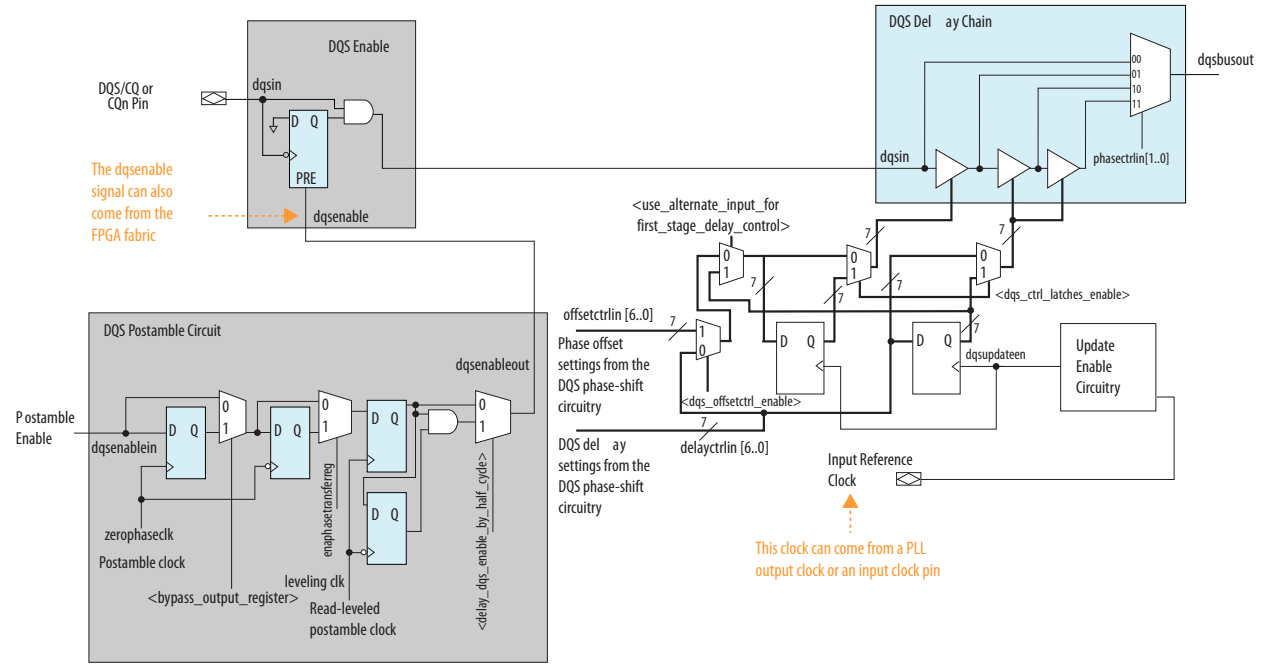


Update Enable Circuitry

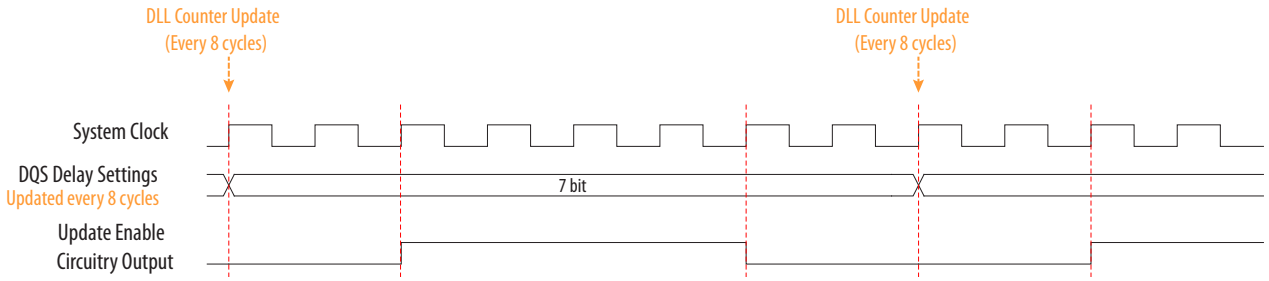
The update enable circuitry enables the registers to allow enough time for the DQS delay settings to travel from the DQS phase-shift circuitry or core logic to all the DQS logic blocks before the next change.

Both the DQS delay settings and the phase-offset settings pass through a register before going into the DQS delay chains. The registers are controlled by the update enable circuitry to allow enough time for any changes in the DQS delay setting bits to arrive at all the delay elements, which allows them to be adjusted at the same time.

The circuitry uses the input reference clock or a user clock from the core to generate the update enable output. The UniPHY intellectual property (IP) uses this circuit by default.

Figure 7-13: DQS Update Enable Waveform

This figure shows an example waveform of the update enable circuitry output.



DQS Delay Chain

DQS delay chains consist of a set of variable delay elements to allow the input DQS/CQ/CQn/QK# signals to be shifted by the amount specified by the DQS phase-shift circuitry or the logic array.

There are two delay elements in the DQS delay chain that have the same characteristics:

- Delay elements in the DQS logic block
- Delay elements in the DLL

The DQS/CQ/CQn/QK# pin is shifted by the DQS delay settings.

The number of delay chains required is transparent because the UniPHY IP automatically sets it when you choose the operating frequency.

In Arria V GX, GT, and GZ devices, if you do not use the DLL to control the DQS delay chains, you can input your own gray-coded 7 bit settings using the `delayctrlin[6..0]` signals available in the UniPHY IP.

In the Arria V SX and ST devices, the DQS delay chain is controlled by the DQS phase-shift circuitry only.

DQS Postamble Circuitry

There are preamble and postamble specifications for both read and write operations in DDR3 and DDR2 SDRAM. The DQS postamble circuitry ensures that data is not lost if there is noise on the DQS line during the end of a read operation that occurs while DQS is in a postamble state.

The Arria V devices contain dedicated postamble registers that you can control to ground the shifted DQS signal that is used to clock the DQ input registers at the end of a read operation. This function ensures that any glitches on the DQS input signal during the end of a read operation and occurring while DQS is in a postamble state do not affect the DQ IOE registers.

- For preamble state, the DQS is low, just after a high-impedance state.
- For postamble state, the DQS is low, just before it returns to a high-impedance state.

For external memory interfaces that use a bidirectional read strobe (DDR3 and DDR2 SDRAM), the DQS signal is low before going to or coming from a high-impedance state.

Half Data Rate Block

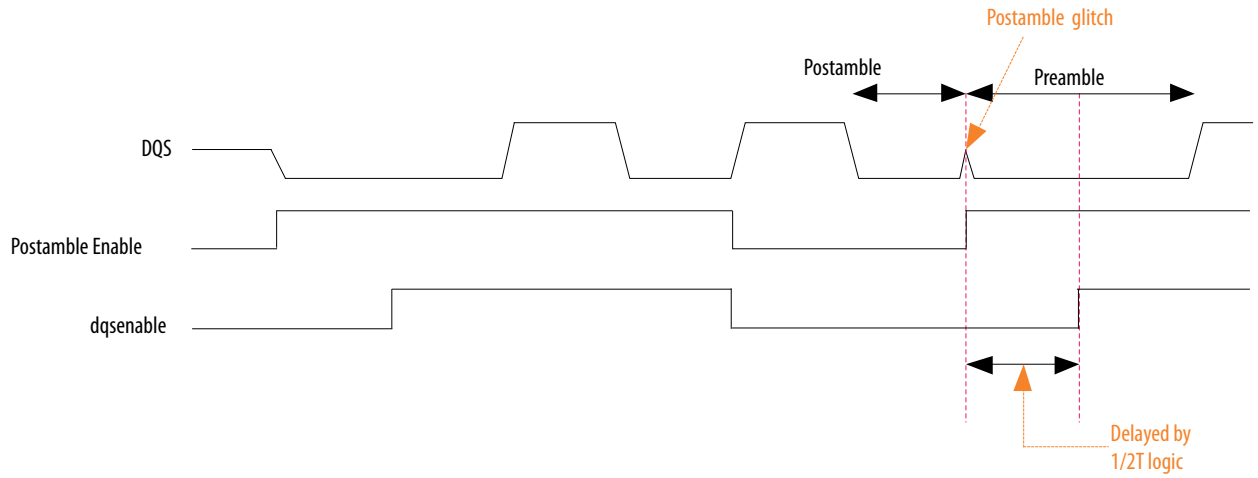
The Arria V devices contain a half data rate (HDR) block in the postamble enable circuitry.

The HDR block is clocked by the half-rate resynchronization clock, which is the output of the I/O clock divider circuit. There is an AND gate after the postamble register outputs to avoid postamble glitches from a previous read burst on a non-consecutive read burst. This scheme allows half-a-clock cycle latency for `dqsenable` assertion and zero latency for `dqsenable` deassertion.

Using the HDR block as the first stage capture register in the postamble enable circuitry block is optional. Altera recommends using these registers if the controller is running at half the frequency of the I/Os.

Figure 7-14: Avoiding Glitch on a Non-Consecutive Read Burst Waveform

This figure shows how to avoid postamble glitches using the HDR block.

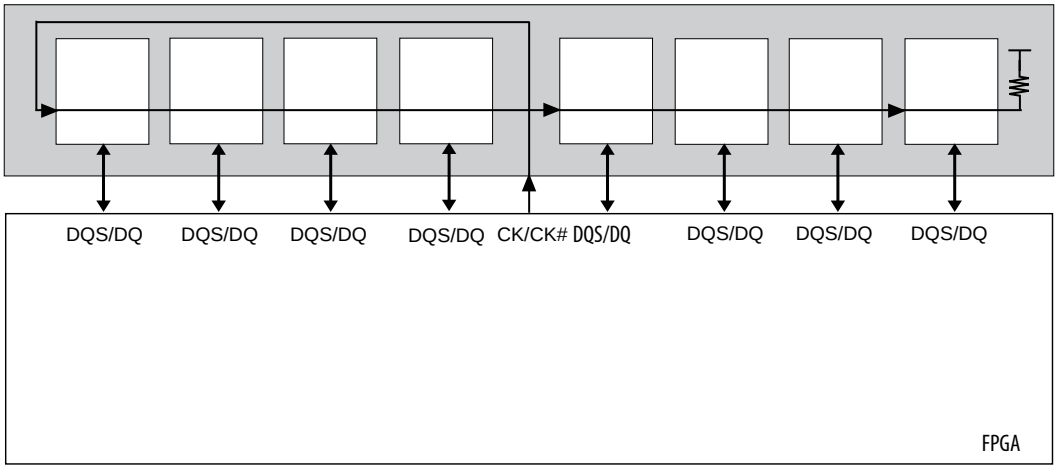


Leveling Circuitry for Arria V GZ Devices

DDR3 SDRAM unbuffered modules use a fly-by clock distribution topology for better signal integrity. This means that the CK/CK# signals arrive at each DDR3 SDRAM device in the module at different times. The difference in arrival time between the first DDR3 SDRAM device and the last device on the module can be as long as 1.6 ns.

The following figure shows the clock topology in DDR3 SDRAM unbuffered modules.

Figure 7-15: DDR3 SDRAM Unbuffered Module Clock Topology



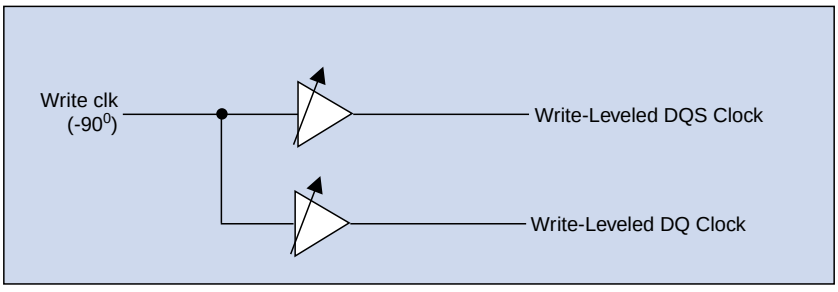
Because the data and read strobe signals are still point-to-point, take special care to ensure that the timing relationship between the CK/CK# and DQS signals (t_{DQSS}, t_{DSS}, and t_{DSH}) during a write is met at every device on the modules. In a similar way, read data coming back into the FPGA from the memory is also staggered.

The Arria V GZ devices have leveling circuitry to address these two situations. There is one leveling circuit per I/O sub-bank (for example, I/O sub-bank 1A, 1B, and 1C each has one leveling circuitry). These delay chains are PVT-compensated by the same DQS delay settings as the DLL and DQS delay chains.

The DLL uses eight delay chain taps, such that each delay chain tap generates a 45° delay. The generated clock phases are distributed to every DQS logic block that is available in the I/O sub-bank. The delay chain taps then feed a multiplexer controlled by the UniPHY megafunction to select which clock phases are to be used for that x4 or x 8 DQS group. Each group can use a different tap output from the read-leveling and write-leveling delay chains to compensate for the different CK/CK# delay going into each device on the module.

Figure 7-16: Write-Leveling Delay Chains and Multiplexers

There is one leveling delay chain per I/O sub-bank (for example, I/O sub-banks 1A, 1B, and 1C). You can only have one memory interface in each I/O sub-bank when you use the leveling delay chain.



The –90° write clock of the UniPHY IP feeds the write-leveling circuitry to produce the clock to generate the DQS and DQ signals. During initialization, the UniPHY IP picks the correct write-leveled clock for

the DQS and DQ clocks for each DQ/DQS group after sweeping all the available clocks in the write calibration process. The DQ clock output is –90° phase-shifted compared to the DQS clock output.

The UniPHY IP dynamically calibrates the alignment for read and write leveling during the initialization process.

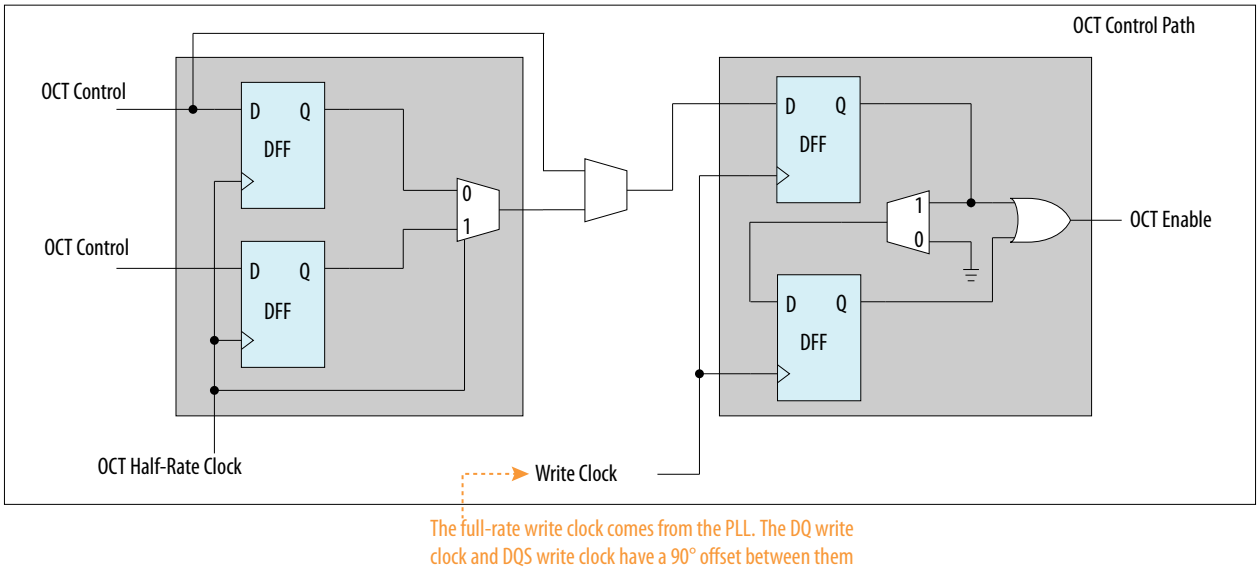
Dynamic OCT Control

The dynamic OCT control block includes all the registers that are required to dynamically turn the on-chip parallel termination (R_T OCT) on during a read and turn R_T OCT off during a write.

Figure 7-17: Dynamic OCT Control Block for Arria V Devices



Related Information

IOE Registers

The IOE registers are expanded to allow source-synchronous systems to have faster register-to-FIFO transfers and resynchronization. All top, bottom, and right IOEs have the same capability.

Input Registers

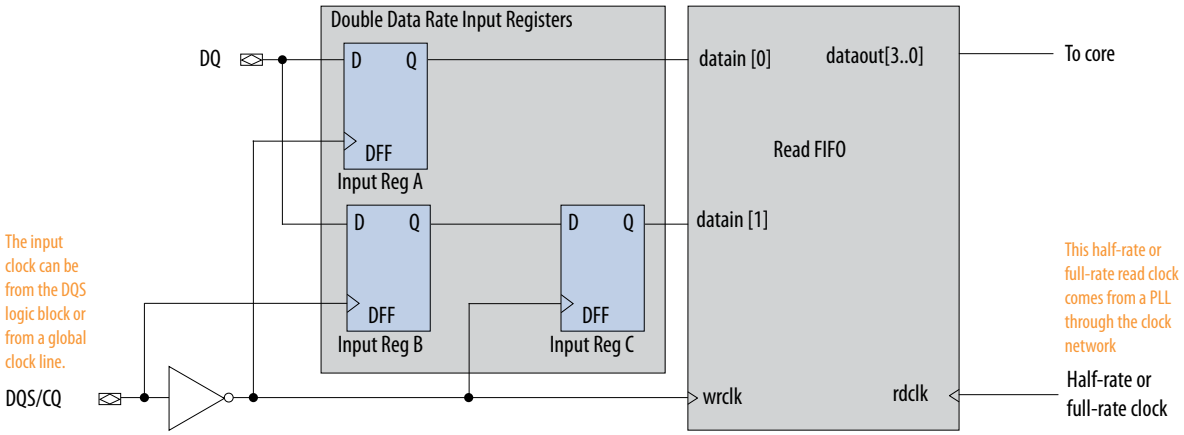
The input path consists of the DDR input registers and the read FIFO block. You can bypass each block of the input path.

There are three registers in the DDR input registers block. Registers A and B capture data on the positive and negative edges of the clock while register C aligns the captured data. Register C uses the same clock as Register A.

The read FIFO block resynchronizes the data to the system clock domain and lowers the data rate to half rate.

The following figure shows the registers available in the Arria V input path. For DDR3 and DDR2 SDRAM interfaces, the DQS and DQSn signals must be inverted. If you use Altera's memory interface IPs, the DQS and DQSn signals are automatically inverted.

Figure 7-18: IOE Input Registers for Arria V Devices



Output Registers

The Arria V output and output-enable path is divided into the HDR block, and output and output-enable registers. The device can bypass each block of the output and output-enable path.

The output path is designed to route combinatorial or registered single data rate (SDR) outputs and full-rate or half-rate DDR outputs from the FPGA core. Half-rate data is converted to full-rate with the HDR block, clocked by the half-rate clock from the PLL.

The output-enable path has a structure similar to the output path—ensuring that the output-enable path goes through the same delay and latency as the output path.

Figure 7-19: IOE Output and Output-Enable Path Registers for Arria V GX, GT, SX, and ST Devices

The following figure shows the registers available in the Arria V GX, GT, SX, and ST output and output-enable paths.

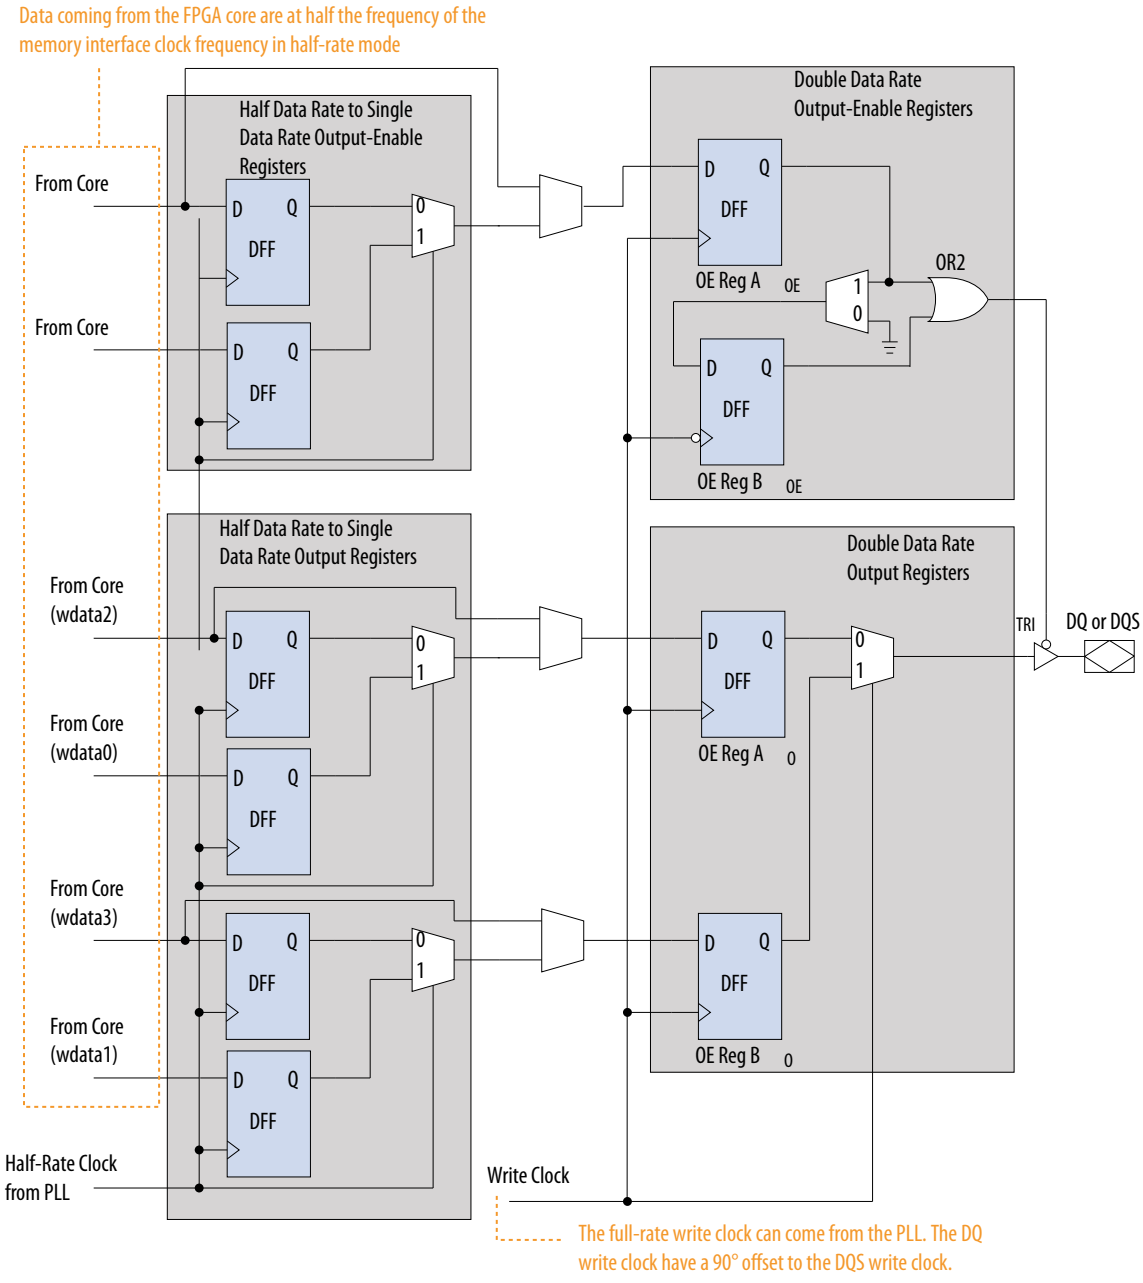


Figure 7-20: IOE Output and Output-Enable Path Registers for Arria V GZ Devices

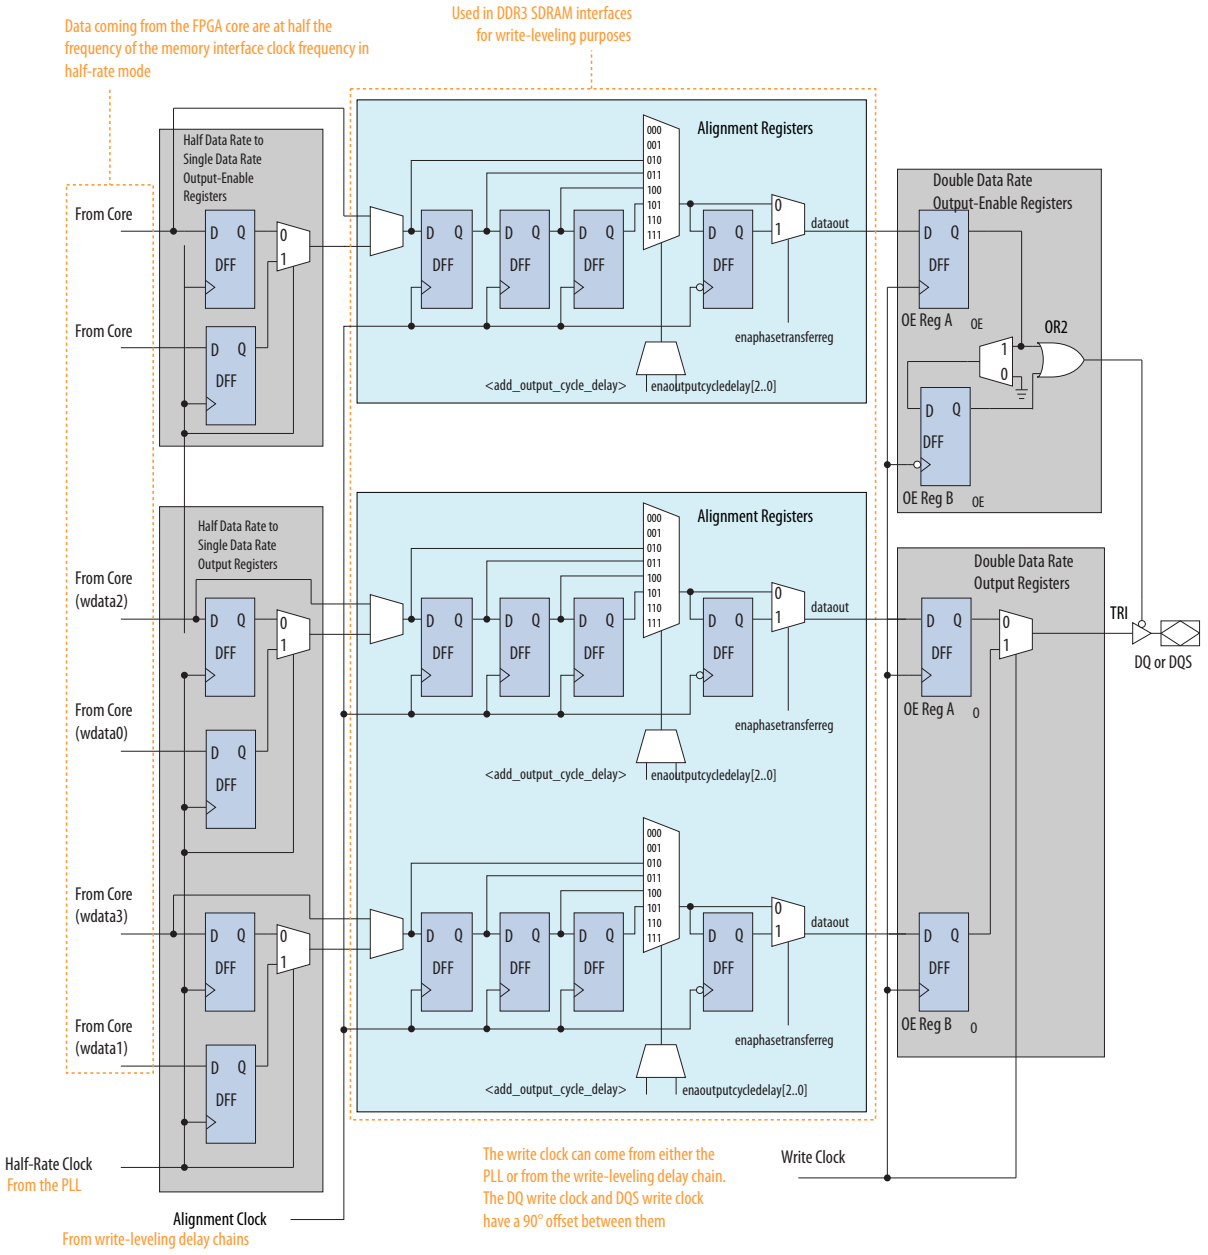
The following figure shows the registers available in the Arria V GZ output and output-enable paths. You can bypass each register block of the output and output-enable paths.



Delay Chains

The Arria V devices contain run-time adjustable delay chains in the I/O blocks and the DQS logic blocks. You can control the delay chain setting through the I/O or the DQS configuration block output.

Every I/O block contains a delay chain between the following elements:

- The output registers and output buffer
- The input buffer and input register
- The output enable and output buffer
- The R_T OCT enable-control register and output buffer

Figure 7-21: Delay Chains in an I/O Block in the Arria V GX, GT, SX, and ST Devices

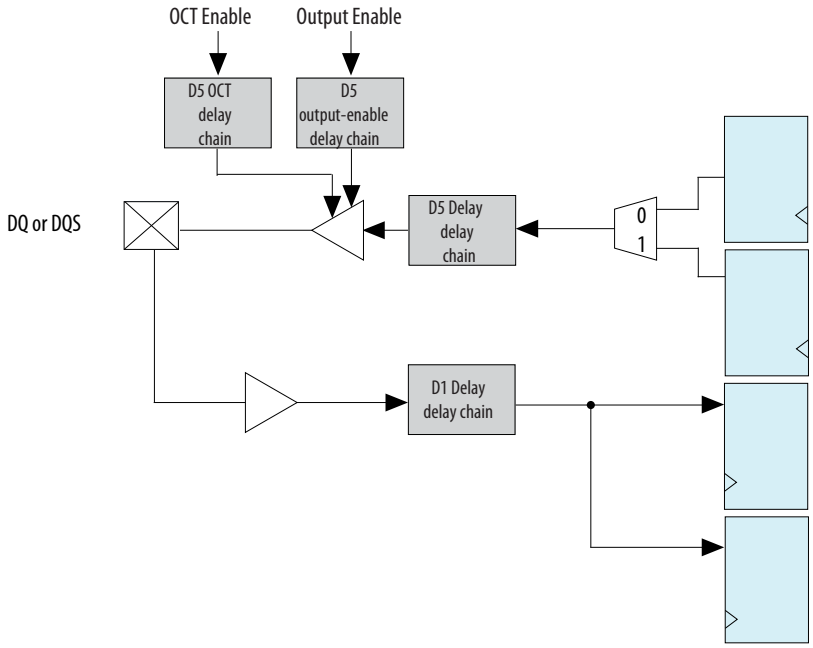


Figure 7-22: Delay Chains in an I/O Block in Arria V GZ Devices

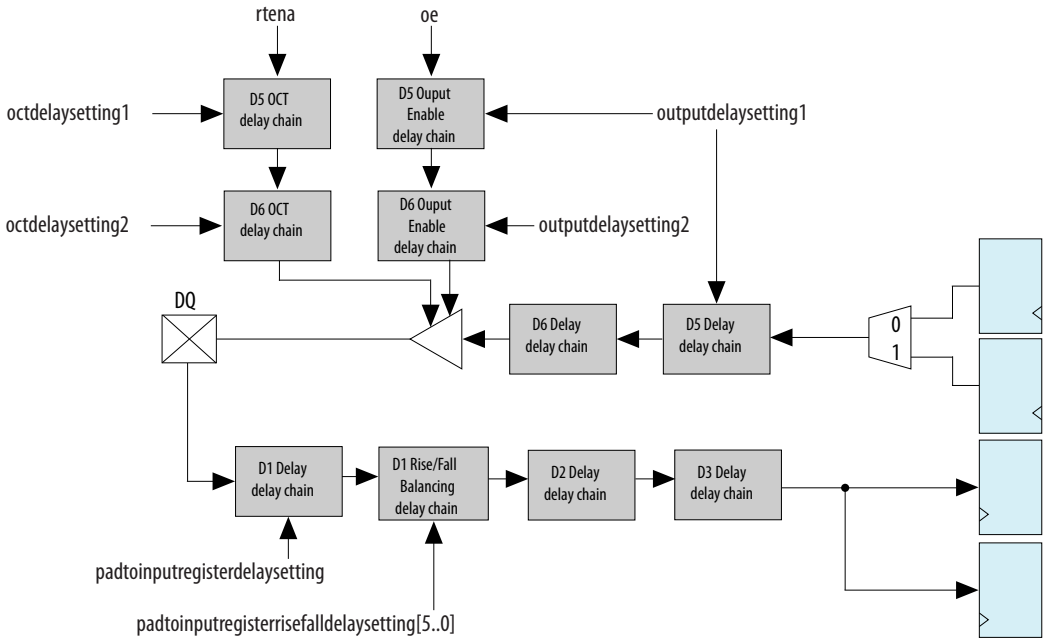

Each DQS logic block contains a delay chain after the `dqsbusout` output and another delay chain before the `dqsenable` input.

Figure 7-23: Delay Chains in the DQS Input Path

I/O and DQS Configuration Blocks

The I/O and DQS configuration blocks are shift registers that you can use to dynamically change the settings of various device configuration bits.

- The shift registers power-up low.
- Every I/O pin contains one I/O configuration register.
- Every DQS pin contains one DQS configuration block in addition to the I/O configuration register.

Figure 7-24: Configuration Block (I/O and DQS)

This figure shows the I/O configuration block and the DQS configuration block circuitry.

Hard Memory Controller

The Arria V GX, GT, SX, and ST devices feature dedicated hard memory controllers. You can use the hard memory controllers for DDR2 and DDR3 SDRAM interfaces. Compared to the memory controllers implemented using core logic, the hard memory controllers allow support for higher memory interface frequencies with shorter latency cycles.

The hard memory controllers use dedicated I/O pins as data, address, command, control, clock, and ground pins for the SDRAM interface. If you do not use the hard memory controllers, you can use these dedicated pins as regular I/O pins.

Note: There is no hard memory controller in the Arria V GZ devices.

Related Information

Features of the Hard Memory Controller

Table 7-17: Features of the Arria V Hard Memory Controller

Feature	Description
Memory Interface Data Width	• 8, 16, and 32 bit data • 16 bit data + 8 bit ECC • 32 bit data + 8bit ECC
Memory Density	The controller supports up to four gigabits density parts and two chip selects.
Memory Burst Length	• DDR3—Burst length of 8 and burst chop of 4 • DDR2—Burst lengths of 4 and 8
Command and Data Reordering	The controller increases efficiency through the support for out-of-order execution of DRAM commands—with address collision detection-and in-order return of results.
Starvation Control	A starvation counter ensures that all requests are served after a predefined time-out period. This function ensures that data with low priority access are not left behind when reordering data for efficiency.
User-Configurable Priority Support	When the controller detects a high priority request, it allows the request to bypass the current queuing request. This request is processed immediately and thus reduces latency.
Avalon®-MM Data Slave Local Interface	By default, the controller supports the Avalon Memory-Mapped protocol.
Bank Management	By default, the controller provides closed-page bank management on every access. The controller intelligently keeps a row open based on incoming traffic. This feature improves the efficiency of the controller especially for random traffic.
Streaming Reads and Writes	The controller can issue reads or writes continuously to sequential addresses every clock cycle if the bank is open. This function allows for very high efficiencies with large amounts of data.
Bank Interleaving	The controller can issue reads or writes continuously to 'random' addresses.
Predictive Bank Management	The controller can issue bank management commands early so that the correct row is open when the read or write occurs. This increases efficiency.
Multiport Interface	The interface allows you to connect up to six data masters to access the memory controller through the local interface. You can update the multiport scheduling configuration without interrupting traffic on a port.

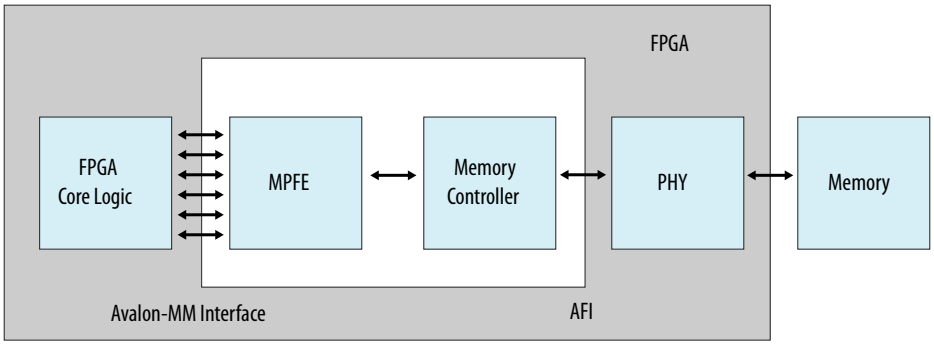
Feature	Description
Built-in Burst Adaptor	The controller can accept bursts of arbitrary sizes on its local interface and map these bursts to efficient memory commands.
Run-time Configuration of the Controller	This feature provides support for updates to the timing parameters without requiring reconfiguration of the FPGA, apart from the standard compile-time setting of the timing parameters.
On-Die Termination	The controller controls the on-die termination (ODT) in the memory, which improves signal integrity and simplifies your board design.
User-Controlled Refresh Timing	You can optionally control when refreshes occur—allowing the refreshes to avoid clashing of important reads or writes with the refresh lock-out time.
Low Power Modes	You can optionally request the controller to put the memory into the self-refresh or deep power-down modes.
Partial Array Self-Refresh	You can select the region of memory to refresh during self-refresh through the mode register to save power.
ECC	Standard Hamming single error correction, double error detection (SECDED) error correction code (ECC) support: • 32 bit data + 8 bit ECC • 16 bit data + 8 bit ECC
Additive Latency	With additive latency, the controller can issue a READ/WRITE command after the ACTIVATE command to the bank prior to t_{RCD} to increase the command efficiency. **Caution:** Efficiency degradation may occur when using the additive latency feature with the hard memory controller for DDR3 SDRAM interfaces at 533 MHz.
Write Acknowledgment	The controller supports write acknowledgment on the local interface.
User Control of Memory Controller Initialization	The controller supports initialization of the memory controller under the control of user logic—for example, through the software control in the user system if a processor is present.
Controller Bonding Support	You can bond two controllers to achieve wider data width for higher bandwidth applications.

Multi-Port Front End

The multi-port front end (MPFE) and its associated fabric interface provide up to six command ports, four read-data ports and four write-data ports, through which user logic can access the hard memory controller.

Figure 7-25: Simplified Diagram of the Arria V Hard Memory Interface

This figure shows a simplified diagram of the Arria V hard memory interface with the MPFE.



Bonding Support

Note: Bonding is supported only for hard memory controllers configured with one port. Do not use the bonding configuration when there is more than one port in each hard memory controller.

You can bond one port of any data width (64, 128, or 256 bits) from two hard memory controllers to support wider data widths.

If you bond two hard memory controllers, the data going out of the controllers to the user logic is synchronized. However, the data going out of the controllers to the memory is not synchronized.

The bonding controllers are not synchronized and remain independent with two separate address buses and two independent command buses. These buses are calibrated separately.

If you require ECC support for a bonded interface, you must implement the ECC logic external to the hard memory controllers.

Note: Only one bonding feature is available per package through the core fabric. A memory interface that uses the bonding feature has higher average latency.

Figure 7-26: Hard Memory Controllers Bonding Support in Arria V GX A1 and A3 Devices

This figure shows the bonding of two opposite hard memory controllers through the core fabric.

Document Revision History

Date	Version	Changes
January 2015	2015.01.23	• Updated hard memory controller widths for all devices. • Removed "Preliminary" notes.

Date	Version	Changes
June 2014	2014.06.30	• Added links to the Arria V Device Overview for more information about which device feature option supports the hard memory controllers. • Updated the hard memory controller widths for all devices where the widths are 64, 72, and 80 bits. The widths are now updated to "32 + 32", "40 + 32", and "40 + 40", respectively. The update is to clarify the maximum interface width per hard memory controller in the devices.
January 2014	2014.01.10	• Reduced the soft memory controller performance for DDR3 1.35 V in Arria V GX, GT, SX, and ST devices from 667 MHz to 600 MHz. • Removed support for DDR2 in the HPS hard memory controller. • Updated the figure that shows the delay chains in the Arria V GZ I/O block. • Added related information link to **ALTDQ_DQS2 Megafunction User Guide** for more information about using the delay chains. • Changed all "SoC FPGA" to "SoC". • Updated the figure that shows the DQS/CQ/CQn/QK# Pins and DLLs in Arria V GX A1 and A3 to add the DLL reference clock to the left side DLL. • Updated the topic about delay-locked loop (DLL) to specify that there is a maximum of five DLLs (instead of four). • Updated the topic about the PHYCLK networks to add information about using the PHYCLK network to drive the I/O sub-banks in each I/O bank. • Added links to Altera's **External Memory Spec Estimator** tool to the topics listing the external memory interface performance. • Updated topic about hard memory controller bonding support to specify that bonding is supported only for hard memory controllers configured with one port.
May 2013	2013.05.06	• Moved all links to the Related Information section of respective topics for easy reference. • Added link to the known document issues in the Knowledge Base. • Updated the topic about Arria V GZ leveling circuitry. • Removed the Arria V GZ phase offset control topic. • Added the I/O and DQS configuration blocks topic. • Updated the DQ/DQS groups for Arria V GX. • Added the DQ/DQS groups for Arria V GT C3 and C7. • Added the DLL reference clock input tables for all Arria V devices. • Added the FPGA hard memory controller widths for Arria V GX, GT, SX, and ST. • Added the HPS hard memory controller widths for Arria V SX and ST.

Date	Version	Changes
November 2012	2012.11.19	• Reorganized content and updated template. • Added information for Arria V GZ, including a topic on the leveling circuitry. • Added a list of supported external memory interface standards using the hard memory controller and soft memory controller. • Added performance information for external memory interfaces and the HPS external memory interfaces. • Separated the DQ/DQS groups tables into separate topics for each device variant for easy reference. • Moved the PHYCLK networks pin placement guideline to the **Planning Pin and FPGA Resources** chapter of the *External Memory Interface Handbook*. • Moved information from the "Design Considerations" section into relevant topics. • Removed the "DDR2 SDRAM Interface" and "DDR3 SDRAM DIMM" sections. Refer to the relevant sections in the **External Memory Interface Handbook** for the information. • Updated the diagram for DQS/CQ/CQn/QK# pins and DLLs in Arria V GX A1 and A3 devices to add DLLs on the right, top left, and bottom left, and update the DLL connections to the pins. • Updated the term "Multiport logic" to "multi-port front end" (MPFE).
June 2012	2.0	Updated for the Quartus II software v12.0 release: • Restructured chapter. • Updated “Design Considerations”, “DQS Postamble Circuitry”, and “IOE Registers”sections. • Added SoC devices information. • Added Figure 7–4, Figure 7–8, and Figure 7–20.
November 2011	1.1	• Updated Table 7–2. • Added “PHY Clock (PHYCLK) Networks” and “UniPHY IP” sections. • Restructured chapter.
May 2011	1.0	Initial release.

Configuration, Design Security, and Remote System Upgrades in Arria V Devices

Enhanced Configuration and Configuration via Protocol

Table 8-1: Configuration Modes and Features of Arria V Devices

Arria V devices support 1.8 V, 2.5 V, 3.0 V, and 3.3 V[20] programming voltages and several configuration modes.

Mode	Data Width	Max Clock Rate (MHz)	Max Data Rate (Mbps)	Decompression	Design Security	Partial Reconfiguration [21]	Remote System Update
AS through the EPCS and EPCQ serial configuration device	1 bit, 4 bits	100	—	Yes	Yes	—	Yes
PS through CPLD or external microcontroller	1 bit	125	125	Yes	Yes	—	—
FPP	8 bits	125	—	Yes	Yes	—	Parallel flash loader
	16 bits	125	—	Yes	Yes	Yes[22]	
	32 bits[23]	100	—	Yes	Yes	—	
CvP (PCIe)	x1, x2, x4, and x8 lanes	—	—	Yes	Yes	Yes	—
JTAG	1 bit	33	33	—	—	—	—
Configuration via HPS	16 bits	125	—	Yes	Yes	Yes [22]	Parallel flash loader
	32 bits	100	—	Yes	Yes	—	

Instead of using an external flash or ROM, you can configure the Arria V devices through PCIe using CvP. The CvP mode offers the fastest configuration rate and flexibility with the easy-to-use PCIe hard IP block interface. The Arria V CvP implementation conforms to the PCIe 100 ms power-up-to-active time requirement.

Note: Although Arria V GZ devices support PCIe Gen3, you can use only PCIe Gen1 and PCIe Gen2 for CvP configuration scheme.

Related Information

Configuration via Protocol (CvP) Implementation in Altera FPGAs User Guide
Provides more information about the CvP configuration scheme.

[20] Arria V GZ does not support 3.3 V.
[21] Partial reconfiguration is an advanced feature of the device family. If you are interested in using partial reconfiguration, contact Altera for support.
[22] Supported at a maximum clock rate of 62.5 MHz.
[23] Arria V GZ only

MSEL Pin Settings

To select a configuration scheme, hardwire the MSEL pins to V_{CCPGM} or GND without pull-up or pull-down resistors.

Note: Altera recommends connecting the MSEL pins directly to V_{CCPGM} or GND. Driving the MSEL pins from a microprocessor or another controlling device may not guarantee the V_{IL} or V_{IH} of the MSEL pins. The V_{IL} or V_{IH} of the MSEL pins must be maintained throughout configuration stages.

Table 8-2: MSEL Pin Settings for Each Configuration Scheme of Arria V Devices

Configuration Scheme	Compression Feature	Design Security Feature	V_{CCPGM} (V) (24)	Power-On Reset (POR) Delay	Valid MSEL[4..0]	Device Variant Support
FPP x8	Disabled	Disabled	1.8/2.5/3.0/3.3	Fast	10100	All
				Standard	11000	All
	Disabled	Enabled	1.8/2.5/3.0/3.3	Fast	10101	All
				Standard	11001	All
	Enabled	Enabled/Disabled	1.8/2.5/3.0/3.3	Fast	10110	All
				Standard	11010	All
FPP x16 (25)	Disabled	Disabled	1.8/2.5/3.0/3.3	Fast	00000	All
				Standard	00100	All
	Disabled	Enabled	1.8/2.5/3.0/3.3	Fast	00001	All
				Standard	00101	All
	Enabled	Enabled/Disabled	1.8/2.5/3.0/3.3	Fast	00010	All
				Standard	00110	All
FPP x32 (25)	Disabled	Disabled	1.8/2.5/3.0	Fast	01000	Arria V GZ
				Standard	01100	Arria V GZ
	Disabled	Enabled	1.8/2.5/3.0	Fast	01001	Arria V GZ
				Standard	01101	Arria V GZ
	Enabled	Enabled/Disabled	1.8/2.5/3.0	Fast	01010	Arria V GZ
				Standard	01110	Arria V GZ
PS	Enabled/Disabled	Enabled/Disabled	1.8/2.5/3.0/3.3	Fast	10000	All
				Standard	10001	All
AS (x1 and x4)	Enabled/Disabled	Enabled/Disabled	3.0/3.3	Fast	10010	All
				Standard	10011	All

(24) The Arria V GZ device does not support 3.3 V.
(25) For configuration with HPS in SoC FPGA devices, refer to the FPGA Manager for the related MSEL pin settings.

Configuration Scheme	Compression Feature	Design Security Feature	V_{CCPGM} (V) (24)	Power-On Reset (POR) Delay	Valid MSEL[4..0]	Device Variant Support
JTAG-based configuration	Disabled	Disabled	—	—	Use any valid MSEL pin settings above	All

Note: You must also select the configuration scheme in the **Configuration** page of the **Device and Pin Options** dialog box in the Quartus II software. Based on your selection, the option bit in the programming file is set accordingly.

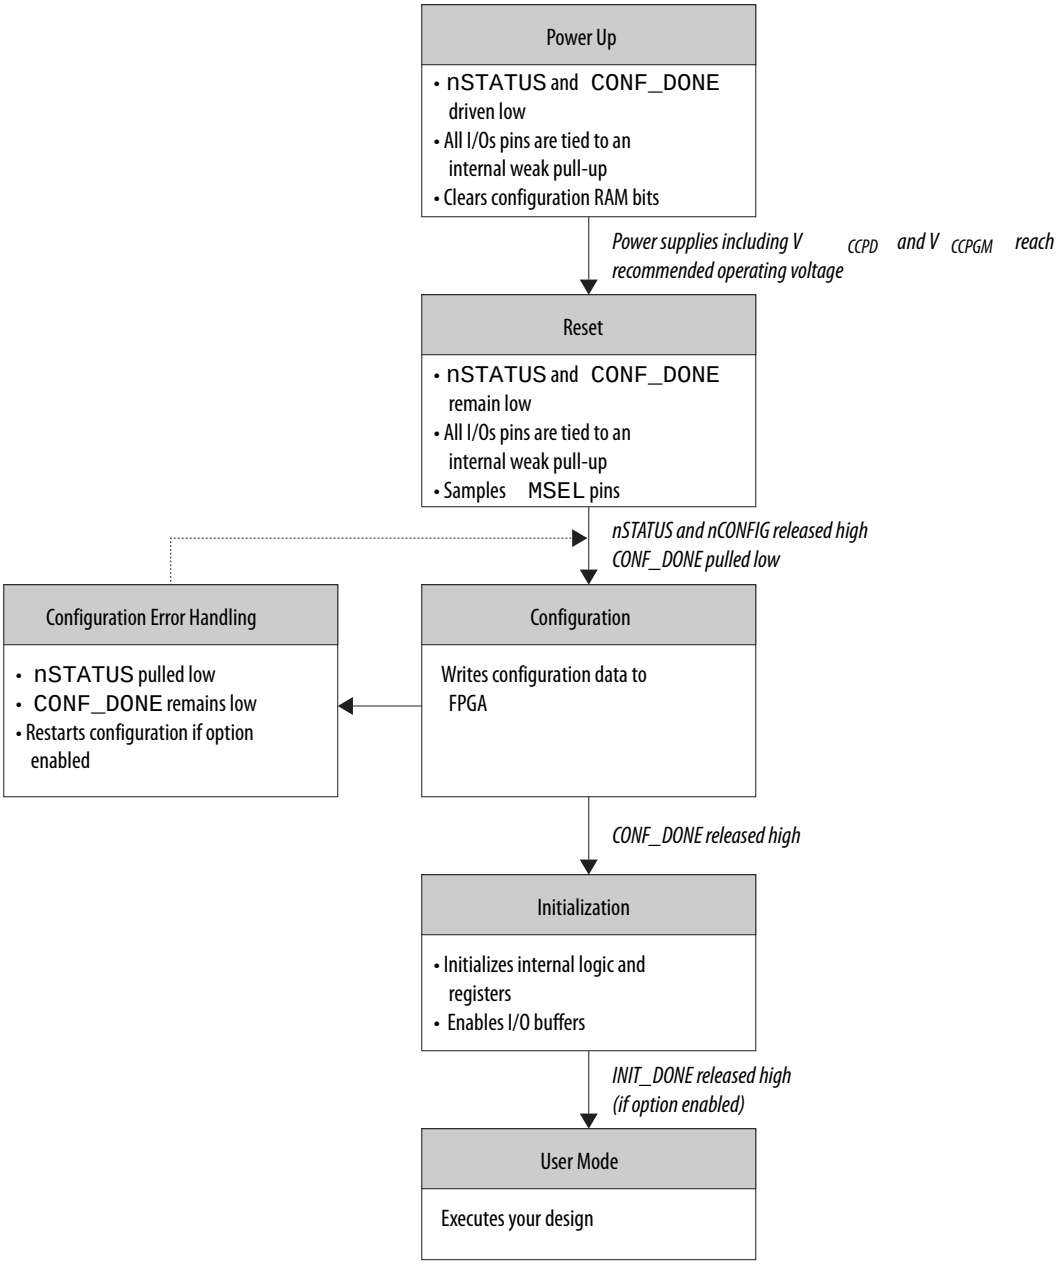
Configuration Sequence

Describes the configuration sequence and each configuration stage.

(24) The Arria V GZ device does not support 3.3 V.

Figure 8-1: Configuration Sequence for Arria V Devices



You can initiate reconfiguration by pulling the nCONFIG pin low to at least the minimum t_{CFG} low-pulse width except for configuration using the partial reconfiguration operation. When this pin is pulled low, the nSTATUS and CONF_DONE pins are pulled low and all I/O pins are tied to an internal weak pull-up.

Power Up

Power up all the power supplies that are monitored by the POR circuitry. All power supplies, including V_{CCPGM} and V_{CCPD}, must ramp up from 0 V to the recommended operating voltage level within the

ramp-up time specification. Otherwise, hold the nCONFIG pin low until all the power supplies reach the recommended voltage level.

V_{CCPGM} Pin

The configuration input buffers do not have to share power lines with the regular I/O buffers in Arria V devices.

The operating voltage for the configuration input pin is independent of the I/O banks power supply, V_{CCIO}, during configuration. Therefore, Arria V devices do not require configuration voltage constraints on V_{CCIO}.

V_{CCPD} Pin

Use the V_{CCPD} pin, a dedicated programming power supply, to power the I/O pre-drivers and JTAG I/O pins (TCK, TMS, TDI, and TDO).

The supported configuration voltages are 2.5, 3.0, and 3.3 V for all Arria V devices except for Arria V GZ devices. The supported configuration voltages for Arria V GZ devices are 2.5 and 3.0 V.

If V_{CCIO} of the bank is set to 2.5 V or lower, V_{CCPD} must be powered up at 2.5 V. If V_{CCIO} is set greater than 2.5 V, V_{CCPD} must be greater than V_{CCIO}. For example, when V_{CCIO} is set to 3.0 V, V_{CCPD} must be set at 3.0 V or above. When V_{CCIO} is set to 3.3 V, V_{CCPD} must be set at 3.3 V.

Reset

POR delay is the time frame between the time when all the power supplies monitored by the POR circuitry reach the recommended operating voltage and when nSTATUS is released high and the Arria V device is ready to begin configuration.

Set the POR delay using the MSEL pins.

The user I/O pins are tied to an internal weak pull-up until the device is configured.

  Provides more information about the POR delay specification.

Configuration

For more information about the DATA[] pins for each configuration scheme, refer to the appropriate configuration scheme.

Configuration Error Handling

To restart configuration automatically, turn on the **Auto-restart configuration after error** option in the **General** page of the **Device and Pin Options** dialog box in the Quartus II software.

If you do not turn on this option, you can monitor the nSTATUS pin to detect errors. To restart configuration, pull the nCONFIG pin low for at least the duration of t_{CFG}.

Related Information

Arria V Device Datasheet
Provides more information about t_{STATUS} and t_{CFG} timing parameters.

Initialization

The initialization clock source is from the internal oscillator, CLKUSR pin, or DCLK pin. By default, the internal oscillator is the clock source for initialization. If you use the internal oscillator, the Arria V device will be provided with enough clock cycles for proper initialization.

Note: If you use the optional CLKUSR pin as the initialization clock source and the nCONFIG pin is pulled low to restart configuration during device initialization, ensure that the CLKUSR or DCLK pin continues toggling until the nSTATUS pin goes low and then goes high again.

The CLKUSR pin provides you with the flexibility to synchronize initialization of multiple devices or to delay initialization. Supplying a clock on the CLKUSR pin during initialization does not affect configuration. After the CONF_DONE pin goes high, the CLKUSR or DCLK pin is enabled after the time specified by t_{CD2CU}. When this time period elapses, Arria V devices require a minimum number of clock cycles as specified by T_{init} to initialize properly and enter user mode as specified by the t_{CD2UMC} parameter.

Related Information

Arria V Device Datasheet
Provides more information about t_{CD2CU}, t_{init}, and t_{CD2UMC} timing parameters, and initialization clock source.

User Mode

You can enable the optional INIT_DONE pin to monitor the initialization stage. After the INIT_DONE pin is pulled high, initialization completes and your design starts executing. The user I/O pins will then function as specified by your design.

Device Configuration Pins

Configuration Pins Summary

The following table lists the Arria V configuration pins and their power supply.

Note: The TDI, TMS, TCK, and TDO pins are powered by V_{CCPD} of the bank in which the pin resides.

Note: The CLKUSR, DEV_OE, DEV_CLRn, DATA[15..5], and DATA[31..16] pins are powered by V_{CCPGM} during configuration and by V_{CCIO} of the bank in which the pin resides if you use it as a user I/O pin.

Table 8-3: Configuration Pin Summary for Arria V Devices

Configuration Pin	Configuration Scheme	Input/Output	User Mode	Powered By
TDI	JTAG	Input	—	V_{CCPD}
TMS	JTAG	Input	—	V_{CCPD}
TCK	JTAG	Input	—	V_{CCPD}
TDO	JTAG	Output	—	V_{CCPD}
CLKUSR	All schemes	Input	I/O	V_{CCPGM}/V_{CCIO} (26)
CRC_ERROR	Optional, all schemes	Output	I/O	Pull-up
CONF_DONE	All schemes	Bidirectional	—	V_{CCPGM}/Pull-up
DCLK	FPP and PS	Input	—	V_{CCPGM}
	AS	Output	—	V_{CCPGM}
DEV_OE	Optional, all schemes	Input	I/O	V_{CCPGM}/V_{CCIO} (26)
DEV_CLRn	Optional, all schemes	Input	I/O	V_{CCPGM}/V_{CCIO} (26)
INIT_DONE	Optional, all schemes	Output	I/O	Pull-up
MSEL[4..0]	All schemes	Input	—	V_{CCPGM}
nSTATUS	All schemes	Bidirectional	—	V_{CCPGM}/Pull-up
nCE	All schemes	Input	—	V_{CCPGM}
nCEO	All schemes	Output	I/O	Pull-up
nCONFIG	All schemes	Input	—	V_{CCPGM}

(26) This pin is powered by V_{CCPGM} during configuration and powered by V_{CCIO} of the bank in which the pin resides when you use this pin as a user I/O pin.

Configuration Pin	Configuration Scheme	Input/Output	User Mode	Powered By
nIO_PULLUP[27]	All schemes	Input	—	V_{CCPGM}
DATA[15..5]	FPP x8 and x16	Input	I/O	V_{CCPGM}/V_{CCIO} [26]
DATA[31..16] [27]	FPP x32	Input	I/O	V_{CCPGM}/V_{CCIO}[26]
DATA[4..0] [27]	FPP x8, x16, and x32	Input	I/O	V_{CCPGM}/V_{CCIO} [26]
nCSO/DATA4 [28]	AS	Output	—	V_{CCPGM}
	FPP	Input	—	V_{CCPGM}
AS_DATA[3..1]/ DATA[3..1] [28]	AS	Bidirectional	—	V_{CCPGM}
	FPP	Input	—	V_{CCPGM}
AS_DATA0/DATA0/ASDO [28]	AS	Bidirectional	—	V_{CCPGM}
	FPP and PS	Input	—	V_{CCPGM}
AS_DATA0/ASDO[27]	AS	Bidirectional	—	V_{CCPGM}
AS_DATA[3..1][27]	AS	Bidirectional	—	V_{CCPGM}
PR_REQUEST	Partial Reconfiguration	Input	I/O	V_{CCPGM}/V_{CCIO} [26]
PR_READY	Partial Reconfiguration	Output	I/O	V_{CCPGM}/V_{CCIO} [26]
PR_ERROR	Partial Reconfiguration	Output	I/O	V_{CCPGM}/V_{CCIO} [26]
PR_DONE	Partial Reconfiguration	Output	I/O	V_{CCPGM}/V_{CCIO} [26]

Fast Passive Parallel Configuration

The FPP configuration scheme uses an external host, such as a microprocessor, MAX® II device, or MAX V device. This scheme is the fastest method to configure Arria V devices. The FPP configuration scheme supports 8- and 16-bits data width.

You can use an external host to control the transfer of configuration data from an external storage such as flash memory to the FPGA. The design that controls the configuration process resides in the external host. You can store the configuration data in Raw Binary File (**.rbf**), Hexadecimal (Intel-Format) File (**.hex**), or Tabular Text File (**.ttf**) formats.

You can use the PFL megafunction with a MAX II or MAX V device to read configuration data from the flash memory device and configure the Arria V device.

Note: Two DCLK falling edges are required after the CONF_DONE pin goes high to begin the initialization of the device for both uncompressed and compressed configuration data in an FPP configuration.

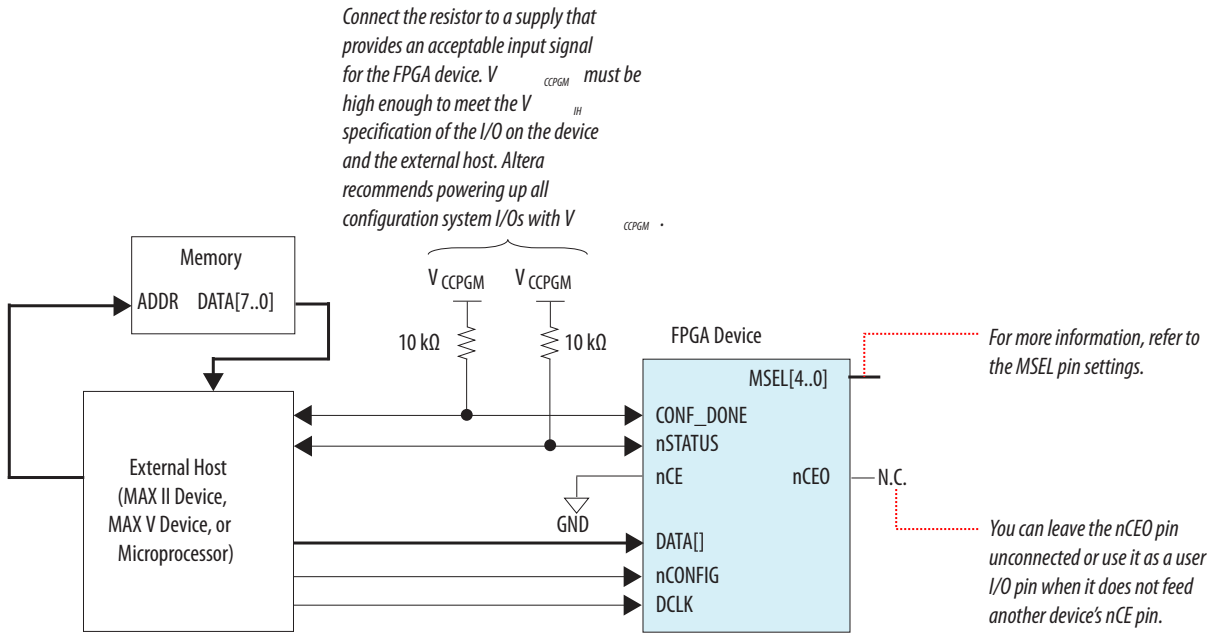
Related Information

- **Parallel Flash Loader Megafunction User Guide**
- **Arria V Device Datasheet**
  Provides more information about the FPP configuration timing.

Fast Passive Parallel Single-Device Configuration

To configure an Arria V device, connect the device to an external host as shown in the following figure.

Figure 8-2: Single Device FPP Configuration Using an External Host



Fast Passive Parallel Multi-Device Configuration

You can configure multiple Arria V devices that are connected in a chain.

Pin Connections and Guidelines

Observe the following pin connections and guidelines for this configuration setup:

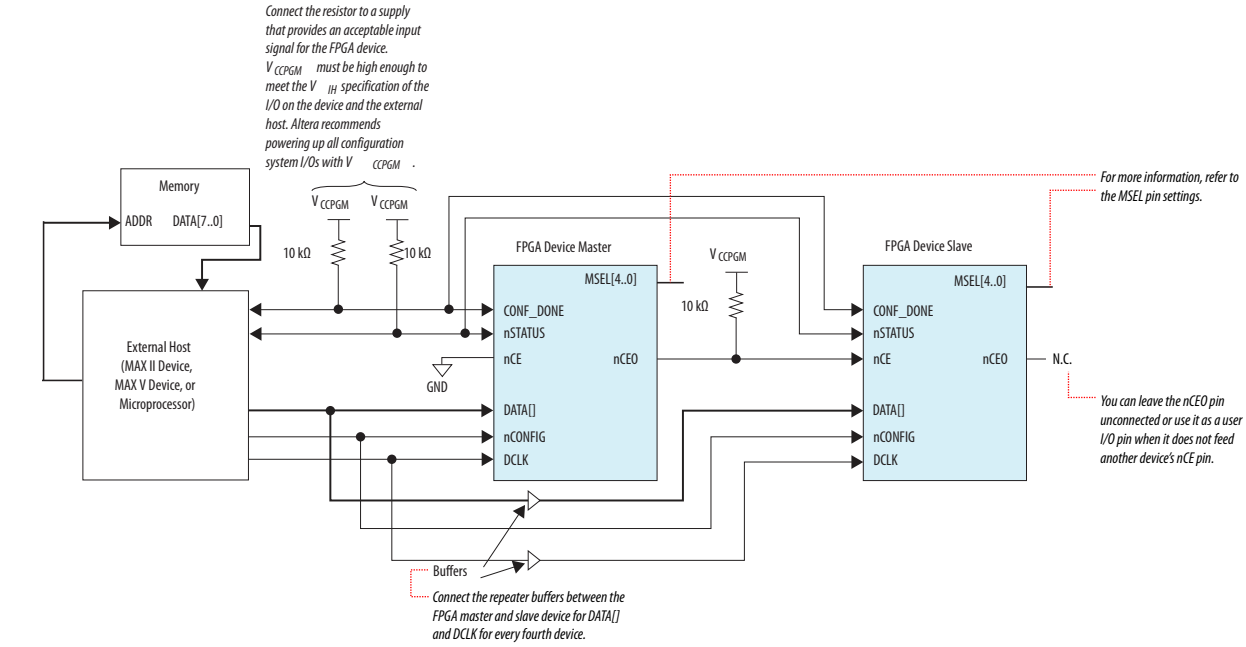
- Tie the following pins of all devices in the chain together:
  - nCONFIG
  - nSTATUS
  - DCLK
  - DATA[]
  - CONF_DONE

  By tying the CONF_DONE and nSTATUS pins together, the devices initialize and enter user mode at the same time. If any device in the chain detects an error, configuration stops for the entire chain and you must reconfigure all the devices. For example, if the first device in the chain flags an error on the nSTATUS pin, it resets the chain by pulling its nSTATUS pin low.
- Ensure that DCLK and DATA[] are buffered for every fourth device to prevent signal integrity and clock skew problems.
- All devices in the chain must use the same data width.
- If you are configuring the devices in the chain using the same configuration data, the devices must be of the same package and density.

Using Multiple Configuration Data

To configure multiple Arria V devices in a chain using multiple configuration data, connect the devices to an external host as shown in the following figure.

Figure 8-3: Multiple Device FPP Configuration Using an External Host When Both Devices Receive a Different Set of Configuration Data

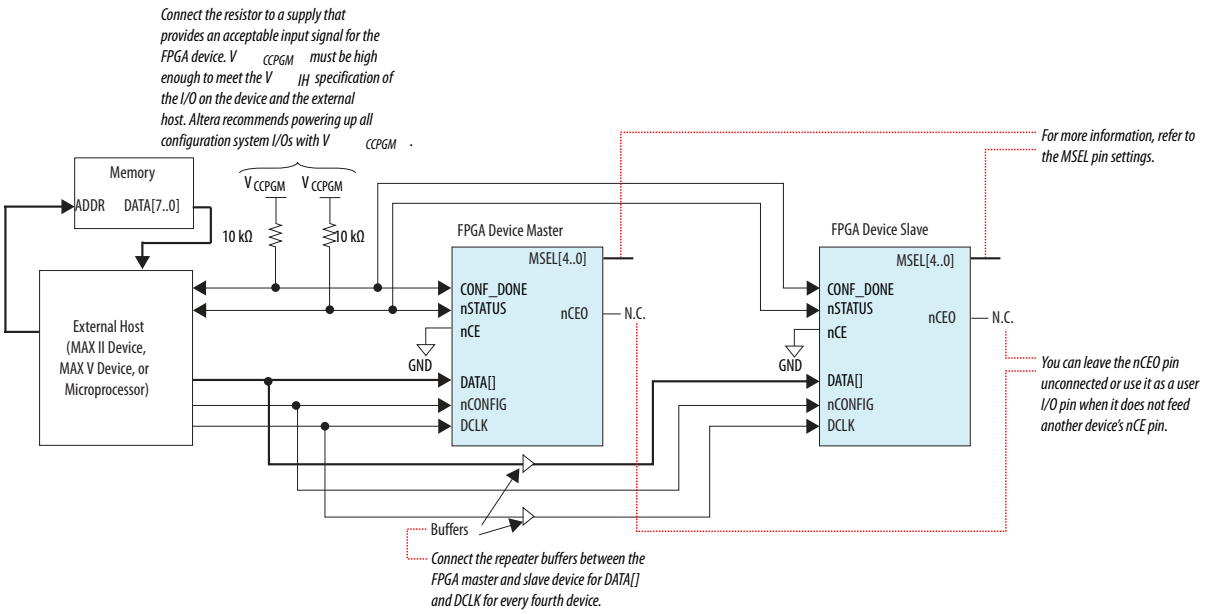


When a device completes configuration, its nCEO pin is released low to activate the nCE pin of the next device in the chain. Configuration automatically begins for the second device in one clock cycle.

Using One Configuration Data

To configure multiple Arria V devices in a chain using one configuration data, connect the devices to an external host as shown in the following figure.

Figure 8-4: Multiple Device FPP Configuration Using an External Host When Both Devices Receive the Same Data



The nCE pins of the device in the chain are connected to GND, allowing configuration for these devices to begin and end at the same time.

Transmitting Configuration Data

This section describes how to transmit configuration data when you are using **.rbf** file for FPP x8, x16, and x32 configuration modes. The configuration data in the **.rbf** file is little endian.

For example, if the **.rbf** file contains the byte sequence 02 1B EE 01, refer to the following tables for details on how this data is transmitted in the FPP x8, x16, and x32 configuration modes.

Table 8-5: Transmitting Configuration Data for FPP x8 Configuration Mode

In FPP x8 configuration mode, the LSB of a byte is BIT0, and the MSB is BIT7.

BYTE0 = 02	BYTE1 = 1B	BYTE2 = EE	BYTE3 = 01
D[7..0]	D[7..0]	D[7..0]	D[7..0]
0000 0010	0001 1011	1110 1110	0000 0001

Table 8-6: Transmitting Configuration Data for FPP x16 Configuration Mode

In FPP x16 configuration mode, the first byte in the file is the LSB of the configuration word, and the second byte in the file is the MSB of the configuration word.

WORD0 = 1B02		WORD1 = 01EE	
LSB: BYTE0 = 02	MSB: BYTE1 = 1B	LSB: BYTE2 = EE	MSB: BYTE3 = 01
D[7..0]	D[15..8]	D[7..0]	D[15..8]
0000 0010	0001 1011	1110 1110	0000 0001

Table 8-7: Transmitting Configuration Data for FPP x32 Configuration Mode

In FPP x32 configuration mode, the first byte in the file is the LSB of the configuration double word, and the fourth byte is the MSB.

Double Word = 01EE1B02			
LSB: BYTE0 = 02	BYTE1 = 1B	BYTE2 = EE	MSB: BYTE3 = 01
D[7..0]	D[15..8]	D[23..16]	D[31..24]
0000 0010	0001 1011	1110 1110	0000 0001

Ensure that you do not swap the the upper bits or bytes with the lower bits or bytes when performing the FPP configuration. Sending incorrect configuration data during the configuration process may cause unexpected behavior on the CONF_DONE signal.

Active Serial Configuration

The AS configuration scheme supports AS x1 (1-bit data width) and AS x4 (4-bit data width) modes. The AS x4 mode provides four times faster configuration time than the AS x1 mode. In the AS configuration scheme, the Arria V device controls the configuration interface.

Related Information

Arria V Device Datasheet
Provides more information about the AS configuration timing.

DATA Clock (DCLK)

Arria V devices generate the serial clock, DCLK, that provides timing to the serial interface. In the AS configuration scheme, Arria V devices drive control signals on the falling edge of DCLK and latch the configuration data on the following falling edge of this clock pin.

The maximum DCLK frequency supported by the AS configuration scheme is 100 MHz except for the AS multi-device configuration scheme. You can source DCLK using CLKUSR or the internal oscillator. If you use the internal oscillator, you can choose a 12.5, 25, 50, or 100 MHz clock under the **Device and Pin Options** dialog box, in the **Configuration** page of the Quartus II software.

After power-up, DCLK is driven by a 12.5 MHz internal oscillator by default. The Arria V device determines the clock source and frequency to use by reading the option bit in the programming file.

Related Information

Arria V Device Datasheet

Provides more information about the DCLK frequency specification in the AS configuration scheme.

Active Serial Single-Device Configuration

To configure an Arria V device, connect the device to a serial configuration (EPCS) device or quad-serial configuration (EPCQ) device, as shown in the following figures.

Figure 8-5: Single Device AS x1 Mode Configuration

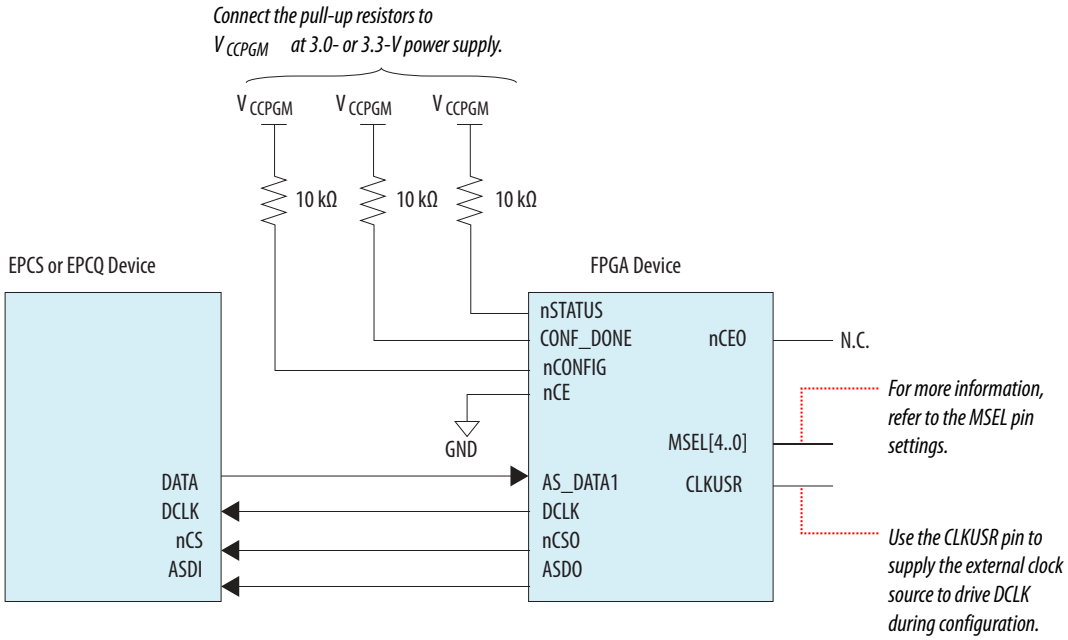


Figure 8-6: Single Device AS x4 Mode Configuration

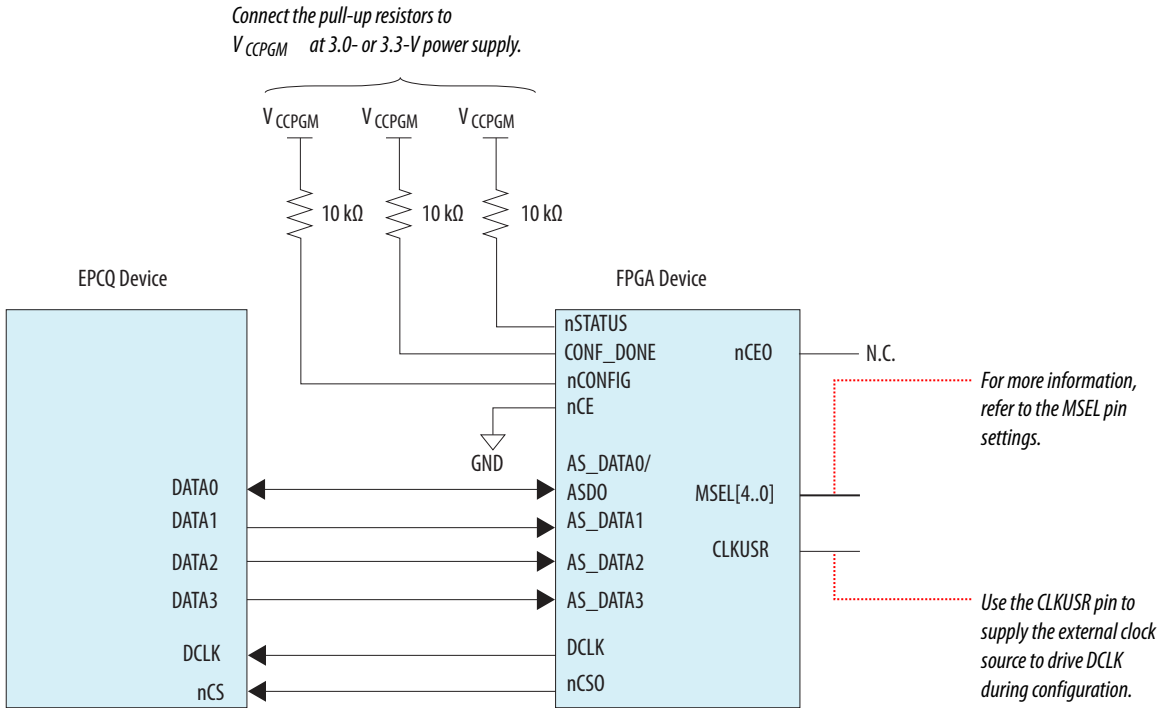


Active Serial Multi-Device Configuration

You can configure multiple Arria V devices that are connected to a chain. Only AS x1 mode supports multi-device configuration.

The first device in the chain is the configuration master. Subsequent devices in the chain are configuration slaves.

Pin Connections and Guidelines

Observe the following pin connections and guidelines for this configuration setup:

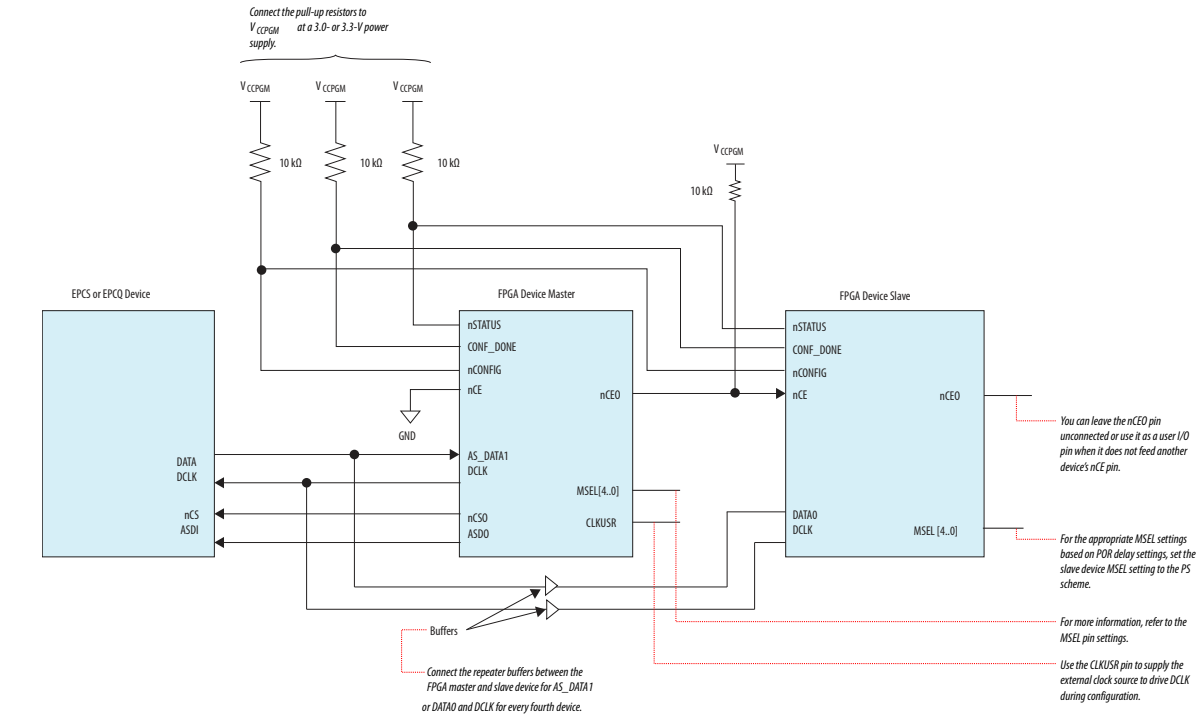
- Hardwire the MSEL pins of the first device in the chain to select the AS configuration scheme. For subsequent devices in the chain, hardwire their MSEL pins to select the PS configuration scheme. Any other Altera devices that support the PS configuration can also be part of the chain as a configuration slave.
- Tie the following pins of all devices in the chain together:
  - nCONFIG
  - nSTATUS
  - DCLK
  - DATA[]
  - CONF_DONE

  By tying the CONF_DONE, nSTATUS, and nCONFIG pins together, the devices initialize and enter user mode at the same time. If any device in the chain detects an error, configuration stops for the entire chain and you must reconfigure all the devices. For example, if the first device in the chain flags an error on the nSTATUS pin, it resets the chain by pulling its nSTATUS pin low.
- Ensure that DCLK and DATA[] are buffered every fourth device to prevent signal integrity and clock skew problems.

Using Multiple Configuration Data

To configure multiple Arria V devices in a chain using multiple configuration data, connect the devices to an EPCS or EPCQ device, as shown in the following figure.

Figure 8-7: Multiple Device AS Configuration When Both Devices in the Chain Receive Different Sets of Configuration Data



When a device completes configuration, its nCEO pin is released low to activate the nCE pin of the next device in the chain. Configuration automatically begins for the second device in one clock cycle.

Estimating the Active Serial Configuration Time

The AS configuration time is mostly the time it takes to transfer the configuration data from an EPCS or EPCQ device to the Arria V device.

Use the following equations to estimate the configuration time:

- AS x1 mode

  .rbf Size x (minimum DCLK period / 1 bit per DCLK cycle) = estimated minimum configuration time.
- AS x4 mode

  .rbf Size x (minimum DCLK period / 4 bits per DCLK cycle) = estimated minimum configuration time.

Compressing the configuration data reduces the configuration time. The amount of reduction varies depending on your design.

Using EPCS and EPCQ Devices

EPCS devices support AS x1 mode and EPCQ devices support AS x1 and AS x4 modes.

Related Information

- **Serial Configuration (EPCS) Devices Datasheet**
- **Quad-Serial Configuration (EPCQ) Devices Datasheet**

Controlling EPCS and EPCQ Devices

During configuration, Arria V devices enable the EPCS or EPCQ device by driving its nCSO output pin low, which connects to the chip select (nCS) pin of the EPCS or EPCQ device. Arria V devices use the DCLK and ASDO pins to send operation commands and read address signals to the EPCS or EPCQ device. The EPCS or EPCQ device provides data on its serial data output (DATA[]) pin, which connects to the AS_DATA[] input of the Arria V devices.

Note: If you wish to gain control of the EPCS pins, hold the nCONFIG pin low and pull the nCE pin high. This causes the device to reset and tri-state the AS configuration pins.

Trace Length and Loading

The maximum trace length and loading apply to both single- and multi-device AS configuration setups as listed in the following table. The trace length is the length from the Arria V device to the EPCS or EPCQ device.

Table 8-8: Maximum Trace Length and Loading for AS x1 and x4 Configurations for Arria V Devices

Arria V Device AS Pins	Maximum Board Trace Length (Inches)		Maximum Board Load (pF)
	12.5/ 25/ 50 MHz	100 MHz	
DCLK	10	6	5
DATA[3..0]	10	6	10

Arria V Device AS Pins	Maximum Board Trace Length (Inches)		Maximum Board Load (pF)
	12.5/ 25/ 50 MHz	100 MHz	
nCSO	10	6	10

Programming EPCS and EPCQ Devices

You can program EPCS and EPCQ devices in-system using a USB-Blaster™, EthernetBlaster, EthernetBlaster II, or ByteBlaster™ II download cable. Alternatively, you can program the EPCS or EPCQ using a microprocessor with the SRunner software driver.

In-system programming (ISP) offers you the option to program the EPCS or EPCQ either using an AS programming interface or a JTAG interface. Using the AS programming interface, the configuration data is programmed into the EPCS by the Quartus II software or any supported third-party software. Using the JTAG interface, an Altera IP called the serial flash loader (SFL) must be downloaded into the Arria V device to form a bridge between the JTAG interface and the EPCS or EPCQ. This allows the EPCS or EPCQ to be programmed directly using the JTAG interface.

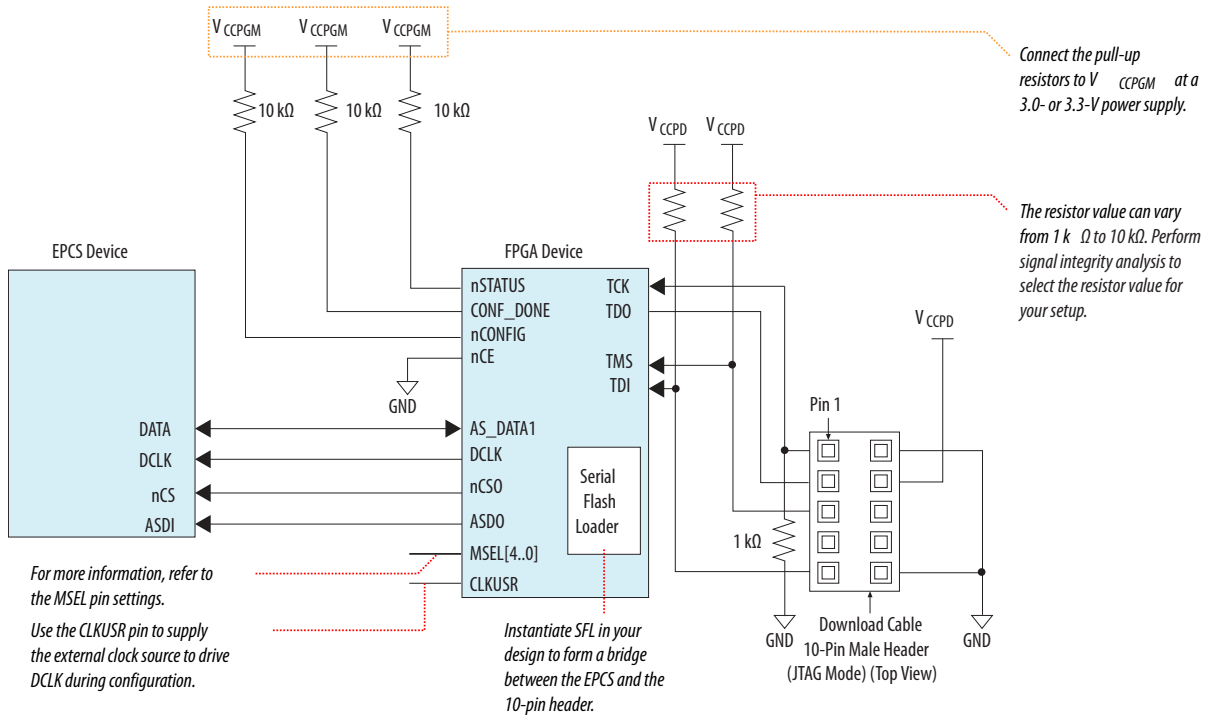
Programming EPCS Using the JTAG Interface

To program an EPCS device using the JTAG interface, connect the device as shown in the following figure.

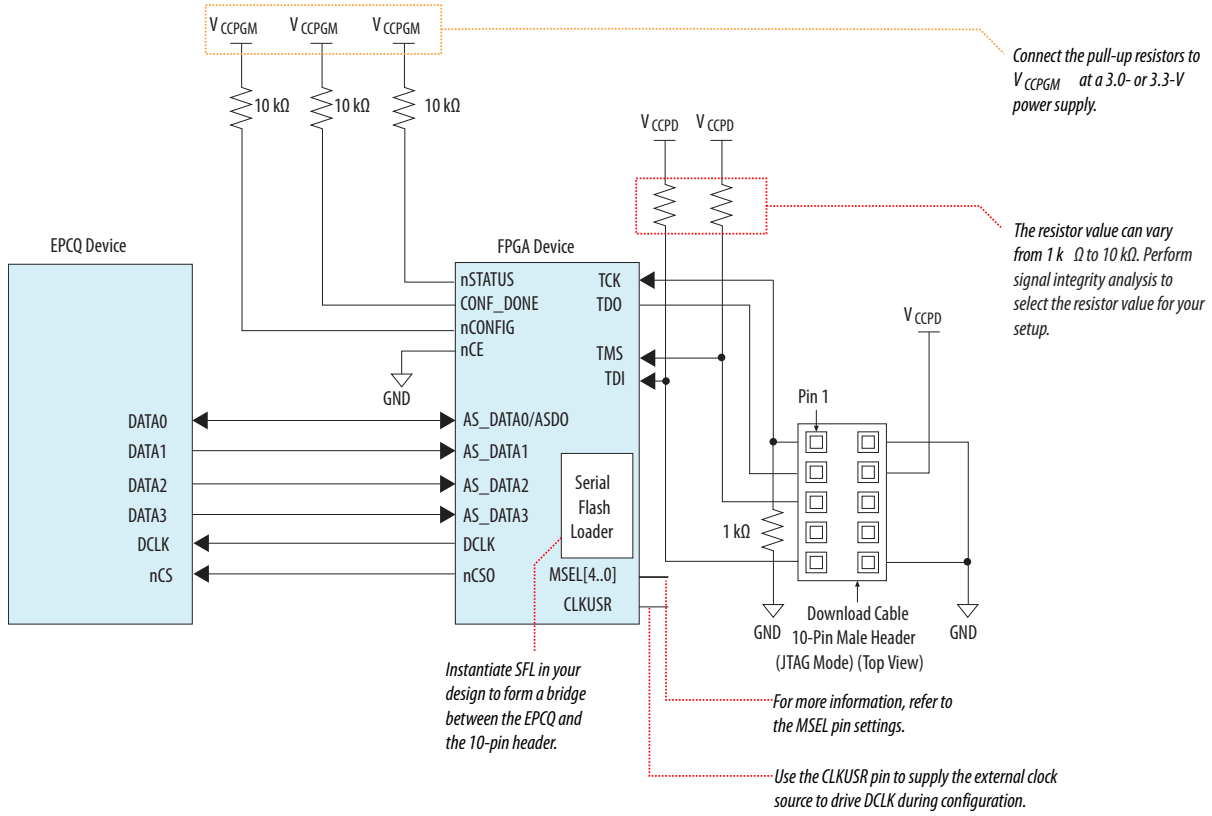
Figure 8-8: Connection Setup for Programming the EPCS Using the JTAG Interface



Programming EPCQ Using the JTAG Interface

To program an EPCQ device using the JTAG interface, connect the device as shown in the following figure.

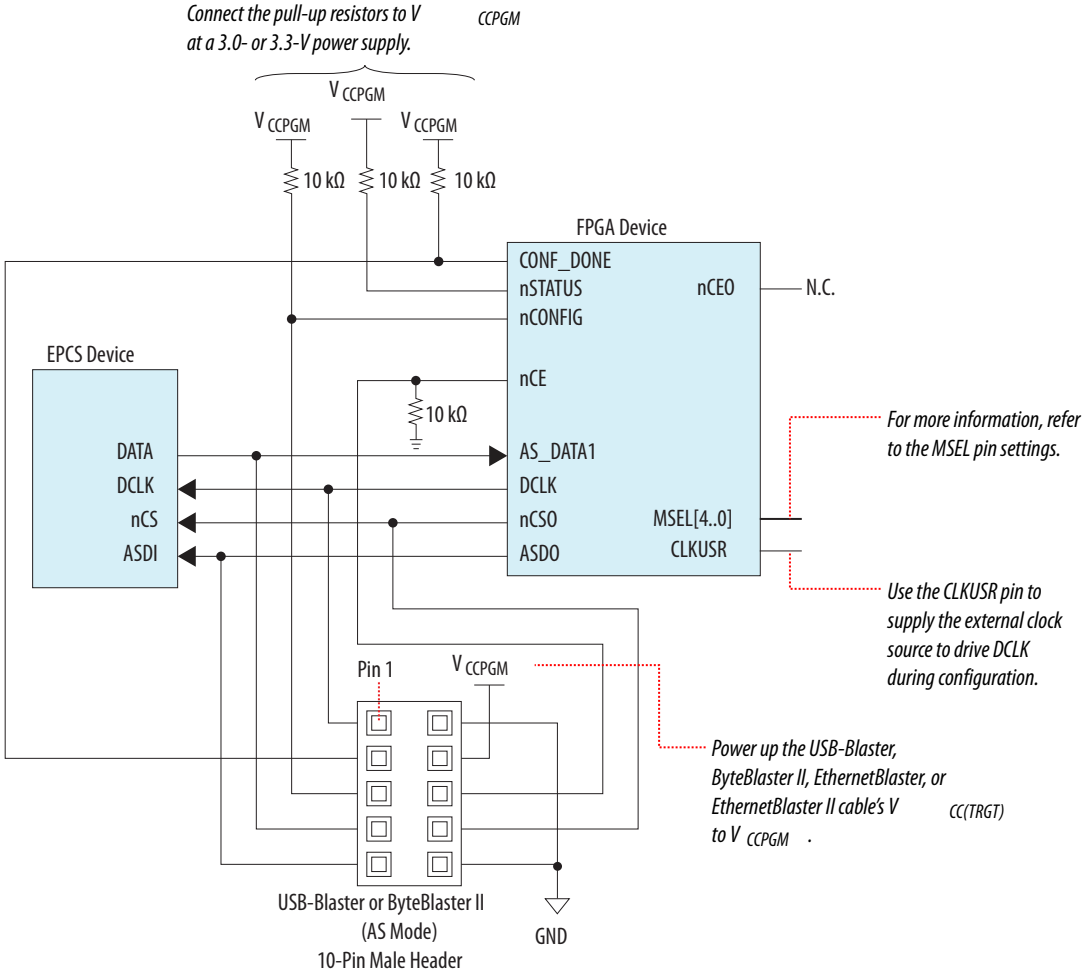
Figure 8-9: Connection Setup for Programming the EPCQ Using the JTAG Interface



Programming EPCS Using the Active Serial Interface

To program an EPCS device using the AS interface, connect the device as shown in the following figure.

Figure 8-10: Connection Setup for Programming the EPCS Using the AS Interface

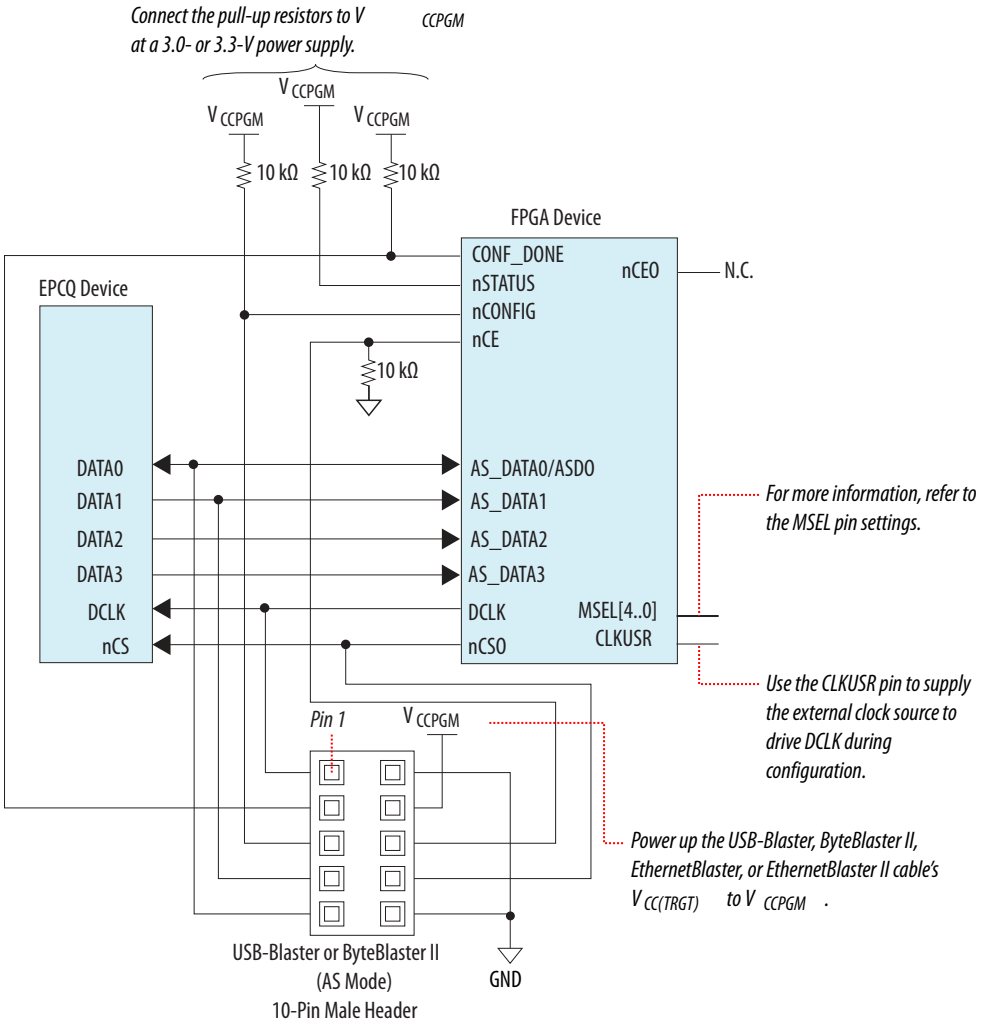


Programming EPCQ Using the Active Serial Interface

To program an EPCQ device using the AS interface, connect the device as shown in the following figure.

Figure 8-11: Connection Setup for Programming the EPCQ Using the AS Interface

Using the AS header, the programmer serially transmits the operation commands and configuration bits to the EPCQ on DATA0. This is equivalent to the programming operation for the EPCS.



When programming the EPCS and EPCQ devices, the download cable disables access to the AS interface by driving the nCE pin high. The nCONFIG line is also pulled low to hold the Arria V device in the reset stage. After programming completes, the download cable releases nCE and nCONFIG, allowing the pull-down and pull-up resistors to drive the pin to GND and V_{CCPGM}, respectively.

During the EPCQ programming using the download cable, DATA0 transfers the programming data, operation command, and address information from the download cable into the EPCQ. During the EPCQ verification using the download cable, DATA1 transfers the programming data back to the download cable.

Passive Serial Configuration

The PS configuration scheme uses an external host. You can use a microprocessor, MAX II device, MAX V device, or a host PC as the external host.

You can use an external host to control the transfer of configuration data from an external storage such as flash memory to the FPGA. The design that controls the configuration process resides in the external host.

You can store the configuration data in Programmer Object File (**.pof**), **.rbf**, **.hex**, or **.ttf**. If you are using configuration data in **.rbf**, **.hex**, or **.ttf**, send the LSB of each data byte first. For example, if the **.rbf** contains the byte sequence 02 1B EE 01 FA, the serial data transmitted to the device must be 0100-0000 1101-1000 0111-0111 1000-0000 0101-1111.

You can use the PFL megafunction with a MAX II or MAX V device to read configuration data from the flash memory device and configure the Arria V device.

For a PC host, connect the PC to the device using a download cable such as the Altera USB-Blaster USB port, ByteBlaster II parallel port, EthernetBlaster, and EthernetBlaster II download cables.

The configuration data is shifted serially into the `DATA0` pin of the device.

If you are using the Quartus II programmer and the `CLKUSR` pin is enabled, you do not need to provide a clock source for the pin to initialize your device.

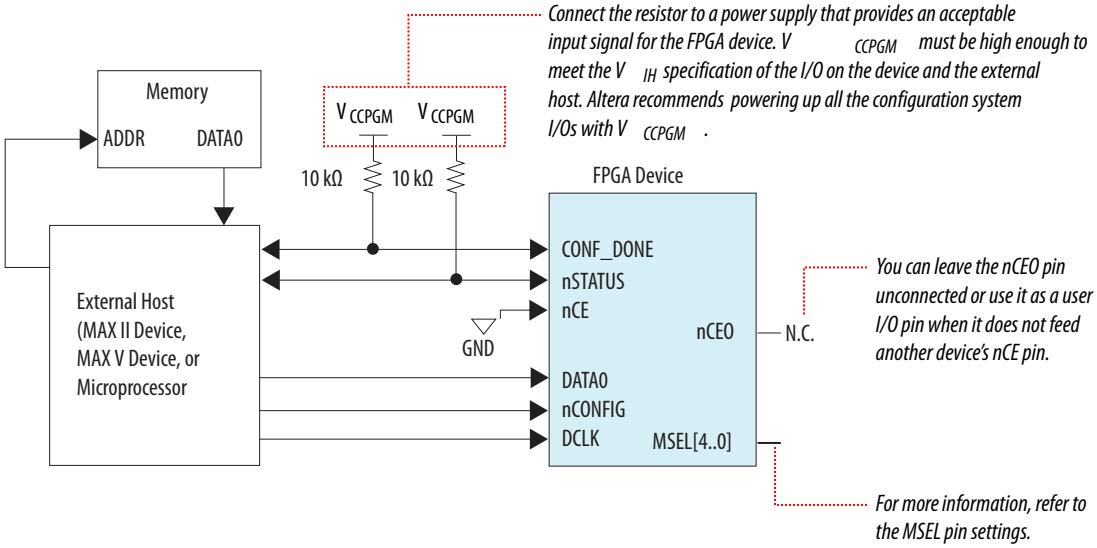
  Provides more information about the PS configuration timing.

Passive Serial Single-Device Configuration Using an External Host

To configure an Arria V device, connect the device to an external host, as shown in the following figure.

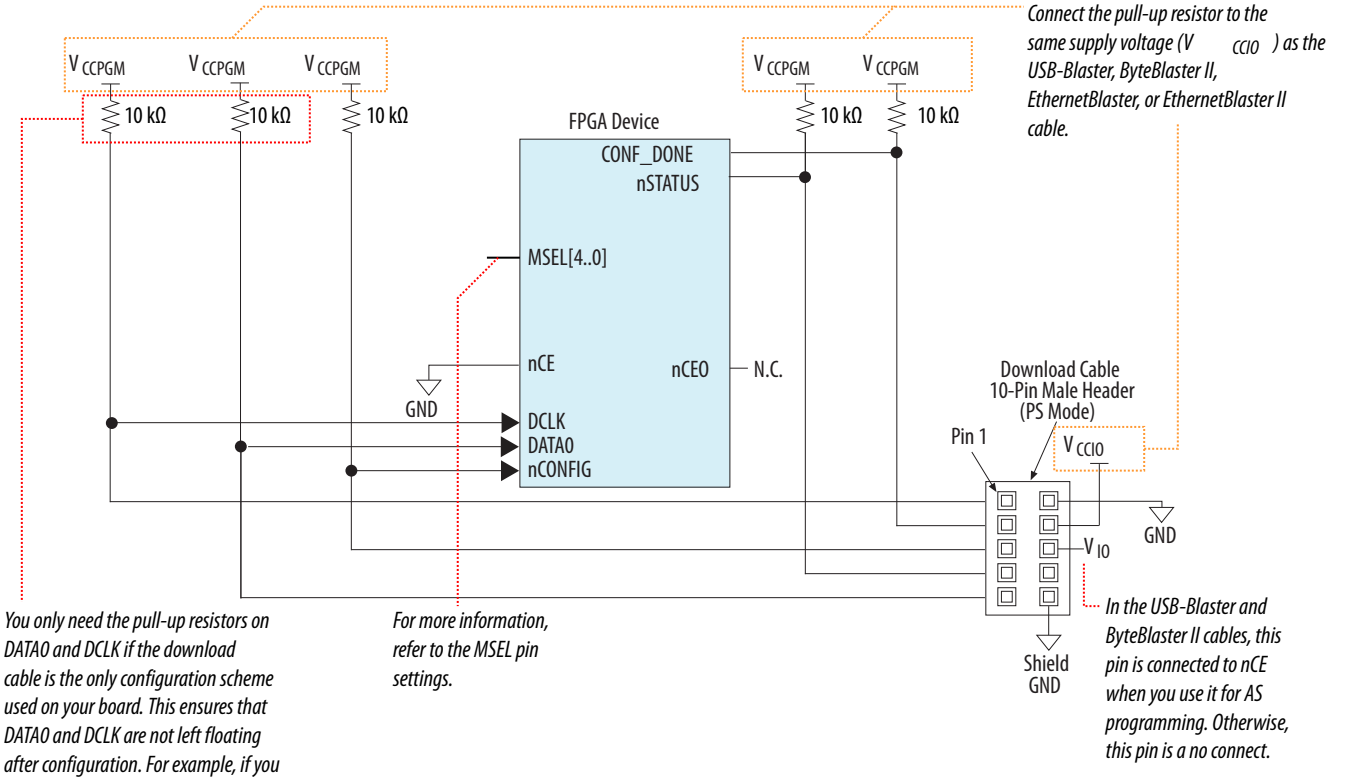
Figure 8-12: Single Device PS Configuration Using an External Host



Passive Serial Single-Device Configuration Using an Altera Download Cable

To configure an Arria V device, connect the device to a download cable, as shown in the following figure.

Figure 8-13: Single Device PS Configuration Using an Altera Download Cable



Passive Serial Multi-Device Configuration

You can configure multiple Arria V devices that are connected in a chain.

Pin Connections and Guidelines

Observe the following pin connections and guidelines for this configuration setup:

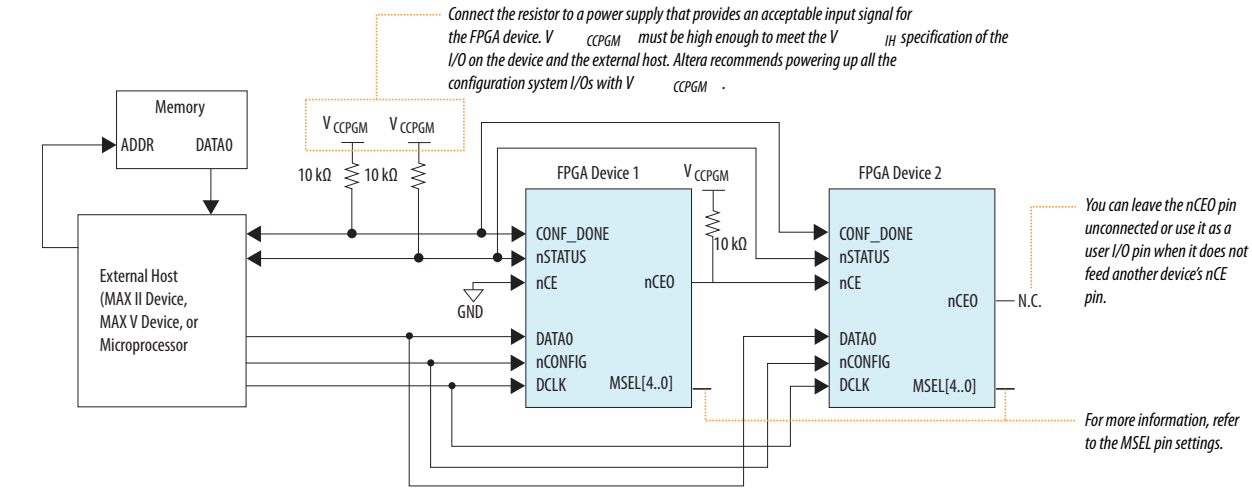
- Tie the following pins of all devices in the chain together:
  - nCONFIG
  - nSTATUS
  - DCLK
  - DATA0
  - CONF_DONE

  By tying the CONF_DONE and nSTATUS pins together, the devices initialize and enter user mode at the same time. If any device in the chain detects an error, configuration stops for the entire chain and you must reconfigure all the devices. For example, if the first device in the chain flags an error on the nSTATUS pin, it resets the chain by pulling its nSTATUS pin low.
- If you are configuring the devices in the chain using the same configuration data, the devices must be of the same package and density.

Using Multiple Configuration Data

To configure multiple Arria V devices in a chain using multiple configuration data, connect the devices to the external host as shown in the following figure.

Figure 8-14: Multiple Device PS Configuration when Both Devices Receive Different Sets of Configuration Data

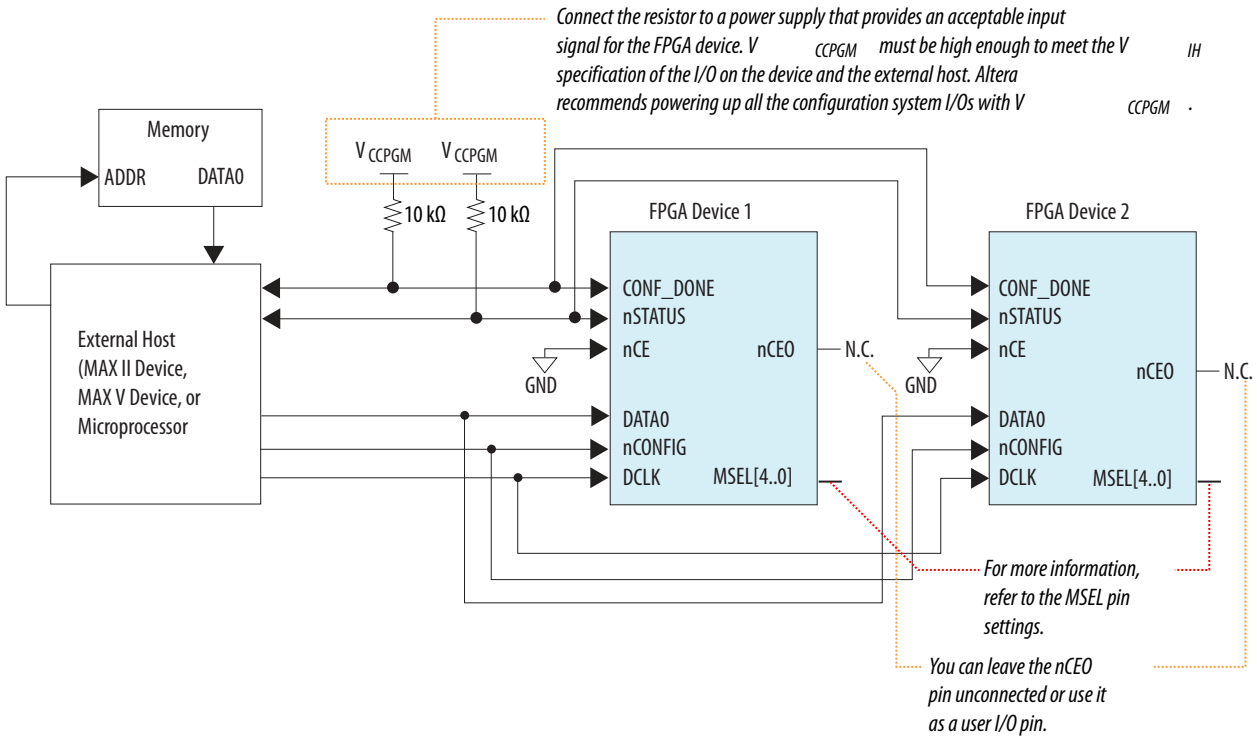


After a device completes configuration, its nCEO pin is released low to activate the nCE pin of the next device in the chain. Configuration automatically begins for the second device in one clock cycle.

Using One Configuration Data

To configure multiple Arria V devices in a chain using one configuration data, connect the devices to an external host, as shown in the following figure.

Figure 8-15: Multiple Device PS Configuration When Both Devices Receive the Same Set of Configuration Data

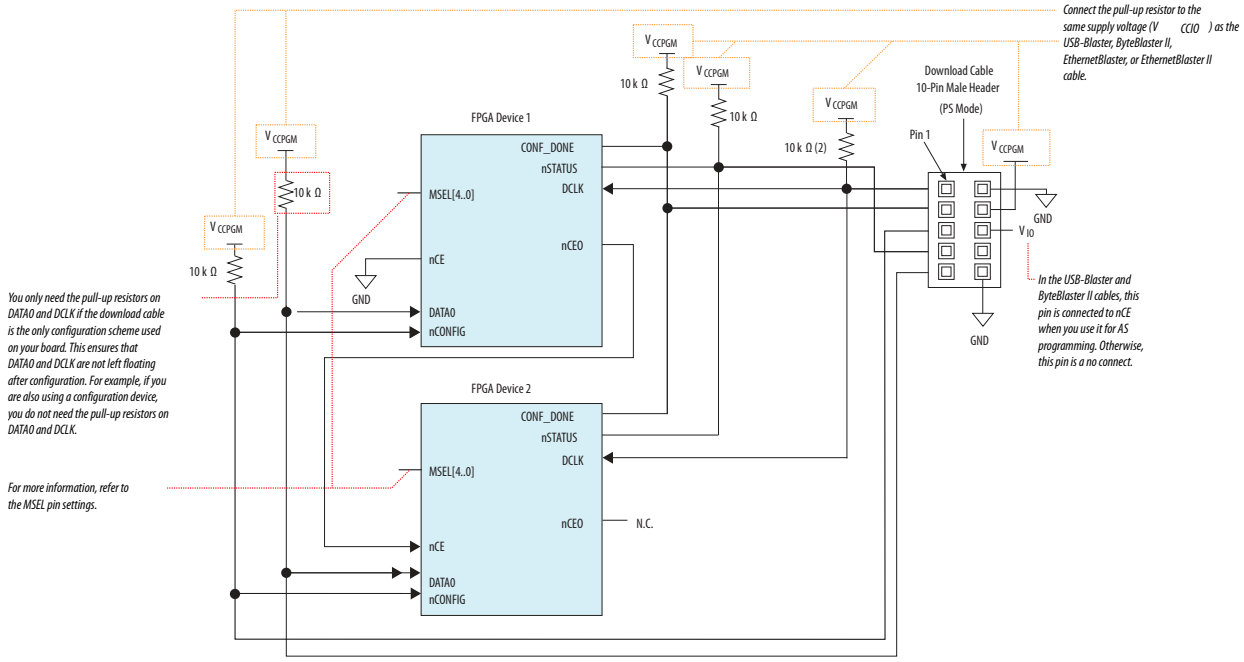


The nCE pins of the devices in the chain are connected to GND, allowing configuration for these devices to begin and end at the same time.

Using PC Host and Download Cable

To configure multiple Arria V devices, connect the devices to a download cable, as shown in the following figure.

Figure 8-16: Multiple Device PS Configuration Using an Altera Download Cable



When a device completes configuration, its nCEO pin is released low to activate the nCE pin of the next device. Configuration automatically begins for the second device.

JTAG Configuration

In Arria V devices, JTAG instructions take precedence over other configuration schemes.

The Quartus II software generates an SRAM Object File (**.sof**) that you can use for JTAG configuration using a download cable in the Quartus II software programmer. Alternatively, you can use the JRunner software with **.rbf** or a JAM™ Standard Test and Programming Language (STAPL) Format File (**.jam**) or JAM Byte Code File (**.jbc**) with other third-party programmer tools.

JTAG Single-Device Configuration

To configure a single device in a JTAG chain, the programming software sets the other devices to the bypass mode. A device in a bypass mode transfers the programming data from the TDI pin to the TDO pin through a single bypass register. The configuration data is available on the TDO pin one clock cycle later.

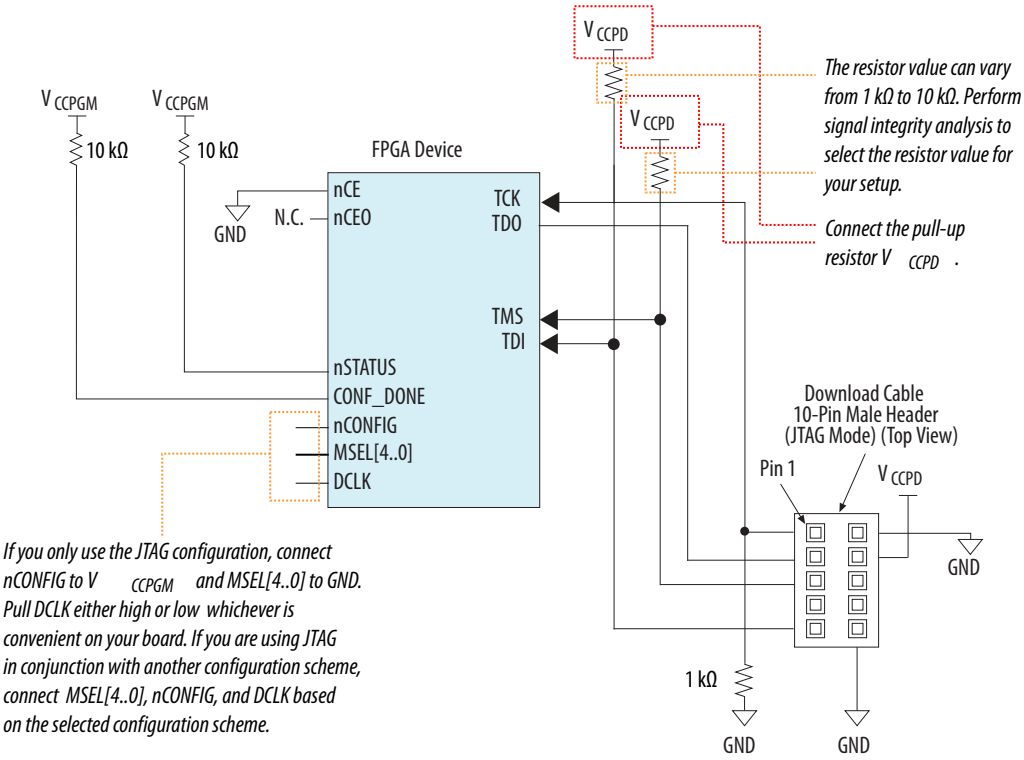
The Quartus II software can use the CONF_DONE pin to verify the completion of the configuration process through the JTAG port:

- CONF_DONE pin is low—indicates that configuration has failed.
- CONF_DONE pin is high—indicates that configuration was successful.

After the configuration data is transmitted serially using the JTAG TDI port, the TCK port is clocked an additional 1,222 cycles to perform device initialization.

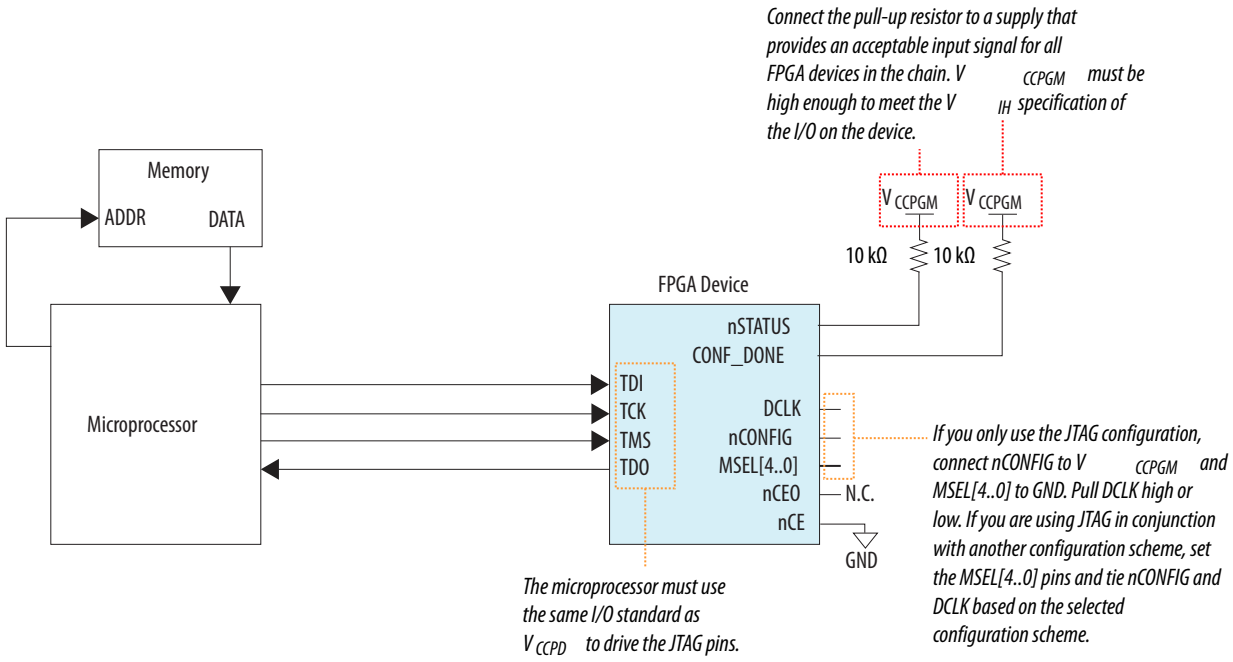
To configure an Arria V device using a download cable, connect the device as shown in the following figure.

Figure 8-17: JTAG Configuration of a Single Device Using a Download Cable



To configure Arria V device using a microprocessor, connect the device as shown in the following figure. You can use JRunner as your software driver.

Figure 8-18: JTAG Configuration of a Single Device Using a Microprocessor



Related Information

AN 414: The JRunner Software Driver: An Embedded Solution for PLD JTAG Configuration

JTAG Multi-Device Configuration

You can configure multiple devices in a JTAG chain.

Pin Connections and Guidelines

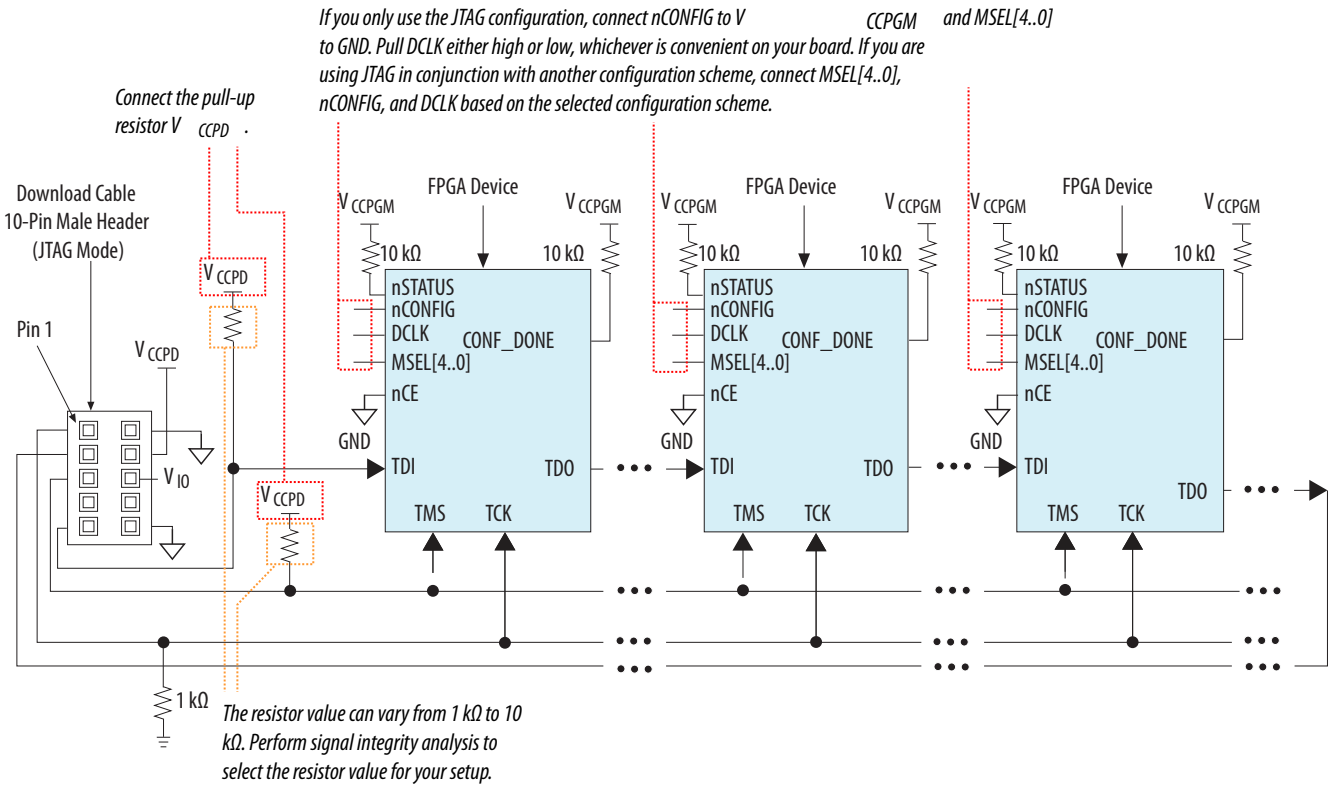
Observe the following pin connections and guidelines for this configuration setup:

- Isolate the `CONF_DONE` and `nSTATUS` pins to allow each device to enter user mode independently.
- One JTAG-compatible header is connected to several devices in a JTAG chain. The number of devices in the chain is limited only by the drive capability of the download cable.
- If you have four or more devices in a JTAG chain, buffer the `TCK`, `TDI`, and `TMS` pins with an on-board buffer. You can also connect other Altera devices with JTAG support to the chain.
- JTAG-chain device programming is ideal when the system contains multiple devices or when testing your system using the JTAG boundary-scan testing (BST) circuitry.

Using a Download Cable

The following figure shows a multi-device JTAG configuration.

Figure 8-19: JTAG Configuration of Multiple Devices Using a Download Cable



Related Information

AN 656: Combining Multiple Configuration Schemes
Provides more information about combining JTAG configuration with other configuration schemes.

CONFIG_IO JTAG Instruction

The CONFIO_IO JTAG instruction allows you to configure the I/O buffers using the JTAG port before or during device configuration. When you issue this instruction, it interrupts configuration and allows you to issue all JTAG instructions. Otherwise, you can only issue the BYPASS, IDCODE, and SAMPLE JTAG instructions.

You can use the CONFIO_IO JTAG instruction to interrupt configuration and perform board-level testing. After the board-level testing is completed, you must reconfigure your device. Use the following methods to reconfigure your device:

- JTAG interface—issue the PULSE_NCONFIG JTAG instruction.
- FPP, PS, or AS configuration scheme—pulse the nCONFIG pin low.

Configuration Data Compression

Arria V devices can receive compressed configuration bitstream and decompress the data in real-time during configuration. Preliminary data indicates that compression typically reduces the configuration file size by 30% to 55% depending on the design.

Decompression is supported in all configuration schemes except the JTAG configuration scheme.

You can enable compression before or after design compilation.

Enabling Compression Before Design Compilation

To enable compression before design compilation, follow these steps:

1. On the Assignment Menu, click **Device**.
2. Select your Arria V device and then click **Device and Pin Options**.
3. In the **Device and Pin Options** window, select **Configuration** under the **Category** list and turn on **Generate compressed bitstreams**.

Enabling Compression After Design Compilation

To enable compression after design compilation, follow these steps:

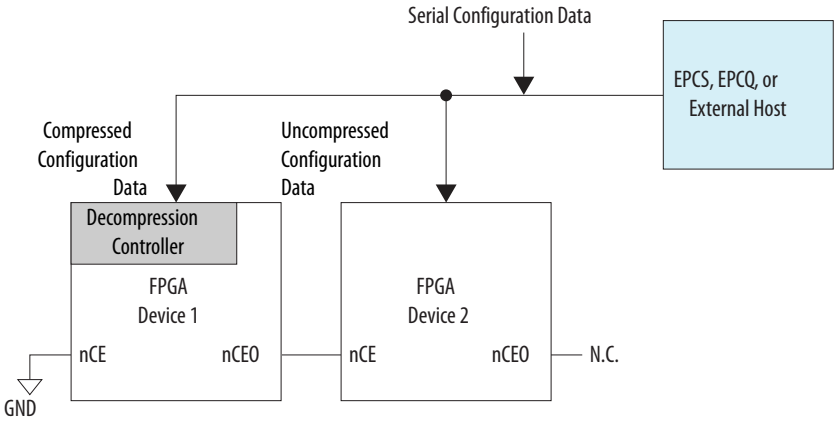
1. On the File menu, click **Convert Programming Files**.
2. Select the programming file type (**.pof**, **.sof**, **.hex**, **.hexout**, **.rbf**, or **.ttf**). For POF output files, select a configuration device.
3. Under the **Input files to convert** list, select **SOF Data**.
4. Click **Add File** and select an Arria V device **.sof**.
5. Select the name of the file you added to the **SOF Data** area and click **Properties**.
6. Turn on the **Compression** check box.

Using Compression in Multi-Device Configuration

The following figure shows a chain of two Arria V devices. Compression is only enabled for the first device.

This setup is supported by the AS or PS multi-device configuration only.

Figure 8-20: Compressed and Uncompressed Serial Configuration Data in the Same Configuration File

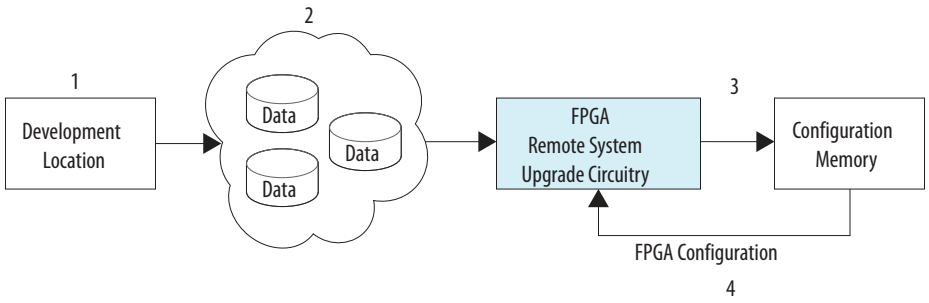


For the FPP configuration scheme, a combination of compressed and uncompressed configuration in the same multi-device configuration chain is not allowed because of the difference on the DCLK-to-DATA[] ratio.

Remote System Upgrades

Arria V devices contain dedicated remote system upgrade circuitry. You can use this feature to upgrade your system from a remote location.

Figure 8-21: Arria V Remote System Upgrade Block Diagram



You can design your system to manage remote upgrades of the application configuration images in the configuration device. The following list is the sequence of the remote system upgrade:

1. The logic (embedded processor or user logic) in the Arria V device receives a configuration image from a remote location. You can connect the device to the remote source using communication protocols such as TCP/IP, PCI, user datagram protocol (UDP), UART, or a proprietary interface.
2. The logic stores the configuration image in non-volatile configuration memory.
3. The logic starts reconfiguration cycle using the newly received configuration image.
4. When an error occurs, the circuitry detects the error, reverts to a safe configuration image, and provides error status to your design.

Configuration Images

Each Arria V device in your system requires one factory image. The factory image is a user-defined configuration image that contains logic to perform the following:

- Processes errors based on the status provided by the dedicated remote system upgrade circuitry.
- Communicates with the remote host, receives new application images, and stores the images in the local non-volatile memory device.
- Determines the application image to load into the Arria V device.
- Enables or disables the user watchdog timer and loads its time-out value.
- Instructs the dedicated remote system upgrade circuitry to start a reconfiguration cycle.

You can also create one or more application images for the device. An application image contains selected functionalities to be implemented in the target device.

Store the images at the following locations in the EPCS or EPCQ devices:

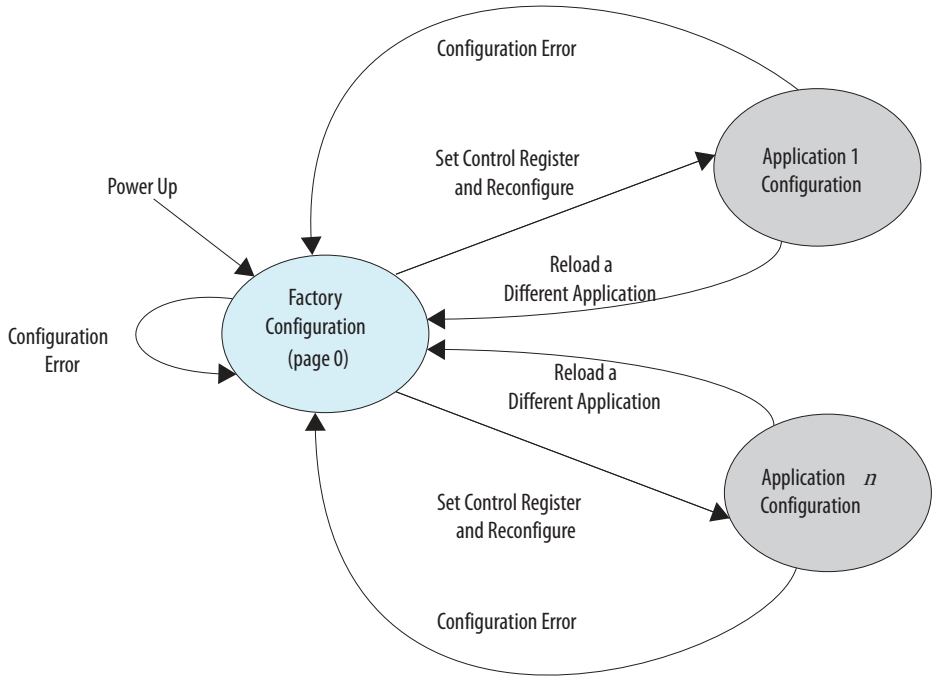
- Factory configuration image—`PGM[23..0]` = 24'h000000 start address on the EPCS or EPCQ device.
- Application configuration image—any sector boundary. Altera recommends that you store only one image at one sector boundary.

When you are using EPCQ 256, ensure that the application configuration image address granularity is 32'h00000100. The granularity requirement is having the most significant 24 bits of the 32 bits start address written to `PGM[23..0]` bits.

Note: If you are not using the Quartus II software or SRunner software for EPCQ 256 programming, put your EPCQ 256 device into four-byte addressing mode before you program and configure your device.

Configuration Sequence in the Remote Update Mode

Figure 8-22: Transitions Between Factory and Application Configurations in Remote Update Mode



Related Information

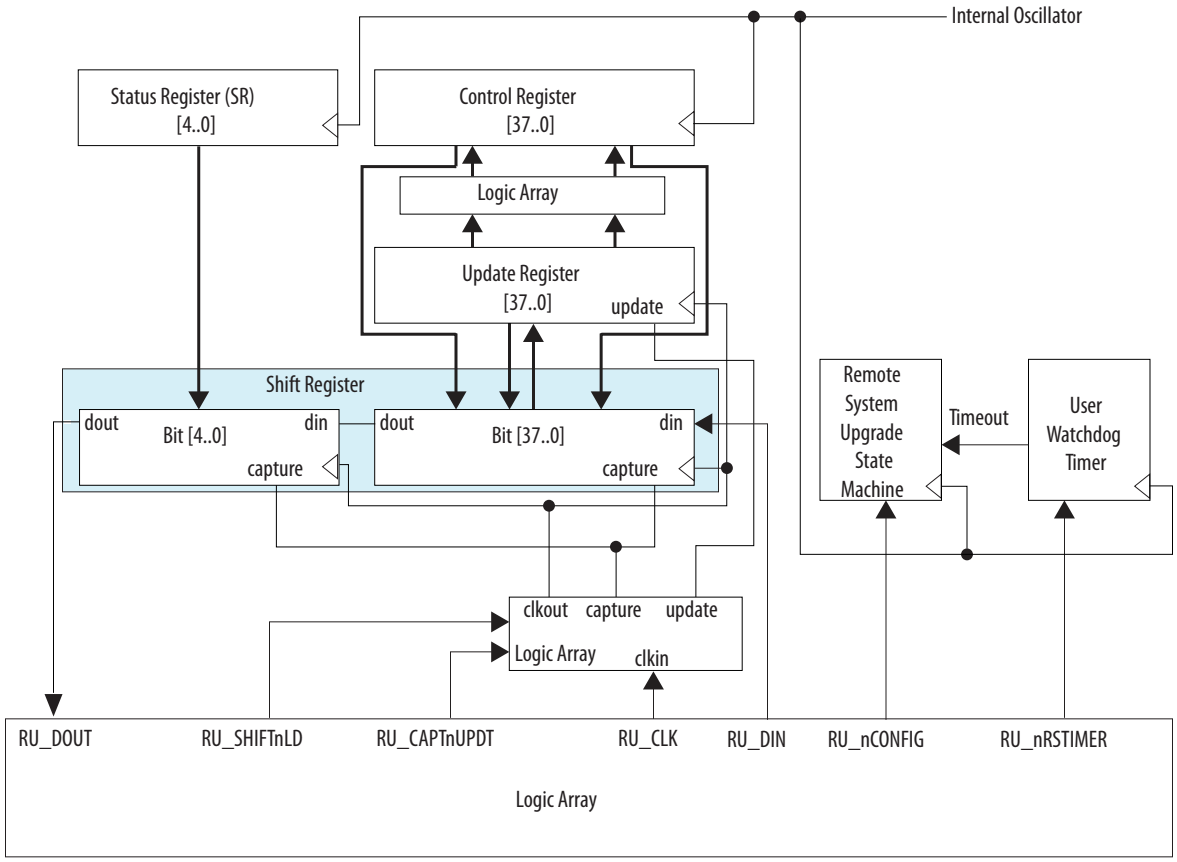
Remote System Upgrade State Machine on page 8-38
A detailed description of the configuration sequence in the remote update mode.

Remote System Upgrade Circuitry

The remote system upgrade circuitry contains the remote system upgrade registers, watchdog timer, and a state machine that controls these components.

Note: If you are using the ALTREMOTE_UPDATE megafunction, the megafunction controls the `RU_DOUT`, `RU_SHIFTnLD`, `RU_CAPTnUPDT`, `RU_CLK`, `RU_DIN`, `RU_nCONFIG`, and `RU_nRSTIMER` signals internally to perform all the related remote system upgrade operations.

Figure 8-23: Remote System Upgrade Circuitry



Related Information

Arria V Device Datasheet
Provides more information about remote system upgrade circuitry timing specifications.

Enabling Remote System Upgrade Circuitry

To enable the remote system upgrade feature, follow these steps:

1. Select **Active Serial x1/x4** or **Configuration Device** from the Configuration scheme list in the **Configuration** page of the **Device and Pin Options** dialog box in the Quartus II software.
2. Select **Remote** from the Configuration mode list in the **Configuration** page of the **Device and Pin Options** dialog box in the Quartus II software.

Enabling this feature automatically turns on the **Auto-restart configuration after error** option.

Altera-provided ALTREMOTE_UPDATE megafunction provides a memory-like interface to the remote system upgrade circuitry and handles the shift register read and write protocol in the Arria V device logic.

Related Information

Remote System Upgrade (ALTREMOTE_UPDATE) Megafunction User Guide

Remote System Upgrade Registers

Table 8-9: Remote System Upgrade Registers

Register	Description
Shift	Accessible by the logic array and clocked by RU_CLK. • Bits[4..0]—Contents of the status register are shifted into these bits. • Bits[37..0]—Contents of the update and control registers are shifted into these bits.
Control	This register is clocked by the 10-MHz internal oscillator. The contents of this register are shifted to the shift register for the user logic in the application configuration to read. When reconfiguration is triggered, this register is updated with the contents of the update register.
Update	This register is clocked by RU_CLK. The factory configuration updates this register by shifting data into the shift register and issuing an update. When reconfiguration is triggered, the contents of the update register are written to the control register.
Status	After each reconfiguration, the remote system upgrade circuitry updates this register to indicate the event that triggered the reconfiguration. This register is clocked by the 10-MHz internal oscillator.

Related Information

- **Control Register** on page 8-37
- **Status Register** on page 8-38

Control Register

Table 8-10: Control Register Bits

Bit	Name	Reset Value[29]	Description
0	AnF	1'b0	Application not Factory bit. Indicates the configuration image type currently loaded in the device; **0** for factory image and **1** for application image. When this bit is **1**, the access to the control register is limited to read only and the watchdog timer is enabled. Factory configuration design must set this bit to **1** before triggering reconfiguration using an application configuration image.
1..24	PGM[0..23]	24'h000000	Upper 24 bits of AS configuration start address (StAdd[31..8]), the 8 LSB are zero.

[29] This is the default value after the device exits POR and during reconfiguration back to the factory configuration image.

Bit	Name	Reset Value[29]	Description
25	Wd_en	1'b0	User watchdog timer enable bit. Set this bit to **1** to enable the watchdog timer.
26..37	Wd_timer[11..0]	12'b000000000000	User watchdog time-out value.

Status Register

Table 8-11: Status Register Bits

Bit	Name	Reset Value[30]	Description
0	CRC	1'b0	When set to **1**, indicates CRC error during application configuration.
1	nSTATUS	1'b0	When set to **1**, indicates that nSTATUS is asserted by an external device due to error.
2	Core_nCONFIG	1'b0	When set to **1**, indicates that reconfiguration has been triggered by the logic array of the device.
3	nCONFIG	1'b0	When set to **1**, indicates that nCONFIG is asserted.
4	Wd	1'b0	When set to **1**, indicates that the user watchdog time-out.

Remote System Upgrade State Machine

The operation of the remote system upgrade state machine is as follows:

1. After power-up, the remote system upgrade registers are reset to **0** and the factory configuration image is loaded.
2. The user logic sets the AnF bit to **1** and the start address of the application image to be loaded. The user logic also writes the watchdog timer settings.
3. When the configuration reset (RU_CONFIG) goes low, the state machine updates the control register with the contents of the update register, and triggers reconfiguration using the application configuration image.
4. If error occurs, the state machine falls back to the factory image. The control and update registers are reset to **0**, and the status register is updated with the error information.
5. After successful reconfiguration, the system stays in the application configuration.

User Watchdog Timer

The user watchdog timer prevents a faulty application configuration from stalling the device indefinitely. You can use the timer to detect functional errors when an application configuration is successfully loaded

[29] This is the default value after the device exits POR and during reconfiguration back to the factory configuration image.
[30] After the device exits POR and power-up, the status register content is 5'b00000.

into the device. The timer is automatically disabled in the factory configuration; enabled in the application configuration.

Note: If you do not want this feature in the application configuration, you need to turn off this feature by setting the `Wd_en` bit to **1'b0** in the update register during factory configuration user mode operation. You cannot disable this feature in the application configuration.

The counter is 29 bits wide and has a maximum count value of 2^{29}. When specifying the user watchdog timer value, specify only the most significant 12 bits. The granularity of the timer setting is 2^{17} cycles. The cycle time is based on the frequency of the user watchdog timer internal oscillator.

The timer begins counting as soon as the application configuration enters user mode. When the timer expires, the remote system upgrade circuitry generates a time-out signal, updates the status register, and triggers the loading of the factory configuration image. To reset the time, assert `RU_nRSTIMER`.

Related Information

Arria V Device Datasheet
Provides more information about the operating range of the user watchdog internal oscillator's frequency.

Design Security

The Arria V design security feature supports the following capabilities:

- Enhanced built-in advanced encryption standard (AES) decryption block to support 256-bit key industry-standard design security algorithm (FIPS-197 Certified)
- Volatile and non-volatile key programming support
- Secure operation mode for both volatile and non-volatile key through tamper protection bit setting
- Limited accessible JTAG instruction during power-up in the JTAG secure mode
- Supports board-level testing
- Supports in-socket key programming for non-volatile key
- Available in all configuration schemes except JTAG
- Supports both remote system upgrades and compression features

The Arria V design security feature provides the following security protection for your designs:

- Security against copying—the security key is securely stored in the Arria V device and cannot be read out through any interface. In addition, as configuration file read-back is not supported in Arria V devices, your design information cannot be copied.
- Security against reverse engineering—reverse engineering from an encrypted configuration file is very difficult and time consuming because the Arria V configuration file formats are proprietary and the file contains millions of bits that require specific decryption.
- Security against tampering—After you set the tamper protection bit, the Arria V device can only accept configuration files encrypted with the same key. Additionally, programming through the JTAG interface and configuration interface is blocked.

When you use compression with the design security feature, the configuration file is first compressed and then encrypted using the Quartus II software. During configuration, the device first decrypts and then decompresses the configuration file.

When you use design security with Arria V devices in an FPP configuration scheme, it requires a different `DCLK-to-DATA[]` ratio.

ALTCHIP_ID Megafunction

The ALTCHIP_ID megafunction provides the following features:

- Acquiring the chip ID of an FPGA device.
- Allowing you to identify your device in your design as part of a security feature to protect your design from an unauthorized device.

Related Information

ALTCHIP_ID Megafunction User Guide

JTAG Secure Mode

When you enable the tamper-protection bit, Arria V devices are in the JTAG secure mode after power-up. During this mode, many JTAG instructions are disabled. Arria V devices only allow mandatory JTAG 1149.1 instructions to be exercised. These JTAG instructions are `SAMPLE/PRELOAD`, `BYPASS`, `EXTEST`, and optional instructions such as `IDCODE` and `SHIFT_EDERROR_REG`.

To enable the access of other JTAG instructions such as `USERCODE`, `HIGHZ`, `CLAMP`, `PULSE_nCONFIG`, and `CONFIG_IO`, you must issue the `UNLOCK` instruction to deactivate the JTAG secure mode. You can issue the `LOCK` instruction to put the device back into JTAG secure mode. You can only issue both the `LOCK` and `UNLOCK` JTAG instructions during user mode.

Related Information

- **Supported JTAG Instruction** on page 10-3
  Provides more information about JTAG binary instruction code related to the `LOCK` and `UNLOCK` instructions.
- **JTAG Boundary-Scan Testing in Arria V Devices**
  Provides more information about JTAG binary instruction code related to the `LOCK` and `UNLOCK` instructions.

Security Key Types

Arria V devices offer two types of keys—volatile and non-volatile. The following table lists the differences between the volatile key and non-volatile keys.

Table 8-12: Security Key Types

Key Types	Key Programmability	Power Supply for Key Storage	Programming Method
Volatile	• Reprogrammable • Erasable	Required external battery, V_{CCBAT} (31)	On-board
Non-volatile	One-time programming	Does not require an external battery	On-board and in-socket programming (32)

(31) V_{CCBAT} is a dedicated power supply for volatile key storage. V_{CCBAT} continuously supplies power to the volatile register regardless of the on-chip supply condition.
(32) Third-party vendors offer in-socket programming.

Both non-volatile and volatile key programming offers protection from reverse engineering and copying. If you set the tamper-protection bit, the design is also protected from tampering.

You can perform key programming through the JTAG pins interface. Ensure that the nSTATUS pin is released high before any key-programming attempts.

Note: To clear the volatile key, issue the KEY_CLR_VREG JTAG instruction. To verify the volatile key has been cleared, issue the KEY_VERIFY JTAG instruction.

Related Information

  Provides more information about the V_{CCBAT} pin connection recommendations.
- **Arria V GZ Device Family Pin Connection Guidelines**
  Provides more information about the V_{CCBAT} pin connection recommendations.
- **Arria V Device Datasheet**
  Provides more information about battery specifications.

Security Modes

Table 8-13: Supported Security Modes

There is no impact to the configuration time required when compared with unencrypted configuration modes except FPP with AES (and/or decompression), which requires a DCLK that is up to ×4 the data rate.

Security Mode	Tamper Protection Bit Setting	Device Accepts Unencrypted File	Device Accepts Encrypted File	Security Level
No key	—	Yes	No	—
Volatile Key	—	Yes	Yes	Secure
Volatile Key with Tamper Protection Bit Set	Set	No	Yes	Secure with tamper resistant
Non-volatile Key	—	Yes	Yes	Secure
Non-volatile Key with Tamper Protection Bit Set	Set	No	Yes	Secure with tamper resistant

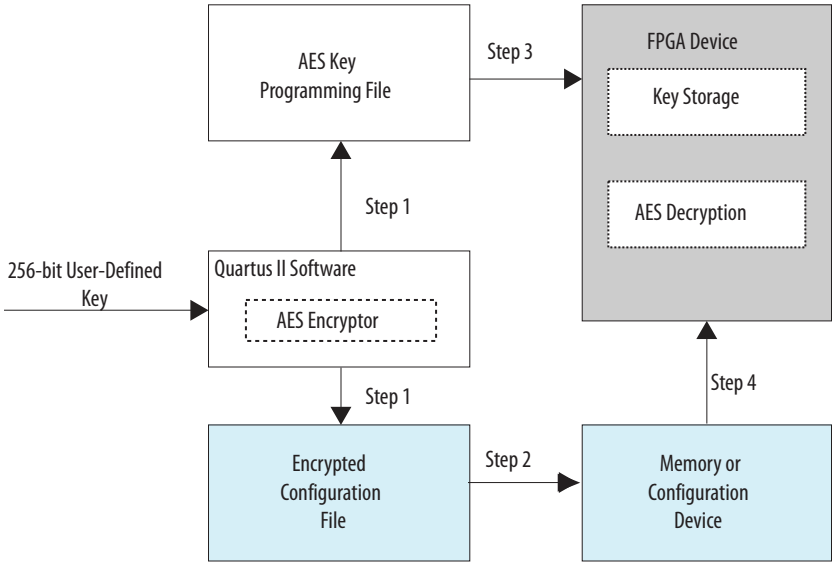
The use of unencrypted configuration bitstream in the volatile key and non-volatile key security modes is supported for board-level testing only.

Note: For the volatile key with tamper protection bit set security mode, Arria V devices do not accept the encrypted configuration file if the volatile key is erased. If the volatile key is erased and you want to reprogram the key, you must use the volatile key security mode.

Enabling the tamper protection bit disables the test mode in Arria V devices and disables programming through the JTAG interface. This process is irreversible and prevents Altera from carrying out failure analysis.

Design Security Implementation Steps

Figure 8-24: Design Security Implementation Steps



To carry out secure configuration, follow these steps:

1. The Quartus II software generates the design security key programming file and encrypts the configuration data using the user-defined 256-bit security key.
2. Store the encrypted configuration file in the external memory.
3. Program the AES key programming file into the Arria V device through a JTAG interface.
4. Configure the Arria V device. At the system power-up, the external memory device sends the encrypted configuration file to the Arria V device.

Document Revision History

Date	Version	Changes
January 2015	2015.01.23	• Added the Transmitting Configuration Data section. • Updated the Configuration Images section.

Date	Version	Changes
June 2014	2014.06.30	• Updated Figure 8-17: JTAG Configuration of a Single Device Using a Download Cable. • Updated Figure 8-19: JTAG Configuration of Multiple Devices Using a Download Cable. • Updated the maximum clock rate for Partial Reconfiguration in Table 8-1. • Updated the MSEL pin settings recommendation in the MSEL Pin Settings section.
January 2014	2014.01.10	• Added a link to the FPGA Manager chapter for details about the MSEL pin settings for the HPS in SoC FPGA devices. • Updated the V_{CCPD} Pin section. • Updated the Enabling Remote System Upgrade Circuitry section. • Updated the Configuration Pin Summary section. • Updated Figure 8-3, Figure 8-7, and Figure 8-14.
June 2013	2013.06.11	Updated the Configuration Error Handling section.
May 2013	2013.05.10	Removed support for active serial multi-device configuration using the same configuration data.
May 2013	2013.05.06	• Added link to the known document issues in the Knowledge Base. • Added the ALTCHIP_ID megafunction section. • Updated "Connection Setup for Programming the EPCS Using the JTAG Interface" and "Connection Setup for Programming the EPCQ Using the JTAG Interface" figures. • Added the `nIO_PULLUP` pin in Table 8-3: Configuration Pin Summary for Arria V Devices. • Added links for AS, PS, FPP, and JTAG configuration timing to device datasheet. • Moved all links to the Related Information section of respective topics for easy reference.
November 2012	2012.11.19	• Added configuration modes and features for Arria V devices. • Added FPP x32 for Arria V GZ devices. • Added DATA[31..16] for Arria V GZ devices. • Reorganized content and updated template.
June 2012	2.0	Restructured the chapter.
November 2011	1.1	Minor text edits.
October 2011	1.0	Initial release.

SEU Mitigation for Arria V Devices

9

2015.01.23

AV-52009

This chapter describes the error detection features in Arria V devices. You can use these features to mitigate single event upset (SEU) or soft errors.

Related Information

Arria V Device Handbook: Known Issues
Lists the planned updates to the *Arria V Device Handbook* chapters.

Error Detection Features

The on-chip error detection CRC circuitry allows you to perform the following operations without any impact on the fitting or performance of the device:

- Auto-detection of CRC errors during configuration.
- Optional CRC error detection and identification in user mode.
- Testing of error detection functions by deliberately injecting errors through the JTAG interface.

Configuration Error Detection

When the Quartus II software generates the configuration bitstream, the software also computes a 16-bit CRC value for each frame. A configuration bitstream can contain more than one CRC values depending on the number of data frames in the bitstream. The length of the data frame varies for each device.

When a data frame is loaded into the FPGA during configuration, the precomputed CRC value shifts into the CRC circuitry. At the same time, the CRC engine in the FPGA computes the CRC value for the data frame and compares it against the precomputed CRC value. If both CRC values do not match, the nSTATUS pin is set to low to indicate a configuration error.

You can test the capability of this feature by modifying the configuration bitstream or intentionally corrupting the bitstream during configuration.

User Mode Error Detection

In user mode, the contents of the configured CRAM bits may be affected by soft errors. These soft errors, which are caused by an ionizing particle, are not common in Altera devices. However, high-reliability

applications that require the device to operate error-free may require that your designs account for these errors.

You can enable the error detection circuitry to detect soft errors. Each data frame stored in the CRAM contains a 32-bit precomputed CRC value. When this feature is enabled, the error detection circuitry continuously computes a 32-bit CRC value for each frame in the CRAM and compares the CRC value against the precomputed value.

- If the CRC values match, the 32-bit CRC signature in the `syndrome` register is set to zero to indicate that no error is detected.
- Otherwise, the resulting 32-bit CRC signature in the `syndrome` register is non-zero to indicate a CRC error. The `CRC_ERROR` pin is pulled high, and the error type and location are identified.

Within a frame, the error detection circuitry can detect all single-, double-, triple-, quadruple-, and quintuple-bit errors. When a single-bit or double-adjacent error is detected, the error detection circuitry reports the bit location and determines the error type for single-bit and double-adjacent errors. The probability of other error patterns is very low and the reporting of bit location is not guaranteed. The probability of more than five CRAM bits being flipped by soft errors is very low. In general, the probability of detection for all error patterns is 99.9999%. The process of error detection continues until the device is reset by setting the `nCONFIG` signal low.

Specifications

This section lists the EMR update interval, error detection frequencies, and CRC calculation time for error detection in user mode.

Minimum EMR Update Interval

The interval between each update of the error message register depends on the device and the frequency of the error detection clock. Using a lower clock frequency increases the interval time, hence increasing the time required to recover from a single event upset (SEU).

Table 9-1: Estimated Minimum EMR Update Interval in Arria V Devices

Variant	Member Code	Timing Interval (µs)
Arria V GX	A1	2.55
	A3	2.55
	A5	2.87
	A7	2.87
	B1	3.13
	B3	3.13
	B5	3.83
	B7	3.83

Variant	Member Code	Timing Interval (µs)
Arria V GT	C3	2.55
	C7	2.87
	D3	3.13
	D7	3.83
Arria V GZ	E1	2.43
	E3	2.43
	E5	2.99
	E7	2.99
Arria V SX	B3	3.83
	B5	3.83
Arria V ST	D3	3.83
	D5	3.83

Error Detection Frequency

You can control the speed of the error detection process by setting the division factor of the clock frequency in the Quartus II software. The divisor is 2^n, where n can be any value listed in the following table.

The speed of the error detection process for each data frame is determined by the following equation:

Figure 9-1: Error Detection Frequency Equation

$$\text{Error Detection Frequency} = \frac{\text{Internal Oscillator Frequency}}{2^n}$$

Table 9-2: Error Detection Frequency Range for Arria V Devices

The following table lists the frequencies and valid values of n.

Internal Oscillator Frequency	Error Detection Frequency		n	Divisor Range
	Maximum	Minimum		
100 MHz	100 MHz	390 kHz	0, 1, 2, 3, 4, 5, 6, 7, 8	1 – 256

CRC Calculation Time For Entire Device

While the CRC calculation is done on a per frame basis, it is important to know the time taken to complete CRC calculations for the entire device. The entire device detection time is the time taken to do CRC calculations on every frame in the device. This time depends on the device and the error detection clock frequency. The error detection clock frequency also depends on the device and on the internal oscillator frequency, which varies from 42.6 MHz to 100 MHz.

You can calculate the minimum and maximum time for any number of divisor based on the following formula:

Maximum time (n) = 2^(n-8) * t_{MAX}

Minimum time (n) = 2^n * t_{MIN}

where the range of n is from 0 to 8.

Table 9-3: Device EDCRC Detection Time in Arria V Devices

The following table lists the minimum and maximum time taken to calculate the CRC value:

- The minimum time is derived using the maximum clock frequency with a divisor of 0.
- The maximum time is derived using the minimum clock frequency with a divisor of 8.

Variant	Member Code	t_{MIN} (ms)	t_{MAX} (s)
Arria V GX	A1	13.74	8.80
	A3	13.74	8.80
	A5	21.42	13.71
	A7	21.42	13.71
	B1	30.45	19.49
	B3	30.45	19.49
	B5	40.70	26.05
	B7	40.70	26.05
Arria V GT	C3	13.74	8.80
	C7	21.42	13.71
	D3	30.45	19.49
	D7	40.70	26.05
Arria V GZ	E1	43.00	22.29
	E3	67.00	34.81
	E5	67.00	34.81
	E7	67.00	34.81
Arria V SX	B3	40.70	26.05
	B5	40.70	26.05
Arria V ST	D3	40.70	26.05
	D5	40.70	26.05

Using Error Detection Features in User Mode

This section describes the pin, registers, process flow, and procedures for error detection in user mode.

Enabling Error Detection

To enable user mode error detection in the Quartus II software, follow these steps:

1. On the Assignments menu, click **Device**.
2. In the Device dialog box, click **Device and Pin Options**.
3. In the **Category** list, click **Error Detection CRC**.
4. Turn on **Enable Error Detection CRC_ERROR pin**.
5. To set the CRC_ERROR pin as output open drain, turn on **Enable open drain on CRC_ERROR pin**. Turning off this option sets the CRC_ERROR pin as output.
6. In the **Divide error check frequency by** list, select a valid divisor.
7. Click OK.

CRC_ERROR Pin

Table 9-4: Pin Description

Pin Name	Pin Type	Description
CRC_ERROR	I/O or output/ output open-drain	An active-high signal, when driven high indicates that an error is detected in the CRAM bits. This pin is only used when you enable error detection in user mode. Otherwise, the pin is used as a user I/O pin. When using the WYSIWYG function, you can route the crcerror port from the WYSIWYG atom to the dedicated CRC_ERROR pin or any user I/O pin. To route the crcerror port to a user I/O pin, insert a D-type flipflop between them.

Error Detection Registers

This section describes the registers used in user mode.

Figure 9-2: Block Diagram for Error Detection in User Mode

The block diagram shows the registers and data flow in user mode.

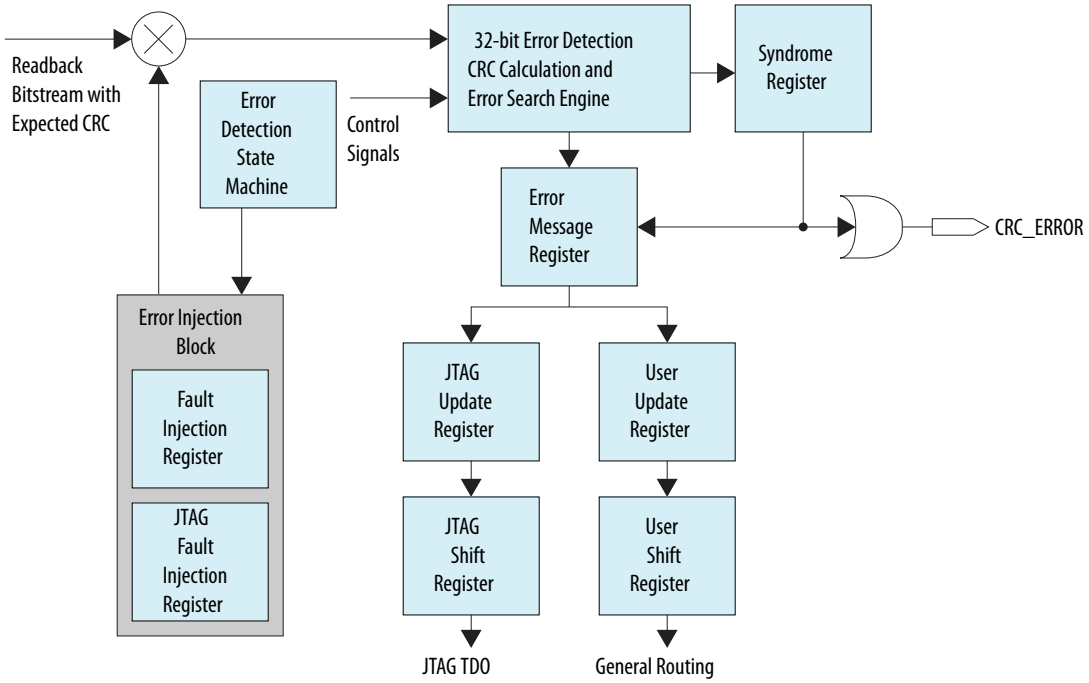


Table 9-5: Error Detection Registers

Name	Width (Bits)	Description
Syndrome register	32	Contains the 32-bit CRC signature calculated for the current frame. If the CRC value is 0, the CRC_ERROR pin is driven low to indicate no error. Otherwise, the pin is pulled high.
Error message register (EMR)	67	Contains error details for single-bit and double-adjacent errors. The error detection circuitry updates this register each time the circuitry detects an error. The Error Message Register Map figure shows the fields in this register and the Error Type in EMR table lists the possible error types.
JTAG update register	67	This register is automatically updated with the contents of the EMR one clock cycle after the content of this register is validated. The JTAG update register includes a clock enable, which must be asserted before its contents are written to the JTAG shift register. This requirement ensures that the JTAG update register is not overwritten when its contents are being read by the JTAG shift register.
JTAG shift register	67	This register allows you to access the contents of the JTAG update register via the JTAG interface using the SHIFT_EDERROR_REG JTAG instruction.

Name	Width (Bits)	Description
User update register	67	This register is automatically updated with the contents of the EMR one clock cycle after the contents of this register are validated. The user update register includes a clock enable, which must be asserted before its contents are written to the user shift register. This requirement ensures that the user update register is not overwritten when its contents are being read by the user shift register.
User shift register	67	This register allows user logic to access the contents of the user update register via the core interface.
JTAG fault injection register	46	You can use this register with the `EDERROR_INJECT JTAG` instruction to inject errors in the bitstream. The JTAG Fault Injection Register Map table lists the fields in this register.
Fault injection register	46	This register is updated with the contents of the JTAG fault injection register.

Figure 9-3: Error Message Register Map

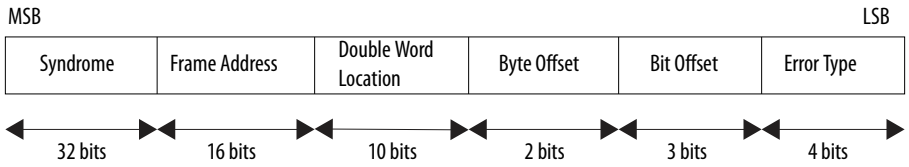

Table 9-6: Error Type in EMR

The following table lists the possible error types reported in the error type field in the EMR.

Error Type				Description
Bit 3	Bit 2	Bit 1	Bit 0	
0	0	0	0	No CRC error.
0	0	0	1	Location of a single-bit error is identified.
0	0	1	0	Location of a double-adjacent error is identified.
1	1	1	1	Error types other than single-bit and double-adjacent errors.

Table 9-7: JTAG Fault Injection Register Map

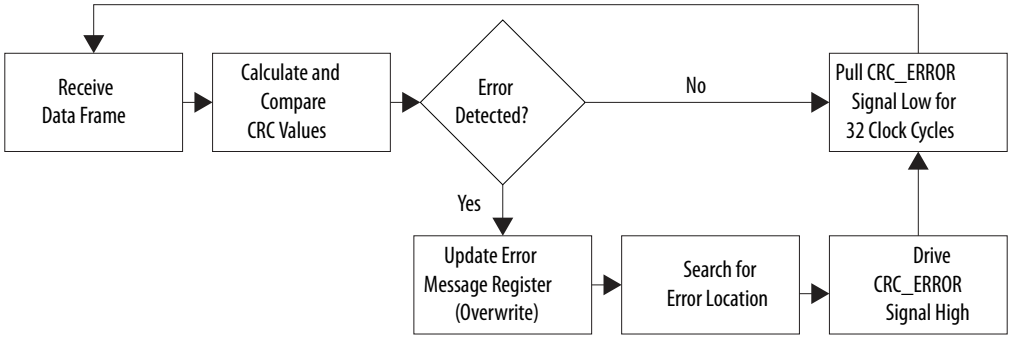
Field Name	Bit Range	Description
Error Byte Value	31:0	Contains the location of the bit error that corresponds to the error injection type to this field.
Byte Location	41:32	Contains the location of the injected error in the first data frame.

Field Name	Bit Range				Description
	45:42				Specifies the following error types.
	Bit 45	Bit 44	Bit 43	Bit 42	
Error Type	0	0	0	0	No error
	0	0	0	1	Single-bit error
	0	0	1	0	Double adjacent error

Error Detection Process

When enabled, the user mode error detection process activates automatically when the FPGA enters user mode. The process continues to run until the device is reset even when an error is detected in the current frame.

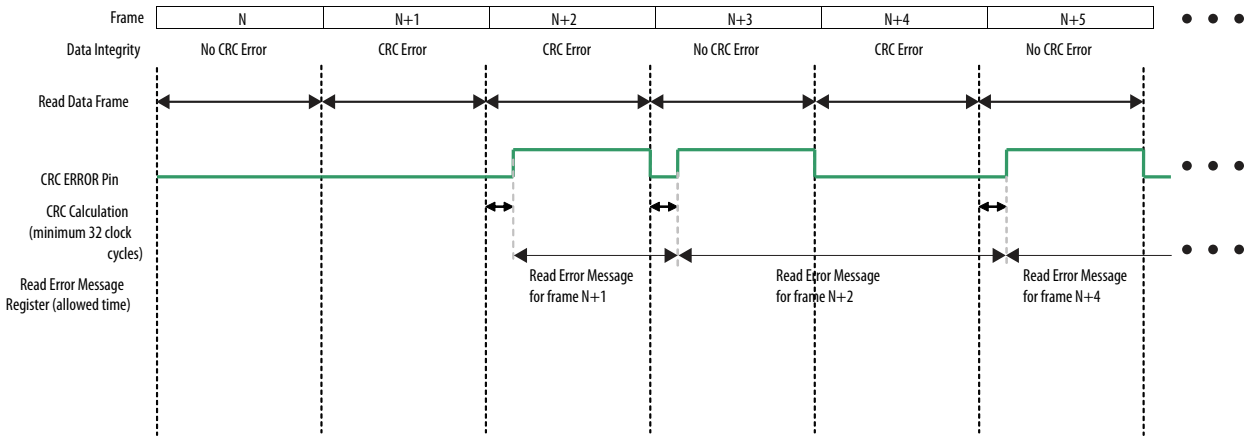
Figure 9-4: Error Detection Process Flow in User Mode



Timing

The CRC_ERROR pin is always driven low during CRC calculation for a minimum of 32 clock cycles. When an error occurs, the pin is driven high once the EMR is updated or 32 clock cycles have lapsed, whichever comes last. Therefore, you can start retrieving the contents of the EMR at the rising edge of the CRC_ERROR pin. The pin stays high until the current frame is read and then driven low again for a minimum of 32 clock cycles. To ensure information integrity, complete the read operation within one frame of the CRC verification. The following diagram shows the timing of these events.

Figure 9-5: Timing Requirements



Retrieving Error Information

You can retrieve the error information via the core interface or the JTAG interface using the `SHIFT_EDERROR_REG JTAG` instruction.

Recovering from CRC Errors

The system that hosts the FPGA must control device reconfiguration. To recover from a CRC error, drive the `nCONFIG` signal low. The system waits for a safe time before reconfiguring the device. When reconfiguration completes successfully, the FPGA operates as intended.

Related Information

  Provides more information about how to retrieve the error information.

Testing the Error Detection Block

You can inject errors into the configuration data to test the error detection block. This error injection methodology provides design verification and system fault tolerance characterization.

Testing via the JTAG Interface

You can intentionally inject single or double-adjacent errors into the configuration data using the `EDERROR_INJECT` JTAG instruction.

Table 9-8: EDERROR_INJECT instruction

JTAG Instruction	Instruction Code	Description
EDERROR_INJECT	00 0001 0101	Use this instruction to inject errors into the configuration data. This instruction controls the JTAG fault injection register, which contains the error you want to inject into the bitstream.

You can only inject errors into the first frame of the configuration data. However, you can monitor the error information at any time. Altera recommends that you reconfigure the FPGA after the test completes.

Automating the Testing Process

You can automate the testing process by creating a Jam™ file (**.jam**). Using this file, you can verify the CRC functionality in-system and on-the-fly without reconfiguring the device. You can then switch to the CRC circuitry to check for real errors caused by an SEU.

Document Revision History

Date	Version	Changes
January 2015	2015.01.23	Updated the description in the CRC Calculation Time section.
June 2014	2014.06.30	Updated the CRC Calculation Time section.
November 2013	2013.11.12	• Updated the CRC Calculation Time section to include a formula to calculate the minimum and maximum time. • Removed preliminary for the Minimum EMR Update Interval and CRC Calculation Time. • Removed related information for the Internal Scrubbing feature.
May 2013	2013.05.06	• Added link to the known document issues in the Knowledge Base. • Moved all links to the Related Information section of respective topics for easy reference.
November 2012	2012.11.19	• Added the following specifications for Arria V GZ—Minimum EMR update interval, error detection frequency, and CRC calculation time. • Updated the width of the JTAG fault injection and fault injection registers. • Reorganized content and updated template.

Date	Version	Changes
June 2012	2.0	• Added the "Basic Description", "Error Detection Features", "Types of Error Detection", "Error Detection Components", "Using the Error Detection Feature", and "Testing the Error Detection Block" sections. • Updated Table 9–4, Table 9–5, and Table 9–6. • Restructured the chapter.
November 2011	1.1	Restructured chapter.
May 2011	1.0	Initial release.

JTAG Boundary-Scan Testing in Arria V Devices 10

2015.01.23

AV-52010 Subscribe Send Feedback

This chapter describes the boundary-scan test (BST) features in Arria V devices.

Related Information

  Provides more information about JTAG configuration.
- **Arria V Device Handbook: Known Issues**
  Lists the planned updates to the *Arria V Device Handbook* chapters.

BST Operation Control

Arria V GX, GT, SX, and ST devices support IEEE Std. 1149.1 BST. Arria V GZ devices support IEEE Std. 1149.1 and IEEE Std. 1149.6 BST. You can perform BST on Arria V devices before, after, and during configuration.

IDCODE

The `IDCODE` is unique for each Arria V device. Use this code to identify the devices in a JTAG chain.

Table 10-1: IDCODE Information for Arria V Devices

Variant	Member Code	IDCODE (32 Bits)			
		Version (4 Bits)	Part Number (16 Bits)	Manufacture Identity (11 Bits)	LSB (1 Bit)
Arria V GX	A1	0000	0010 1010 0001 0001	000 0110 1110	1
	A3	0000	0010 1010 0000 0001	000 0110 1110	1

Supported JTAG Instruction

Table 10-2: JTAG Instructions Supported by Arria V Devices

JTAG Instruction	Instruction Code	Description
SAMPLE/PRELOAD	00 0000 0101	• Allows you to capture and examine a snapshot of signals at the device pins during normal device operation and permits an initial data pattern to be an output at the device pins. • Use this instruction to preload the test data into the update registers before loading the EXTEST instruction. • Used by the SignalTap™ II Embedded Logic Analyzer.
EXTEST	00 0000 1111	• Allows you to test the external circuit and board-level interconnects by forcing a test pattern at the output pins, and capturing the test results at the input pins. Forcing known logic high and low levels on output pins allows you to detect opens and shorts at the pins of any device in the scan chain. • The high-impedance state of EXTEST is overridden by bus hold and weak pull-up resistor features.

JTAG Instruction	Instruction Code	Description
BYPASS	11 1111 1111	Places the 1-bit bypass register between the TDI and TDO pins. During normal device operation, the 1-bit bypass register allows the BST data to pass synchronously through the selected devices to adjacent devices.
USERCODE	00 0000 0111	• Examines the user electronic signature (UES) within the devices along a JTAG chain. • Selects the 32-bit USERCODE register and places it between the TDI and TDO pins to allow serial shifting of USERCODE out of TDO. • The UES value is set to default value before configuration and is only user-defined after the device is configured.
IDCODE	00 0000 0110	• Identifies the devices in a JTAG chain. If you select IDCODE, the device identification register is loaded with the 32-bit vendor-defined identification code. • Selects the IDCODE register and places it between the TDI and TDO pins to allow serial shifting of IDCODE out of TDO. • IDCODE is the default instruction at power up and in the TAP RESET state. Without loading any instructions, you can go to the SHIFT_DR state and shift out the JTAG device ID.

JTAG Instruction	Instruction Code	Description
HIGHZ	00 0000 1011	• Sets all user I/O pins to an inactive drive state. • Places the 1-bit bypass register between the TDI and TDO pins. During normal operation, the 1-bit bypass register allows the BST data to pass synchronously through the selected devices to adjacent devices while tri-stating all I/O pins until a new JTAG instruction is executed. • If you are testing the device after configuration, the programmable weak pull-up resistor or the bus hold feature overrides the HIGHZ value at the pin.
CLAMP	00 0000 1010	• Places the 1-bit bypass register between the TDI and TDO pins. During normal operation, the 1-bit bypass register allows the BST data to pass synchronously through the selected devices to adjacent devices while holding the I/O pins to a state defined by the data in the boundary-scan register. • If you are testing the device after configuration, the programmable weak pull-up resistor or the bus hold feature overrides the CLAMP value at the pin. The CLAMP value is the value stored in the update register of the boundary-scan cell (BSC).
PULSE_NCONFIG	00 0000 0001	Emulates pulsing the nCONFIG pin low to trigger reconfiguration even though the physical pin is not affected.
CONFIG_IO	00 0000 1101	Allows I/O reconfiguration (after or during reconfigurations) through the JTAG ports using I/O configuration shift register (IOCSR) for JTAG testing. You can issue the CONFIG_IO instruction only after the nSTATUS pin goes high.

JTAG Instruction	Instruction Code	Description
LOCK	01 1111 0000	Put the device in JTAG secure mode. In this mode, only BYPASS, SAMPLE/PRELOAD, EXTEST, IDCODE, SHIFT_EDERROR_REG, and UNLOCK instructions are supported. This instruction can only be accessed through JTAG core access in user mode. It cannot be accessed through external JTAG pins in test or user mode.
UNLOCK	11 0011 0001	Release the device from the JTAG secure mode to enable access to all other JTAG instructions. This instruction can only be accessed through JTAG core access in user mode. It cannot be accessed through external JTAG pins in test or user mode.
KEY_CLR_VREG	00 0010 1001	Clears the volatile key.
KEY_VERIFY	00 0001 0011	Verifies the non-volatile key has been cleared.
EXTEST_PULSE (33)	00 1000 1111	Enables board-level connectivity checking between the transmitters and receivers that are AC coupled by generating three output transitions: • Driver drives data on the falling edge of TCK in the UPDATE_IR/DR state. • Driver drives inverted data on the falling edge of TCK after entering the RUN_TEST/IDLE state. • Driver drives data on the falling edge of TCK after leaving the RUN_TEST/IDLE state. The EXTEST_PULSE JTAG instruction is only supported in user mode for Arria V GZ devices.

(33) This instruction is only supported by Arria V GZ devices.

JTAG Instruction	Instruction Code	Description
EXTEST_TRAIN (33)	00 0100 1111	Behaves the same as the EXTEST_PULSE instruction except that the output continues to toggle on the TCK falling edge as long as the TAP controller is in the RUN_TEST/IDLE state. The EXTEST_TRAIN JTAG instruction is only supported in user mode for Arria V GZ devices.

Note: If the device is in a reset state and the nCONFIG or nSTATUS signal is low, the device IDCODE might not be read correctly. To read the device IDCODE correctly, you must issue the IDCODE JTAG instruction only when the nCONFIG and nSTATUS signals are high.

Note: If you use DC coupling on HSSI signals, execute the EXTEST instruction. If you use AC coupling on HSSI signals, execute the EXTEST_PULSE instruction. AC-coupled and DC-coupled HSSI are only supported in post-configuration mode.

Related Information

- **JTAG Secure Mode** on page 8-40
  Provides more information about PULSE_NCONFIG, CONFIG_IO, LOCK, and UNLOCK JTAG instructions.
- **Configuration, Design Security, and Remote System Upgrades in Arria V Devices**
  Provides more information about PULSE_NCONFIG, CONFIG_IO, LOCK, and UNLOCK JTAG instructions.

JTAG Secure Mode

If you enable the tamper-protection bit, the Arria V device is in JTAG secure mode after power up. In the JTAG secure mode, the JTAG pins support only the BYPASS, SAMPLE/PRELOAD, EXTEST, IDCODE, SHIFT_EDERROR_REG, and UNLOCK instructions. Issue the UNLOCK JTAG instruction to enable support for other JTAG instructions.

JTAG Private Instruction

Caution: Never invoke the following instruction codes. These instructions can damage and render the device unusable:

- 1100010000
- 0011001001
- 0000101011 (34)
- 1100010111
- 1100010011 (35)
- 1010100001
- 0101011110

(34) This JTAG private instruction is not applicable for Arria V GZ devices.
(35) This JTAG private instruction is only applicable for Arria V GZ devices.

I/O Voltage for JTAG Operation

The Arria V device operating in IEEE Std. 1149.1 BST mode uses four dedicated JTAG pins—TDI, TDO, TMS, and TCK. Arria V devices do not support the optional TRST pin.

The TCK pin has an internal weak pull-down resistor, while the TDI and TMS pins have internal weak pull-up resistors. The 3.3-, 3.0-, or 2.5-V V_{CCPD} supply of I/O bank 3A powers the TDO, TDI, TMS, and TCK pins. All user I/O pins are tri-stated during JTAG configuration.

The JTAG chain supports several different devices. Use the supported TDO and TDI voltage combinations listed in the following table if the JTAG chain contains devices that have different V_{CCIO} levels. The output voltage level of the TDO pin must meet the specification of the TDI pin it drives.

Note: Arria V GZ devices do not support 3.3-V V_{CCPD} supply.

Table 10-3: Supported TDO and TDI Voltage Combinations

The TDO output buffer for V_{CCPD} of 3.3 V or 3.0 V meets V_{OH} (MIN) of 2.4 V, and the TDO output buffer for V_{CCPD} of 2.5 V meets V_{OH} (MIN) of 2.0 V.

Device	TDI Input Buffer Power (V)	Arria V TDO V_{CCPD}		
		V_{CCPD} = 3.3 V	V_{CCPD} = 3.0 V	V_{CCPD} = 2.5 V
Arria V	V_{CCPD} = 3.3	Yes	Yes	Yes
	V_{CCPD} = 3.0	Yes	Yes	Yes
	V_{CCPD} = 2.5	Yes	Yes	Yes
Non- Arria V[36]	V_{CC} = 3.3	Yes	Yes	Yes
	V_{CC} = 2.5	Yes	Yes	Yes
	V_{CC} = 1.8	Yes	Yes	Yes
	V_{CC} = 1.5	Yes	Yes	Yes

Performing BST

You can issue BYPASS, IDCODE, and SAMPLE JTAG instructions before, after, or during configuration without having to interrupt configuration.

To issue other JTAG instructions, follow these guidelines:

- To perform testing before configuration, hold the nCONFIG pin low.
- To perform BST during configuration, issue CONFIG_IO JTAG instruction to interrupt configuration. While configuration is interrupted, you can issue other JTAG instructions to perform BST. After BST is completed, issue the PULSE_CONFIG JTAG instruction or pulse nCONFIG low to reconfigure the device.

The chip-wide reset (DEV_CLRn) and chip-wide output enable (DEV_OE) pins on Arria V devices do not affect JTAG boundary-scan or configuration operations. Toggling these pins does not disrupt BST operation (other than the expected BST behavior).

[36] The input buffer must be tolerant to the TDO V_{CCPD} voltage.

If you design a board for JTAG configuration of Arria V devices, consider the connections for the dedicated configuration pins.

Enabling and Disabling IEEE Std. 1149.1 BST Circuitry

The IEEE Std. 1149.1 BST circuitry is enabled after the Arria V device powers up. However for Arria V SoC FPGAs, you must power up both HPS and FPGA to perform BST.

To ensure that you do not inadvertently enable the IEEE Std. 1149.1 circuitry when it is not required, disable the circuitry permanently with pin connections as listed in the following table.

Table 10-4: Pin Connections to Permanently Disable the IEEE Std. 1149.1 Circuitry for Arria V Devices

JTAG Pins[37]	Connection for Disabling
TMS	V_{CCPD} supply of Bank 3A
TCK	GND
TDI	V_{CCPD} supply of Bank 3A
TDO	Leave open

[37] The JTAG pins are dedicated. Software option is not available to disable JTAG in Arria V devices.

Guidelines for IEEE Std. 1149.1 Boundary-Scan Testing

Consider the following guidelines when you perform BST with IEEE Std. 1149.1 devices:

- If the "10..." pattern does not shift out of the instruction register through the TDO pin during the first clock cycle of the SHIFT_IR state, the TAP controller did not reach the proper state. To solve this problem, try one of the following procedures:
  - Verify that the TAP controller has reached the SHIFT_IR state correctly. To advance the TAP controller to the SHIFT_IR state, return to the RESET state and send the 01100 code to the TMS pin.
  - Check the connections to the VCC, GND, JTAG, and dedicated configuration pins on the device.
- Perform a SAMPLE/PRELOAD test cycle before the first EXTEST test cycle to ensure that known data is present at the device pins when you enter EXTEST mode. If the OEJ update register contains 0, the data in the OUTJ update register is driven out. The state must be known and correct to avoid contention with other devices in the system.
- Do not perform EXTEST testing during in-circuit reconfiguration because EXTEST is not supported during in-circuit reconfiguration. To perform testing, wait for the configuration to complete or issue the CONFIG_IO instruction to interrupt configuration.
- After configuration, you cannot test any pins in a differential pin pair. To perform BST after configuration, edit and redefine the BSC group that correspond to these differential pin pairs as an internal cell.

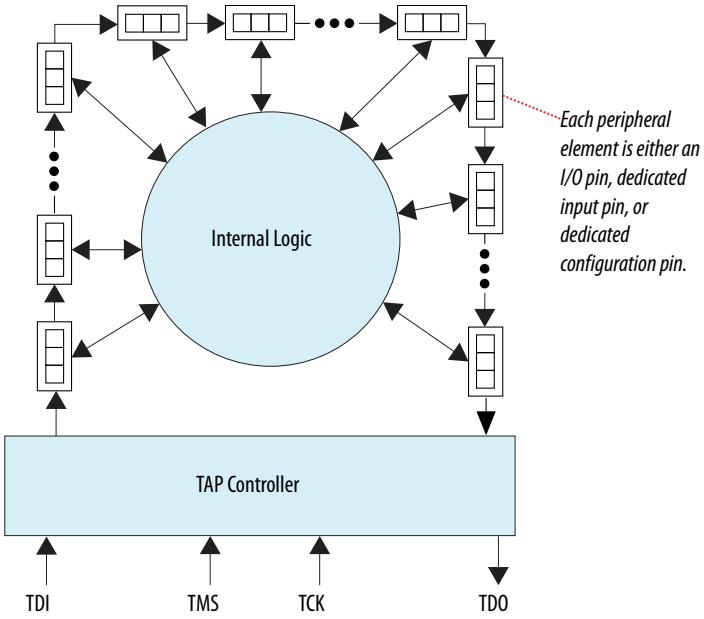
IEEE Std. 1149.1 Boundary-Scan Register

The boundary-scan register is a large serial shift register that uses the TDI pin as an input and the TDO pin as an output. The boundary-scan register consists of 3-bit peripheral elements that are associated with Arria V I/O pins. You can use the boundary-scan register to test external pin connections or to capture internal data.

Figure 10-1: Boundary-Scan Register

This figure shows how test data is serially shifted around the periphery of the IEEE Std. 1149.1 device.



Boundary-Scan Cells of an Arria V Device I/O Pin

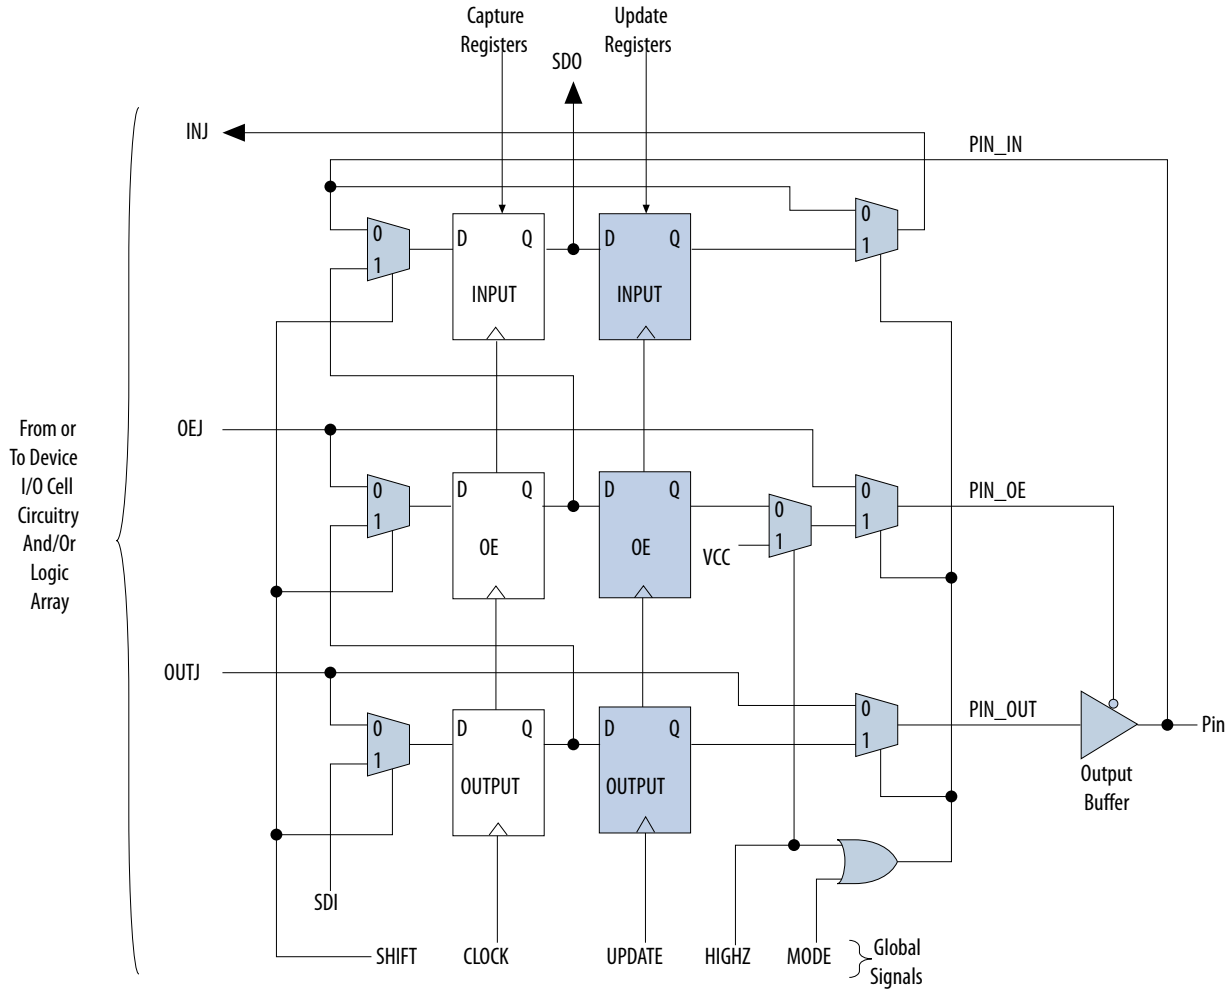
The Arria V device 3-bit BSC consists of the following registers:

- Capture registers—Connect to internal device data through the `OUTJ`, `OEJ`, and `PIN_IN` signals.
- Update registers—Connect to external data through the `PIN_OUT` and `PIN_OE` signals.

The TAP controller generates the global control signals for the IEEE Std. 1149.1 BST registers (`shift`, `clock`, and `update`) internally. A decode of the instruction register generates the `MODE` signal.

The data signal path for the boundary-scan register runs from the serial data in (`SDI`) signal to the serial data out (`SDO`) signal. The scan register begins at the `TDI` pin and ends at the `TDO` pin of the device.

Figure 10-2: User I/O BSC with IEEE Std. 1149.1 BST Circuitry for Arria V Devices



Note: TDI, TDO, TMS, and TCK pins, all VCC and GND pin types, and VREF pins do not have BSCs.

Table 10-5: Boundary-Scan Cell Descriptions for Arria V Devices

This table lists the capture and update register capabilities of all BSCs within Arria V devices.

Pin Type	Captures			Drives			Comments
	Output Capture Register	OE Capture Register	Input Capture Register	Output Update Register	OE Update Register	Input Update Register	
User I/O pins	OUTJ	OEJ	PIN_IN	PIN_OUT	PIN_OE	INJ	—
Dedicated clock input	0	1	PIN_IN	No Connect (N.C.)	N.C.	N.C.	PIN_IN drives to the clock network or logic array

Power Consumption

The total power consumption of an Arria V device consists of the following components:

- Static power—the power that the configured device consumes when powered up but no clocks are operating.
- Dynamic power— the additional power consumption of the device due to signal activity or toggling.

Dynamic Power Equation

Figure 11-1: Dynamic Power

The following equation shows how to calculate dynamic power where P is power, C is the load capacitance, and V is the supply voltage level.

$$P = \frac{1}{2} CV^2 \times frequency$$

The equation shows that power is design-dependent and is determined by the operating frequency of your design. Arria V devices minimize static and dynamic power using advanced process optimizations. This technology allows Arria V designs to meet specific performance requirements with the lowest possible power.

Programmable Power Technology

Arria V GZ devices offer the ability to configure portions of the core, called tiles, for high-speed or low-power mode of operation performed by the Quartus II software without user intervention. Setting a tile to high-speed or low-power mode is accomplished with on-chip circuitry and does not require extra power supplies brought into the Arria V GZ device. In a design compilation, the Quartus II software determines whether a tile should be in high-speed or low-power mode based on the timing constraints of the design.

Arria VGZ tiles consist of the following:

- Memory logic array block (MLAB)/ logic array block (LAB) pairs with routing to the pair
- MLAB/LAB pairs with routing to the pair and to adjacent digital signal processing (DSP)/ memory block routing
- TriMatrix memory blocks
- DSP blocks
- PCI Express® (PCIe®) hard IP
- Physical coding sublayer (PCS)

All blocks and routing associated with the tile share the same setting of either high-speed or low-power mode. By default, tiles that include DSP blocks or memory blocks are set to high-speed mode for optimum performance. Unused DSP blocks and memory blocks are set to low-power mode to minimize static power. Clock networks do not support programmable power technology.

With programmable power technology, faster speed grade FPGAs may require less power because there are fewer high-speed MLAB and LAB pairs, when compared with slower speed grade FPGAs. The slower speed grade device may have to use more high-speed MLAB and LAB pairs to meet performance requirements.

The Quartus II software sets unused device resources in the design to low-power mode to reduce the static power. It also sets the following resources to low-power mode when they are not used in the design:

- LABs and MLABs
- TriMatrix memory blocks
- DSP blocks

If a phase-locked loop (PLL) is instantiated in the design, you may assert the `areset` pin high to keep the PLL in low-power mode.

Altera recommends that you power down unused PCIe HIPs, per side, by connecting the PCIe HIP power to GND on the PCB for additional power savings. All of the HIPs on a side of the device must be unused to be powered down. For additional information refer to the pin connection guidelines.

Table 11-1: Programmable Power Capabilities for Arria V GZ Devices

This table lists the available Arria V GZ programmable power capabilities. Speed grade considerations can add to the permutations to give you flexibility in designing your system.

Feature	Programmable Power Technology
LAB	Yes
Routing	Yes
Memory Blocks	Fixed setting(42)
DSP Blocks	Fixed setting(42)
Clock Networks	No

Temperature Sensing Diode

The Arria V TSD uses the characteristics of a PN junction diode to determine die temperature. Knowing the junction temperature is crucial for thermal management. You can calculate junction temperature using ambient or case temperature, junction-to-ambient (ja) or junction-to-case (jc) thermal resistance, and device power consumption. Arria V devices monitor its die temperature with the internal TSD with built-in analog-to-digital converter (ADC) circuitry or the external TSD with an external temperature sensor. This allows you to control the air flow to the device.

All Arria V devices support internal TSD only except for Arria V GZ devices that support both internal and external TSDs.

(42) Tiles with DSP blocks and memory blocks that are used in the design are always set to high-speed mode. By default, unused DSP blocks and memory blocks are set to low-power mode.

Internal Temperature Sensing Diode

You can use the Arria V internal TSD in the following operations:

- Power-up mode—to read the die's temperature during configuration, enable the ALTTEMP_SENSE megafunction in your design.
- User mode—to read the die's temperature during user mode, assert the `clken` signal to the internal TSD circuitry.

Note: To reduce power consumption, disable the Arria V internal TSD when you are not using it.

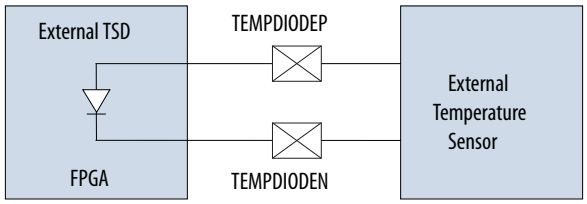
  Provides more information about the Arria V internal TSD specification.

External Temperature Sensing Diode

The Arria V GZ external TSD requires two pins for voltage reference. The following figure shows how to connect the external TSD with an external temperature sensor device, allowing external sensing of the Arria V GZ die temperature. For example, you can connect external temperature sensing devices, such as MAX1619, MAX1617A, MAX6627, and ADT7411 to the two external TSD pins for Arria V GZ device die temperature reading.

Figure 11-2: TSD External Pin Connections



The TSD is a very sensitive circuit that can be influenced by noise coupled from other traces on the board or within the device package itself, depending on your device usage. The interfacing signal from the Arria V GZ device to the external temperature sensor is based on millivolts (mV) of difference, as seen at the external TSD pins. Switching the I/O near the TSD pins can affect the temperature reading. Altera recommends taking temperature readings during periods of inactivity in the device or use the internal TSD with built-in ADC circuitry.

The following are board connection guidelines for the TSD external pin connections:

- The maximum trace lengths for the $TEMPDIODE_P$/$TEMPDIODE_N$ traces must be less than eight inches.
- Route both traces in parallel and place them close to each other with grounded guard tracks on each side.
- Altera recommends 10-mils width and space for both traces.
- Route traces through a minimum number of vias and crossunders to minimize the thermocouple effects.

- Ensure that the number of vias are the same on both traces.
- Ensure both traces are approximately the same length.
- Avoid coupling with toggling signals (for example, clocks and I/O) by having the GND plane between the diode traces and the high frequency signals.
- For high-frequency noise filtering, place an external capacitor (close to the external chip) between the $TEMPDIODE_P$/$TEMPDIODE_N$ trace. For Maxim devices, use an external capacitor between 2200 pF to 3300 pF.
- Place a 0.1 uF bypass capacitor close to the external device.
- You can use the internal TSD with built-in ADC circuitry and external TSD at the same time.
- If you only use internal ADC circuitry, the external TSD pins ($TEMPDIODE_P$/$TEMPDIODE_N$) can be connected to GND because the external TSD pins are not used.

For details about device specification and connection guidelines, refer to the external temperature sensor device datasheet from the device manufacturer.

Hot-Socketing Feature

Arria V devices support hot socketing—also known as hot plug-in or hot swap.

The hot-socketing circuitry monitors the following power supplies and banks:

- Arria V GX, GT, SX, and ST devices—V_{CCIO}, V_{CCPD}, V_{CC}, and V_{CCP} power supplies and all V_{CCIO} and V_{CCPD} banks.
- Arria V GZ devices—V_{CCIO}, V_{CCPD}, and V_{CC} power supplies and all V_{CCIO} and V_{CCPD} banks.

When powering up or powering down these power supplies, refer to the Power-Up Sequence section of this handbook.

During the hot-socketing operation, the I/O pin capacitance is less than 15 pF and the clock pin capacitance is less than 20 pF.

The hot-socketing capability removes some of the difficulty that designers face when using the Arria V devices on PCBs that contain a mixture of devices with different voltage requirements.

The hot-socketing capability in Arria V devices provides the following advantages:

- You can drive signals into the I/O, dedicated input, and dedicated clock pins before or during power up or power down without damaging the device. External input signals to the I/O pins of the unpowered device will not power the power supplies through internal paths within the device.
- The output buffers are tri-stated during system power up or power down. Because the Arria V device does not drive signals out before or during power up, the device does not affect the other operating buses.
- You can insert or remove an Arria V device from a powered-up system board without damaging or interfering with the system board's operation. This capability allows you to avoid sinking current through the device signal pins to the device power supply, which can create a direct connection to GND that causes power supply failures.
- During hot socketing, Arria V devices are immune to latch up that can occur when a device is hot-socketed into an active system.

Altera uses GND as a reference for hot-socketing and I/O buffer circuitry designs. To ensure proper operation, connect GND between boards before connecting the power supplies. This prevents GND on your board from being pulled up inadvertently by a path to power through other components on your board. A pulled up GND could otherwise cause an out-of-specification I/O voltage or over current condition in the Altera device.

  Provides details about the Arria V hot-socketing specifications.

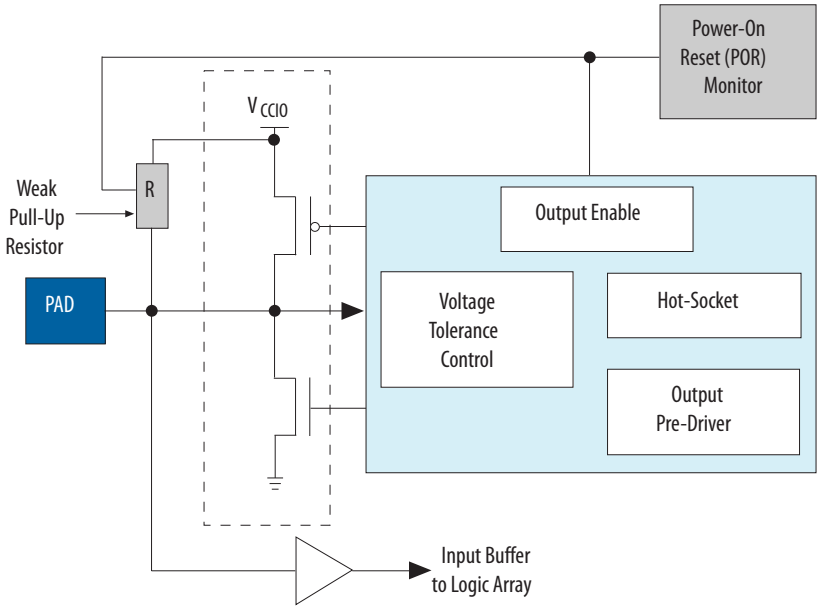
Hot-Socketing Implementation

The hot-socketing feature tri-state the output buffer during power up and power down of the power supplies. When these power supplies are below the threshold voltage, the hot-socketing circuitry generates an internal `HOTSCKT` signal.

Hot-socketing circuitry prevents excess I/O leakage during power up. When the voltage ramps up very slowly, I/O leakage is still relatively low, even after the release of the POR signal and configuration is complete.

Note: The output buffer cannot flip from the state set by the hot-socketing circuitry at very low voltage. To allow the `CONF_DONE` and `nSTATUS` pins to operate during configuration, the hot-socketing feature is not applied to these configuration pins. Therefore, these pins will drive out during power up and power down.

Figure 11-3: Hot-Socketing Circuitry for Arria V Devices



The POR circuitry monitors the voltage level of the power supplies and keeps the I/O pins tri-stated until the device is in user mode. The weak pull-up resistor (R) in the Arria V input/output element (IOE) is enabled during configuration download to keep the I/O pins from floating.

The 3.3-V tolerance control circuit allows the I/O pins to be driven by 3.3 V before the power supplies are powered and prevents the I/O pins from driving out before the device enters user mode.

Arria V GX, GT, SX, and ST Power-Up Sequence

Caution: To ensure minimum current consumption during power up, and to avoid functionality issue, follow the power-up sequence shown in the following figure. This power-up sequence is required for all Arria V GX and GT devices, except Arria V GX A5 and A7, and Arria V GT C7 devices. However, to ensure minimum current consumption during power up, Altera recommends that you also follow the power-up sequence for the Arria V GX A5 and A7, and Arria VGT C7 devices.

Note: If you plan to migrate your design from Arria V GX A5 and A7, and Arria V GT C7 devices to other Arria V devices, your design must adhere to the power-up sequence required for the other Arria V devices.

Figure 11-4: Power-Up Sequence Requirement for Arria V GX and GT Devices

Power up V_{CCBAT} at any time. Ramp up the power rails in each group to a minimum of 80% of their full rail before the next group starts. Power up V_{CCP}, V_{CCR_GXB}, V_{CCT_GXB}, and V_{CCL_GXB} together with V_{CC}.

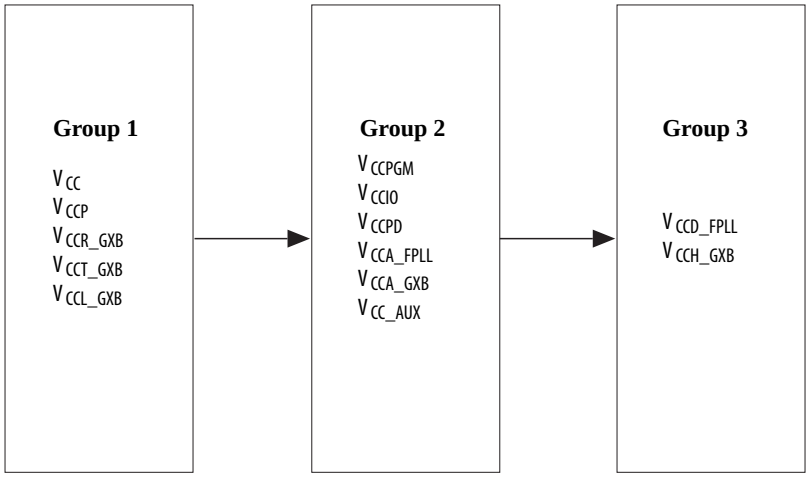


Figure 11-5: Power-Up Sequence Recommendation for Arria V SX and ST Devices

Power up the V_{ccbat} at any time. Ramp up the power rails in each group to a minimum of 80% of their recommended operating range before the next group starts.

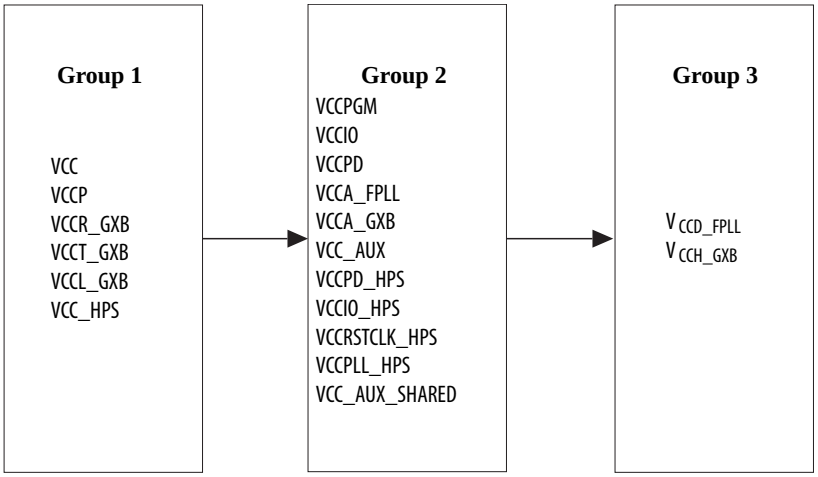

Table 11-2 lists the current transient that you may observe at the indicated power rails after powering up the Arria V device, and before configuration starts. These transients have a finite duration bounded by the time at which the device enters configuration mode. For Arria V SX and ST devices, you may observe the current transient in Table 11-2 after powering up the device, and before all the power supplies reach the recommended operating range.

Table 11-2: Maximum Power Supply Current Transient and Typical Duration

Power Rail	Maximum Power Supply Current Transient (mA)	Typical Duration (µs) [43]
V_{CCPD} [44], [45]	1250	50
V_{CCIO} [45], [46]	350	200
V_{CC_AUX} [47]	450	10
V_{CC} [47]	700	100
V_{CCPD_HPS} [48], [49], [50]	400	50
V_{CCIO_HPS} [48], [51], [50]	100	200
V_{CC_HPS} [47], [48]	420	100

For details about the minimum current requirements, refer to the PowerPlay Early Power Estimator (EPE), and compare to the information listed in **Table 11-2**. If the current transient exceeds the minimum current requirements in the PowerPlay EPE, you need to take the information into consideration for your power regulator design.

Related Information

PowerPlay Early Power Estimators (EPE) and Power Analyzer
Provides more information about the PowerPlay EPE support for Arria V devices.

Arria V GZ Power-Up Sequence

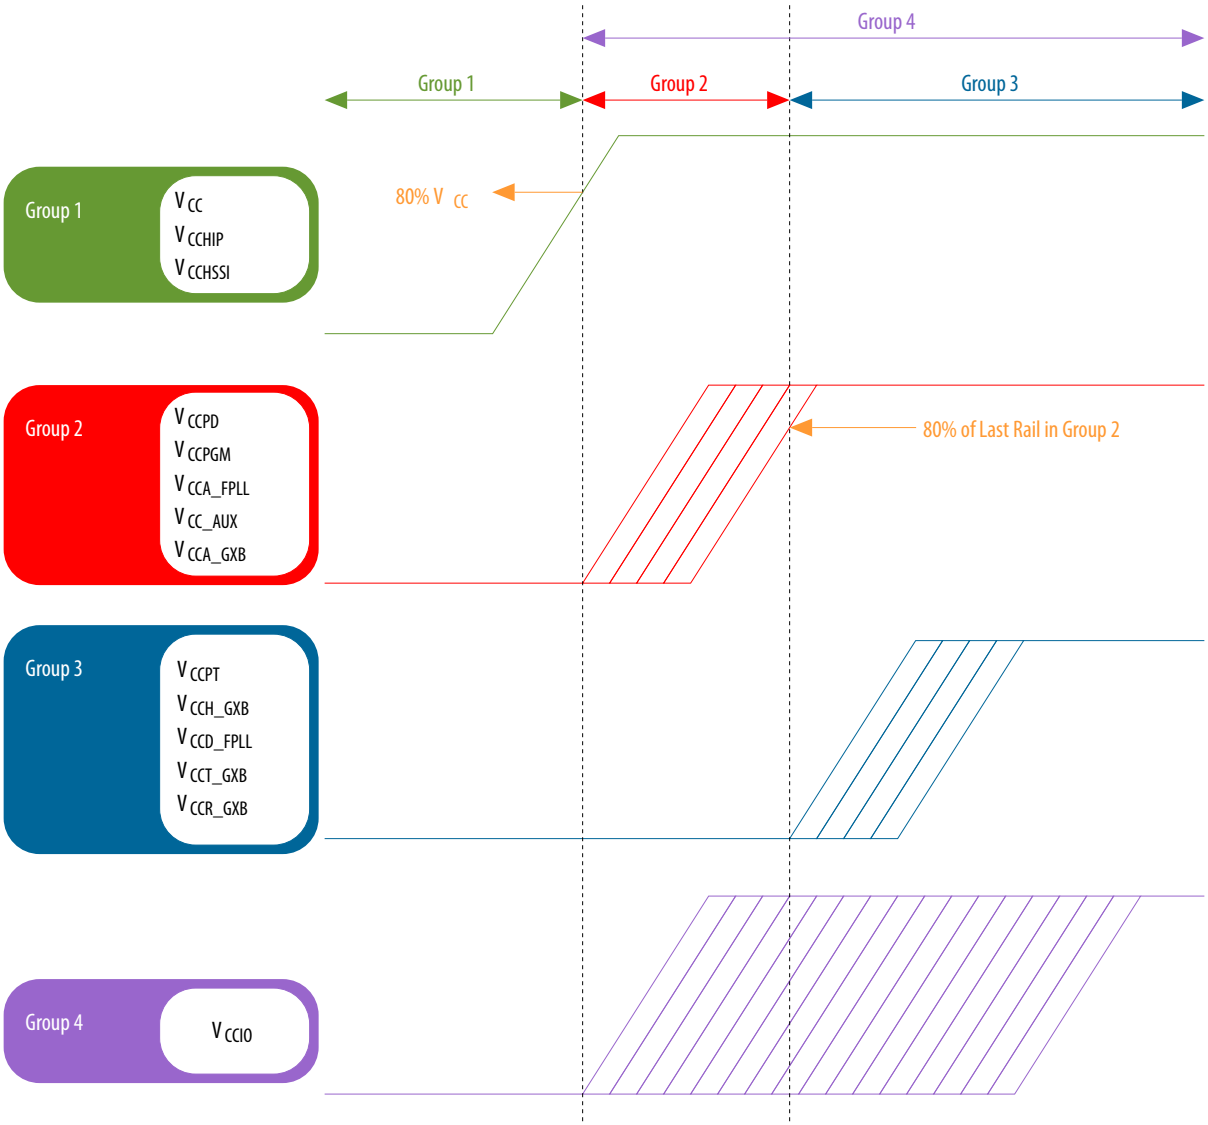
The Arria V GZ devices require a power-up sequence as shown in the following figure to prevent excessive inrush current. This power-up sequence is divided into four power groups. Group 1 contains the first power rails to ramp. The V_{CC}, V_{CCHIP}, and V_{CCHSSI} power rails in this group must ramp to a minimum of 80% of their full rail before any other power rails may start. Group 1 power rails can continue to ramp to full rail. The power rails in Group 2 and Group 4 can start to ramp in any order after Group 1 has reached its minimum 80% threshold. When the last power rail in Group 2 reaches 80% of its

(43) Only typical duration is provided as it may vary on the board design.
(44) You may observe the current transient at V_{CCPD} only when you do not follow the recommended power-up sequence. To avoid the current transient at V_{CCPD}, follow the recommended power-up sequence.
(45) The maximum current for V_{CCIO} and V_{CCPD} applies to all voltage levels supported by the Arria V device.
(46) You may observe the current transient at V_{CCIO} if you power up V_{CCIO} before V_{CCPD}. To avoid the current transient at V_{CCIO}, follow the recommended power-up sequence by powering up V_{CCIO} and V_{CCPD} together.
(47) You may observe the current transient at V_{CC_AUX}, V_{CC} and V_{CC_HPS} with any power-up sequence.
(48) These power rails are only available on Arria V SX and ST devices.
(49) You may observe the current transient at V_{CCPD_HPS} only when you do not follow the recommended power-up sequence. To avoid the current transient at V_{CCPD_HPS}, follow the recommended power-up sequence.
(50) The maximum current for V_{CCIO_HPS} and V_{CCPD_HPS} applies to all voltage levels supported by the Arria V device.
(51) You may observe the current transient at V_{CCIO_HPS} if you power up V_{CCIO_HPS} before V_{CCPD_HPS}. To avoid the current transient at V_{CCIO_HPS}, follow the recommended power-up sequence by powering up V_{CCIO_HPS} and V_{CCPD_HPS} together.

full rail, the remaining power rails in Group 3 may start their ramp. During this time, Group 2 power rails may continue to ramp to full rail. Power rails in Group 3 may ramp in any order. All power rails must ramp monotonically. The complete power-up sequence must meet either the standard or fast POR delay time, depending on the POR delay setting that is used.

Figure 11-6: Power-Up Sequence Requirement for Arria V GZ Devices

Power up V_{CCBAT} at any time. If V_{CC}, V_{CCR_GXB}, and V_{CCT_GXB} have the same voltage level, they can be powered by the same regulator in Group 1 and ramp simultaneously.



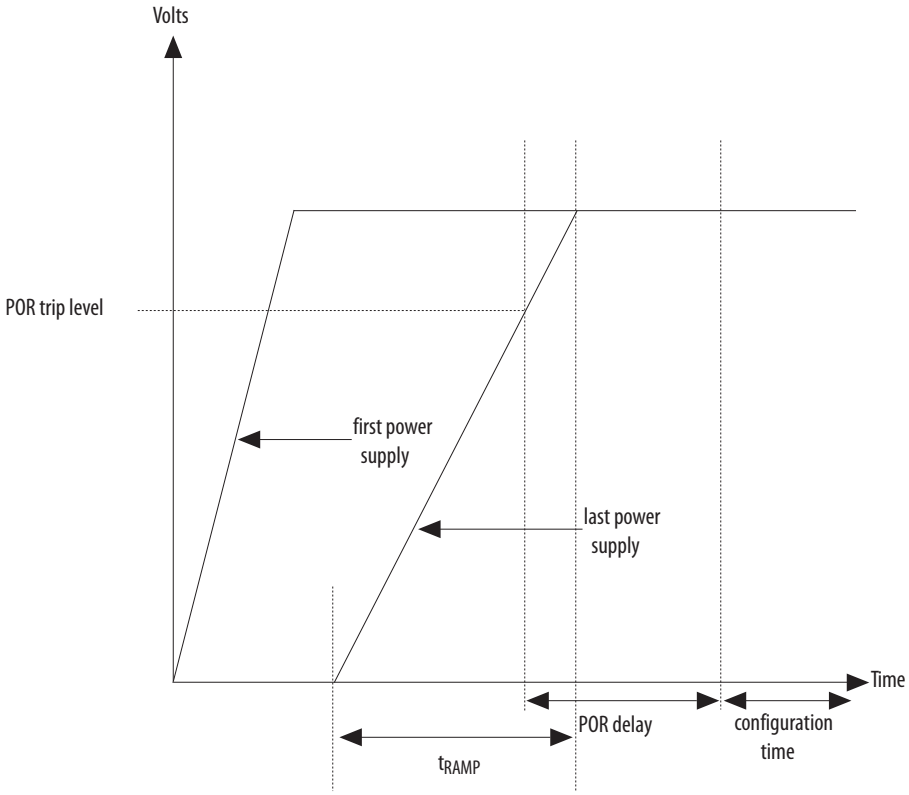
Arria V GZ devices may power down all power rails simultaneously. However, all rails must reach 0 V within 100 ms from the start of power-down.

Power-On Reset Circuitry

The POR circuitry keeps the Arria V device in the reset state until the power supply outputs are within the recommended operating range.

A POR event occurs when you power up the Arria V device until the power supplies reach the recommended operating range within the maximum power supply ramp time, t_{RAMP}. If t_{RAMP} is not met, the Arria V device I/O pins and programming registers remain tri-stated, during which device configuration could fail.

Figure 11-7: Relationship Between t_{RAMP} and POR Delay



The Arria V POR circuitry uses an individual detecting circuitry to monitor each of the configuration-related power supplies independently. The main POR circuitry is gated by the outputs of all the individual detectors. The main POR signal is asserted when the power starts to ramp up. This signal is released after the last ramp-up power reaches the POR trip level during power up.

In user mode, the main POR signal is asserted when any of the monitored power goes below its POR trip level. Asserting the POR signal forces the device into the reset state.

The POR circuitry checks the functionality of the I/O level shifters powered by the V_{CCPD} and V_{CCPGM} power supplies during power-up mode. The main POR circuitry waits for all the individual POR circuitries to release the POR signal before allowing the control block to start programming the device.

AV53001 Subscribe Send Feedback

Describes the Arria® V transceiver architecture, channels, and transmitter and receiver channel datapaths.

Altera® 28-nm Arria V FPGAs provide integrated transceivers with the lowest power requirement at 12.5-, 10-, and 6-Gigabits per second (Gbps). These transceivers comply with a wide range of protocols and data rate standards.

Table 1-1: Arria V Variants

Variants	Hard Processor System (HPS)	Up to 6.5536 Gbps	Beyond 6.5536 Gbps
GX	N/A	Backplane	N/A
GT	N/A	Backplane	N/A
GZ	N/A	Backplane	Up to 12.5 Gbps with backplane support
SX	Yes	Backplane	N/A
ST	Yes	Backplane	N/A

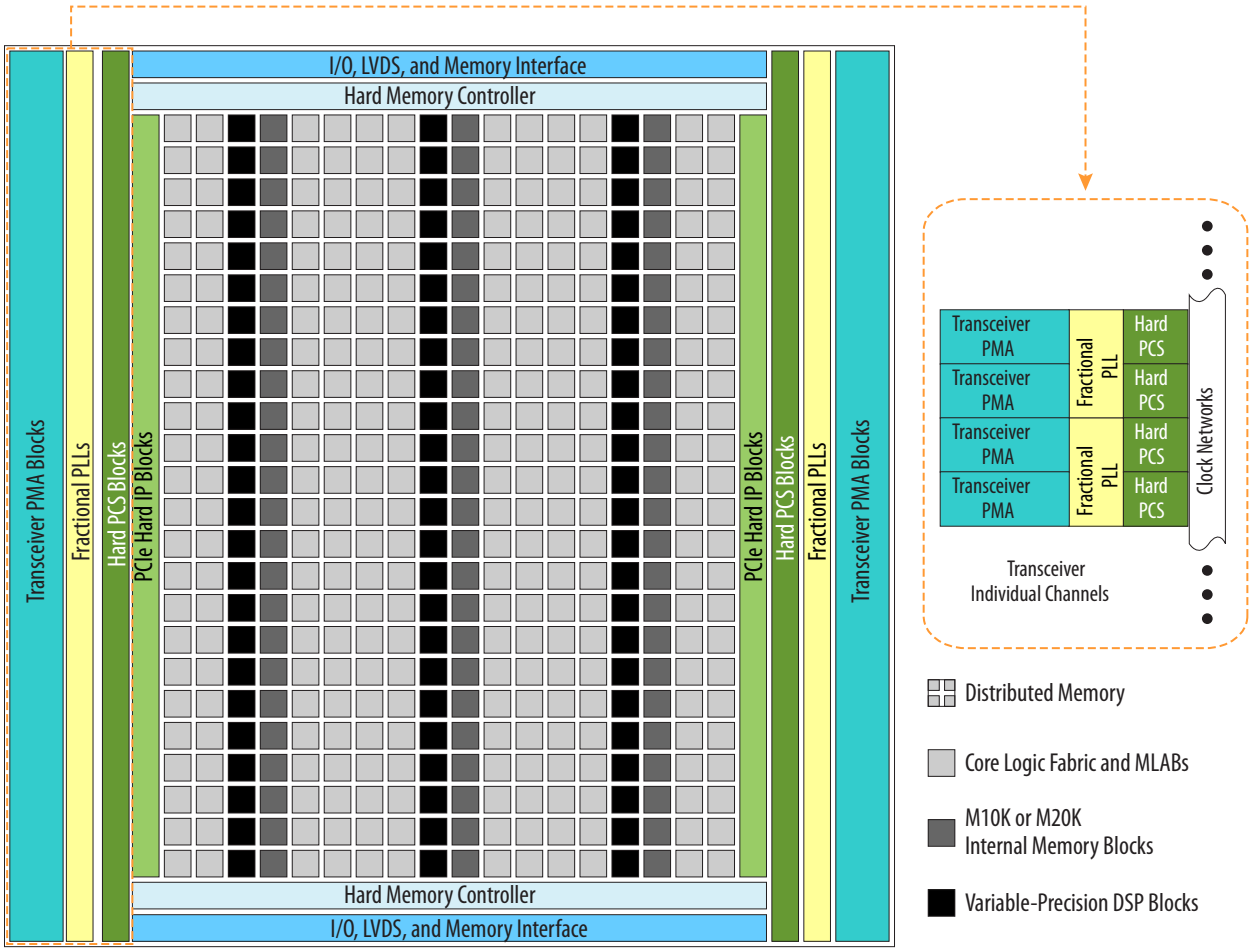
Arria V Device Handbook: Known Issues
Lists the planned updates to the *Arria V Device Handbook* chapters.

Architecture Overview

Figure 1-1: Basic Layout of Transceivers in Arria V Devices



Notes:
1. This figure represents one variant of an Arria V device. Other variants may have transceivers and PCI Express (PCIe) hard IP only on the left side of the device.
2. This figure is a graphical representation of a top view of the silicon die, which corresponds to a reverse view for flip chip packages.

The Arria V hard IP for PCIe implements the PCIe protocol stack including the following layers:

- Physical interface/media access control (PHY/MAC) layer
- Data link layer
- Transaction layer

The embedded hard IP saves significant FPGA resources, reduces design risk, and reduces the time required to achieve timing closure. The hard IP complies with the PCI Express Base Specification 1.1, 2.0, and 3.0 for Gen1, Gen2, and Gen3 signaling data rates, respectively. In addition, the Arria V GZ variant supports PCI Express Base Specification 3.0 for Gen3 signaling datarates.

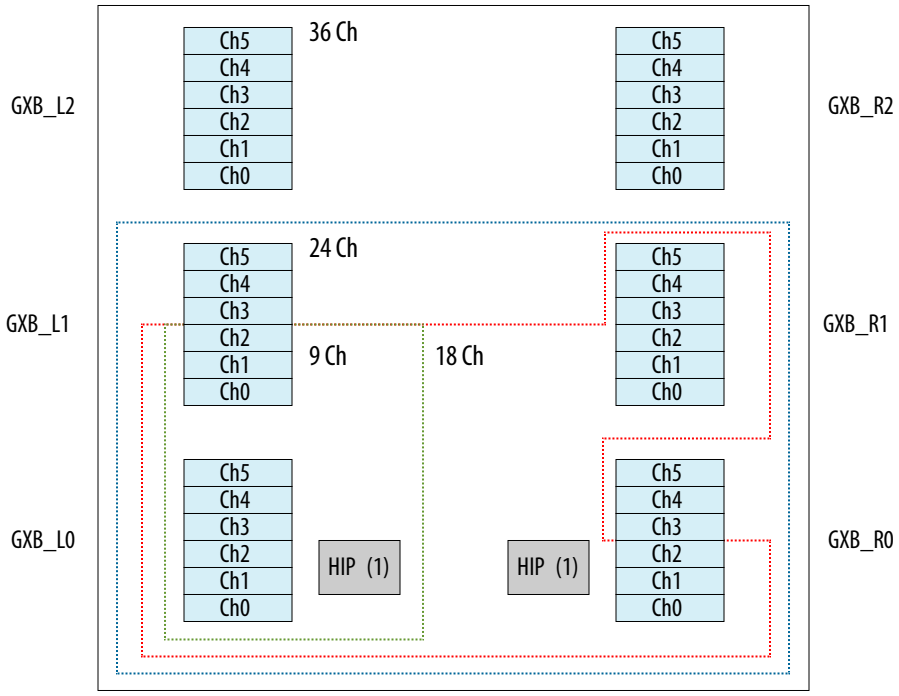
Related Information

For more information about the PCIe hard IP block architecture, see the Arria V Hard IP for PCI Express User Guide.

Transceiver Banks

The columns of Arria V transceivers are categorized in banks of six channels. The transceiver bank boundaries are important for clocking resources, bonding channels, and fitting. In some package variations, some transceiver banks are reduced to three channels. In the Arria V GX/GT/SX/ST, there are fundamentally two types of transceiver channels; 6-Gbps and 10-Gbps. By contrast, every Arria V GZ transceiver channel supports operation up to 12.5 Gbps data rates.

Figure 1-2: Transceiver Bank and PCIe Hard IP Location for GX Devices (1), (2)

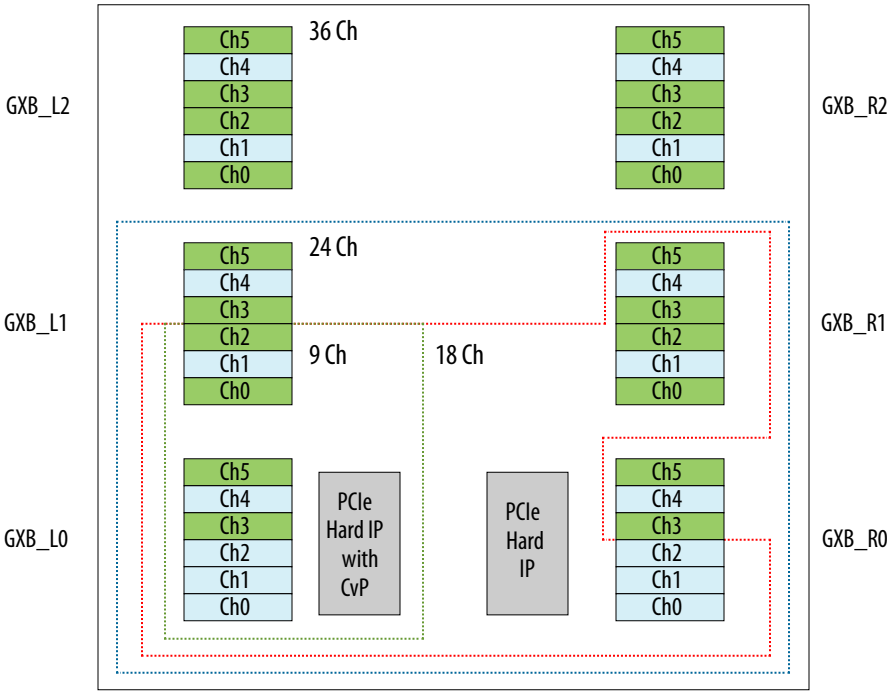


Notes:
1. PCIe HIP availability varies with device variants.
2. Blue blocks are 6 Gbps channels.

Table 1-2: Hard IP and Channel Resources in GX Variants

GX Variants	Left Hard IP	Right Hard IP	Total Channels
Base	None	None	9
Mainstream	1	None	9, 18
Extended Feature	1	1	24, 36

Figure 1-3: Transceiver Bank and PCIe Hard IP Location for GT Devices

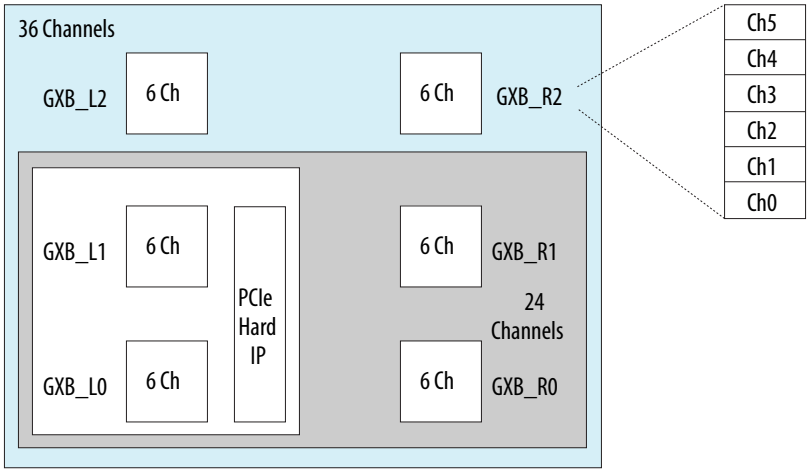


Notes:
1. Green blocks are 10-Gbps channels.
2. Blue blocks are 6-Gbps channels.

Table 1-3: Hard IP and Channel Resources in GT Variants

GT Variants	Left Hard IP	Right Hard IP	Total Channels
Mainstream	1	None	9, 18
Extended Feature	1	1	24, 36

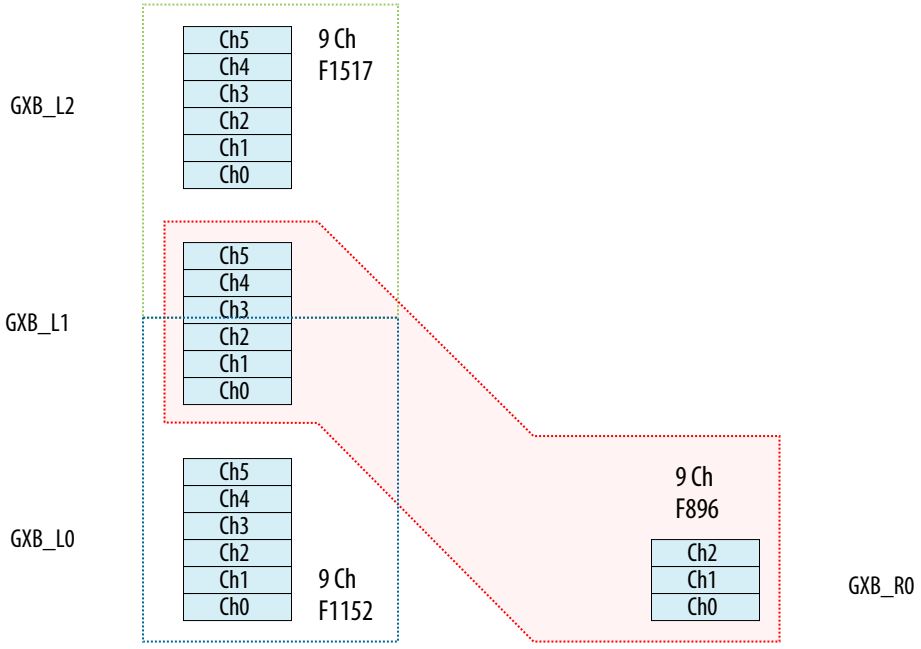
Figure 1-4: Transceiver Bank and PCIe Hard IP Location for GZ Devices



Notes:
1. 12-channel devices use banks L0 and L1.
2. All channels capable of backplane support up to 12.5 Gbps.

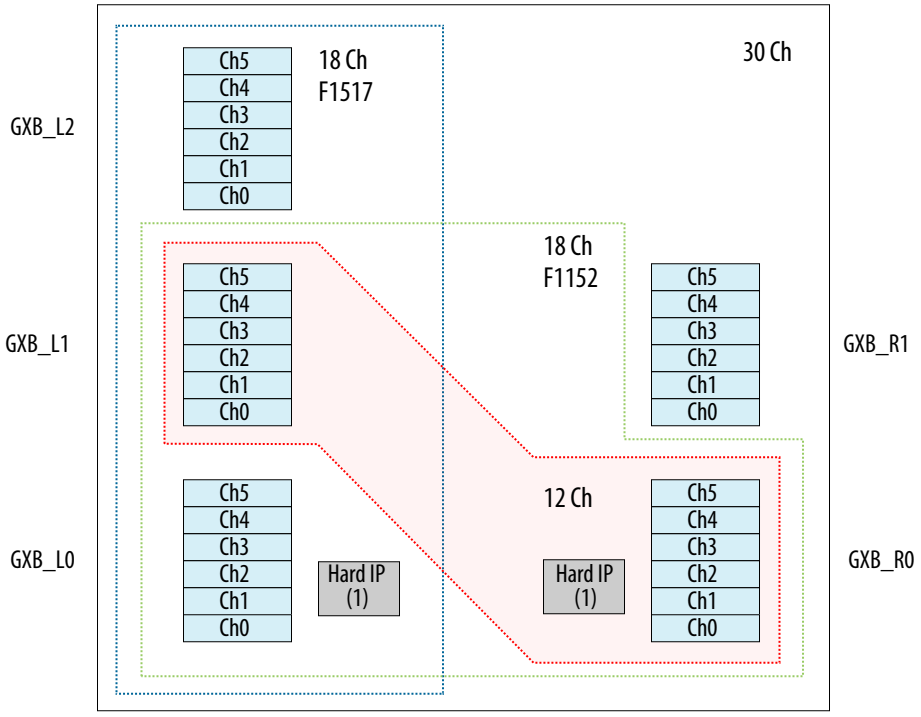
Figure 1-5: Transceiver Bank Location for SX Devices (9 channels)

SX devices with 9 channels do not have PCIe Hard IP blocks.



Note: Blue blocks are 6 Gbps channels.

Figure 1-6: Transceiver Bank and PCIe Hard IP Location for SX Devices (12,18, 30 channels) (1)

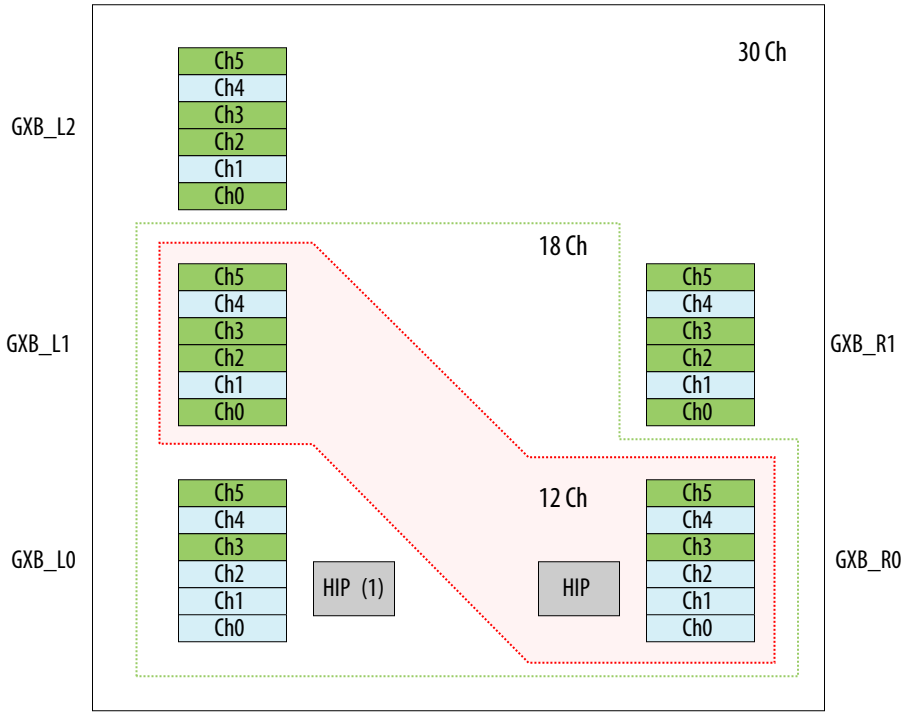


Notes:
1. PCIe Hard IP availability varies with device variants.
2. Blue blocks are 6 Gbps channels.

Table 1-4: Hard IP and Channel Resources in SX Variants

SX Variants	Left Hard IP	Right Hard IP	Total Channels
Mainstream	None	1	12
	1	None	18 (F1517 package)
Extended Feature	1	1	18 (F1152 package)
	1	1	30

Figure 1-7: Transceiver Bank and PCIe Hard IP Location for ST Devices(1), (2), (3)



Notes:
1. PCIe HIP availability varies with device variants.
2. Green blocks are 10-Gbps channels.
3. Blue blocks are 6-Gbps channels. With the exception of Ch0 to Ch2 in GXB_L0 and GXB_R0, the 6-Gbps channels can be used for TX-only or RX-only 10-Gbps channels.

Table 1-5: Hard IP and Channel Resources in ST Variants

ST Variants	Left Hard IP	Right Hard IP	Total Channels
Mainstream	None	1	12
Extended Feature	1	1	18
	1	1	30

Table 1-6: Usage Restrictions on Specific Channels Across Device Variants

Device Variants	Channel Location	Usage Restriction
GX, SX	Ch1, Ch2 of GXB_L0(1) Ch1, Ch2 of GXB_R0(1)	No support for PCS with phase compensation FIFO in registered mode (for example, CPRI or deterministic latency)

(1) The PMA clock of Channel 1 and Channel 2 of GBX_L0 and GXB_R0 cannot be routed out of the FPGA fabric for Arria V GX, GT, ST, and SX devices.

Device Variants	Channel Location	Usage Restriction
ST, GT	Ch1, Ch2 of GXB_L0 and GXB_R0(1)	No support for PCS with phase compensation FIFO in registered mode (for example, CPRI or deterministic latency)
ST	Ch0, Ch1, Ch2 of GXB_L0 and GXB_R0	No PMA Direct Support
GT	Ch0, Ch1, Ch2 of GXB_L0 and GXB_R0(1)	No PMA Direct Support

10-Gbps Support Capability in GT and ST Devices

Arria V GT/ST devices support up to four full duplex 10-Gbps channels in each transceiver bank. The bottom transceiver banks, and transceiver banks with only three transceiver channels, support up to two full duplex 10-Gbps channels.

Enhanced Small Form-Factor Pluggable (SFP+) Interface

Arria V GT devices are compliant to SFF 8431 with considerations to the number of channel requirements and board designs.Contact your local Altera sales representative for details.

10GBASE-KR Support

For 10GBASE-KR support, please contact Altera.

9.8 Gbps CPRI Application

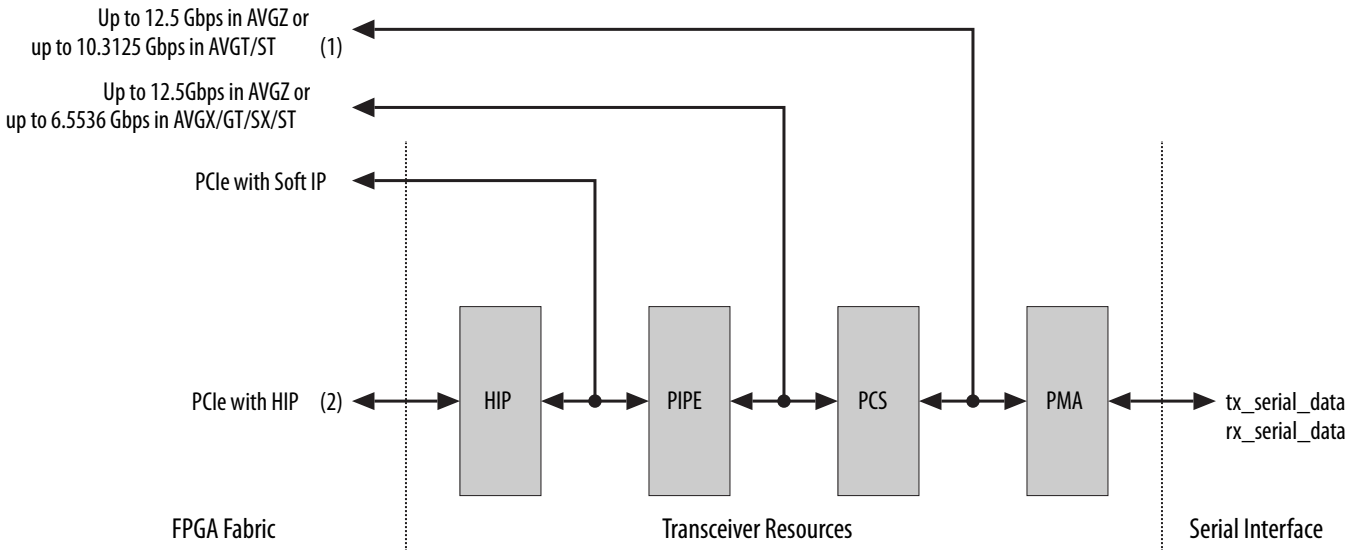
For 9.8 Gbps CPRI support, please contact Altera.

Transceiver Channel Architecture

The Arria V transceivers are comprised of a transmitter and receiver that can operate individually or simultaneously—providing a full-duplex physical layer implementation for high-speed serial interfacing. Each transmitter and receiver are divided into two blocks: PMA and PCS. The PMA block connects the FPGA to the channel, generates the required clocks, and converts the data from parallel to serial or serial to parallel. The PCS block performs digital processing logic between the PMA and the FPGA core.

Multiply the interface speed together with the serialization factor to determine the maximum supported data rate for any given transceiver configuration. For example, the Arria V GT supports a maximum interface speed of 161 MHz in PMA direct mode. To calculate the maximum supported data rate for a serialization factor of 20 in PMA direct mode, multiply 161 x 20 = 3220 Mbps.

Figure 1-8: Full Duplex Channel Interface Architecture



Notes:
1. 10-Gbps channel is available in GT and ST variants.
2. See the Related Information for specific channels that support interfaces with the HIP.
3. GX and GT can support up to 6.5536 Gbps.
4. GZ can support up to 12.5 Gbps.

Table 1-7: Architecture Differences Between 6- and 10-Gbps Arria V GT/ST Channels and Arria V GZ Channels

Architecture Differences	6-Gbps Channel	10-Gbps Channel[2]	Arria V GZ Channel
Transmitter PCS Capability	Up to 6.5536 Gbps	Up to 6.5536 Gbps	Up to 12.5 Gbps
Receiver PCS Capability	Up to 6.5536 Gbps	Up to 6.5536 Gbps [3]	Up to 12.5 Gbps
Transmitter/Receiver PMA Capability	Up to 6.5536 Gbps	Up to 10.3125 Gbps	Up to 12.5 Gbps
PMA Direct (PMA-Fabric Interface)	Not supported	Supported	Supported
Serialization Factor	8, 10, 16, 20	8, 10, 16, 20, 64, 80	8, 10, 16, 20, 32, 40, 64, 80

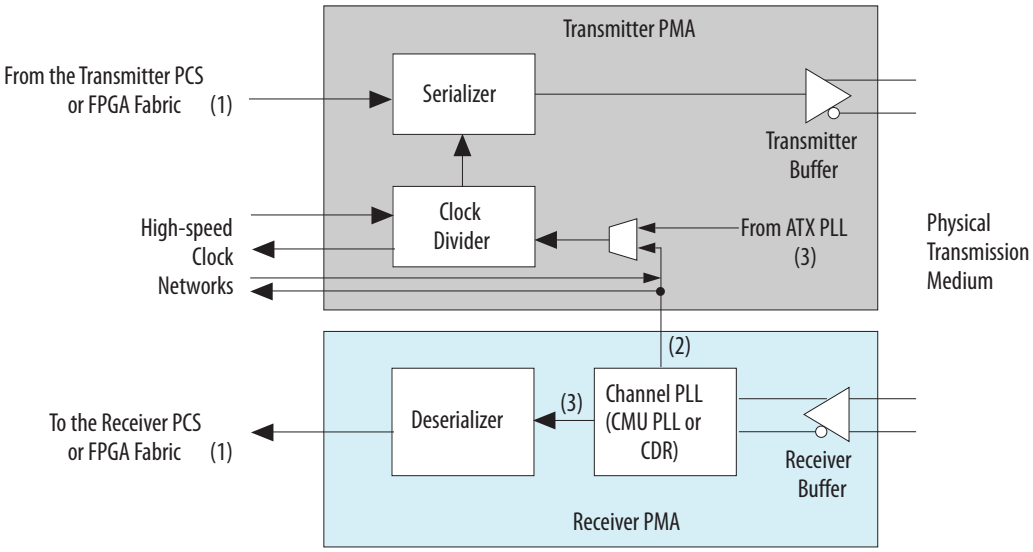
- **For Transceiver-FPGA interface speed specifications, refer to the Arria V Device Datasheet.**

[2] 10-Gbps channel is only available in GT and ST variants.
[3] Arria V GT/ST devices cannot use the PCS when running at 10 Gbps.

PMA Architecture

The PMA includes the transmitter and receiver datapaths, CMU PLL (configured from the channel PLL), the ATX PLL, and the clock divider. The analog circuitry and differential on-chip termination (OCT) in the PMA requires the calibration block to compensate for process, voltage, and temperature variations (PVT).

Figure 1-9: Transceiver Channel PMA for Arria V Devices



Notes:
1. The channel PLL provides the serial clock when configured as a CMU PLL.
2. The channel PLL recovers the clock and serial data stream when configured as a CDR.
3. ATX PLL available only in GZ devices.

Transmitter PMA Datapath

Table 1-8: Functional Blocks in the Transmitter PMA Datapath

Block	Functionality
Serializer	• Converts the incoming low-speed parallel data from the transmitter PCS to high-speed serial data and sends the data LSB first to the transmitter buffer. • Supports the optional polarity inversion and bit reversal features. • Supports 8, 10, 16, and 20-bit serialization factors in Arria V GX, SX, GT, ST, and GZ devices. • Additionally supports 64 and 80-bit serialization factors for 10-Gbps transceiver channels in Arria V ST and GT devices. • Additionally supports 32, 40, 64, and 80-bit serialization factors in Arria V GZ devices.

Block	Functionality
Transmitter Buffer	• The 1.4-V (Arria V GZ Only) and 1.5-V pseudo current mode logic (PCML) output buffer conditions the high-speed serial data for transmission into the physical medium. Arria GZ supports 1.4 and 1.5V PCML. • Supports the following features: • Programmable differential output voltage (VOD) • Programmable pre-emphasis • Programmable V_{CM} current strength • Programmable slew rate • On-chip biasing for common-mode voltage (TX V_{CM}) • Differential OCT (85, 100, 120 and 150 Ω) • Transmitter output tristate • Receiver detect (for the PCIe receiver detection function)

Serializer

The serializer provides parallel-to-serial data conversion and sends the data LSB first from the transmitter physical coding sublayer (PCS) to the transmitter buffer. Additionally, the serializer provides the polarity inversion and bit reversal features.

Polarity Inversion

The positive and negative signals of a serial differential link might accidentally be swapped during board layout.

The polarity inversion feature of the transmitter corrects this error without requiring a board respin or major updates to the logic in the FPGA fabric. The polarity inversion feature inverts the polarity of every bit at the input to the serializer, which has the same effect as swapping the positive and negative signals of the serial differential link.

Polarity inversion is controlled dynamically with the `tx_invpolarity` register. When you enable the polarity inversion feature, it may cause initial disparity errors at the receiver with 8B/10B-coded data. The downstream system at the receiver must be able to tolerate these disparity errors.

Caution: Enabling polarity inversion midway through a serialized word corrupts the word.

Bit Reversal

You can reverse the transmission bit order to achieve MSB-to-LSB ordering using the bit reversal feature at the transmitter.

Table 1-9: Bit Reversal Feature

	Transmission Bit Order	
Bit Reversal Option	8- or 10-bit Serialization Factor	16- or 20-bit Serialization Factor
Disabled (default)	LSB to MSB	LSB to MSB

Bit Reversal Option	Transmission Bit Order	
	8- or 10-bit Serialization Factor	16- or 20-bit Serialization Factor
Enabled	MSB to LSB For example: 8-bit—`D[7:0]` rewired to `D[0:7]` 10-bit—`D[9:0]` rewired to `D[0:9]`	MSB to LSB For example: 16-bit—`D[15:0]` rewired to `D[0:15]` 20-bit—`D[19:0]` rewired to `D[0:19]`

Transmitter Buffer

The transmitter buffer includes additional circuitry to improve signal integrity, such as the programmable differential output voltage (V_{OD}), programmable three-tap pre-emphasis circuitry, internal termination circuitry, and PCIe receiver detect capability to support a PCIe configuration.

Modifying programmable values within transmitter output buffers can be performed by a single reconfiguration controller for the entire FPGA, or multiple reconfiguration controllers if desired. Within each transceiver bank a maximum of two reconfiguration controllers is allowed; one for the three-transceiver triplet in the upper-half of the bank, and one for the lower-half. This is due to a single slave interface to all PLLs and PMAs within each triplet. Therefore, many triplets can be connected to a single reconfiguration controller, but only one reconfiguration controller can be connected to the three transceivers within any triplet.

Note: A maximum of one reconfiguration controller is allowed per transceiver bank upper-half or lower-half triplet.

Note: The Arria V GT transmitter buffer has only one tap for the pre-emphasis.

Figure 1-10: Transmitter Buffer in Arria V Devices

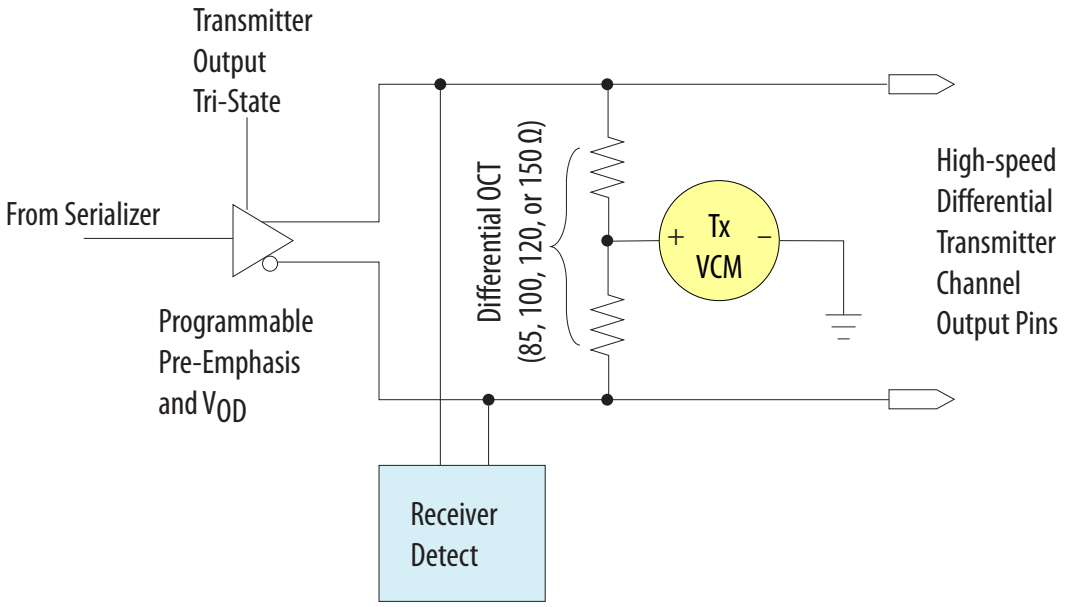


Table 1-10: Description of the Transmitter Buffer Features

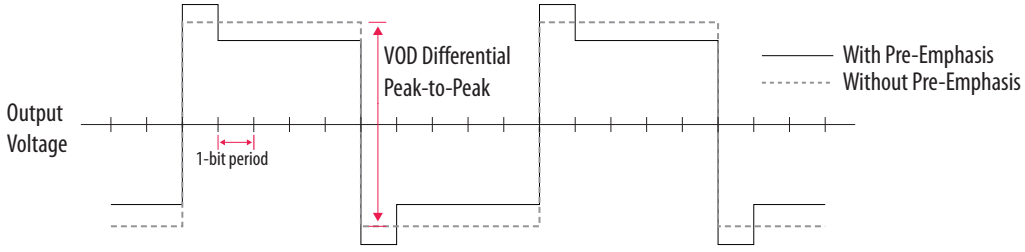
Category	Features	Description
Improve Signal Integrity	Programmable Differential Output Voltage (V_{OD})	Controls the current mode drivers for signal amplitude to handle different trace lengths, various backplanes, and receiver requirements. The actual V_{OD} level is a function of the current setting and the transmitter termination value.
	Programmable Pre-Emphasis	Boosts the high-frequency components of the transmitted signal, which may be attenuated when propagating through the transmission medium. The physical transmission medium can be represented as a low-pass filter in the frequency domain. Variation in the signal frequency response that is caused by attenuation significantly increases the data-dependent jitter and other intersymbol interference (ISI) effects at the receiver end. Using the pre-emphasis feature maximizes the data opening at the far-end receiver. Arria V GZ channels provide three pre-emphasis taps: pre-tap (16 settings), first post-tap (32 settings), and second post-tap (16 settings). Arria V GX, SX, GT and ST provides only one pre-emphasis tap which is first post-tap (32 settings).The pre-tap sets the pre-emphasis on the data bit before the transition. The first post-tap and second post-tap set the pre-emphasis on the transition bit and the following bit, respectively. The pre-tap and second post-tap also provide inversion control, shown by negative values.
	Programmable Slew Rate	Controls the rate of change for the signal transition.
Save Board Space and Cost	On-Chip Biasing	Establishes the required transmitter common-mode voltage (TX V_{CM}) level at the transmitter output. The circuitry is available only if you enable on-chip termination (OCT). When you disable OCT, you must implement off-chip biasing circuitry to establish the required TX V_{CM} level.
	Differential OCT	The termination resistance is adjusted by the calibration circuitry, which compensates for the process, voltage, and temperature variations (PVT). You can disable OCT and use external termination. However, you must implement off-chip biasing circuitry to establish the required TX V_{CM} level. TX V_{CM} is tri-stated when using external termination.
Reduce Power	Programmable V_{CM} Current Strength	Controls the impedance of V_{CM}. A higher impedance setting reduces current consumption from the on-chip biasing circuitry.

Category	Features	Description
Protocol-Specific Function	Transmitter Output Tri-State	Enables the transmitter differential pair voltages to be held constant at the same value determined by the TX V_{CM} level with the transmitter in the high impedance state. The transmitter output tri-state feature is compliant with differential and common-mode voltage levels and operation time requirements for transmitter electrical idle, as specified in the PCI Express Base Specification 2.0 for Gen1 and Gen2 signaling rates, and PCI Express Base Specification 3.0 for Gen3 signaling rates (Arria V GZ only).
	Receiver Detect	Provides link partner detection capability at the transmitter end using an analog mechanism for the receiver detection sequence during link initialization in the Detect state of the PCI Express® (PCIe) Link Training and Status State Machine (LTSSM) states. The circuit detects if there is a receiver downstream by changing the transmitter V_{CM} to create a step voltage and measuring the resulting voltage rise time. For proper functionality, the series capacitor (AC-coupled link) and receiver termination values must comply with the PCI Express Base Specification 2.0 for Gen1 and Gen2 signaling rates and PCI Express Base Specification 3.0 for Gen3 signaling rates (Arria V GZ only). The circuit is clocked using `fixedclk` and requires that the transmitter OCT be enabled with the output tri-stated.

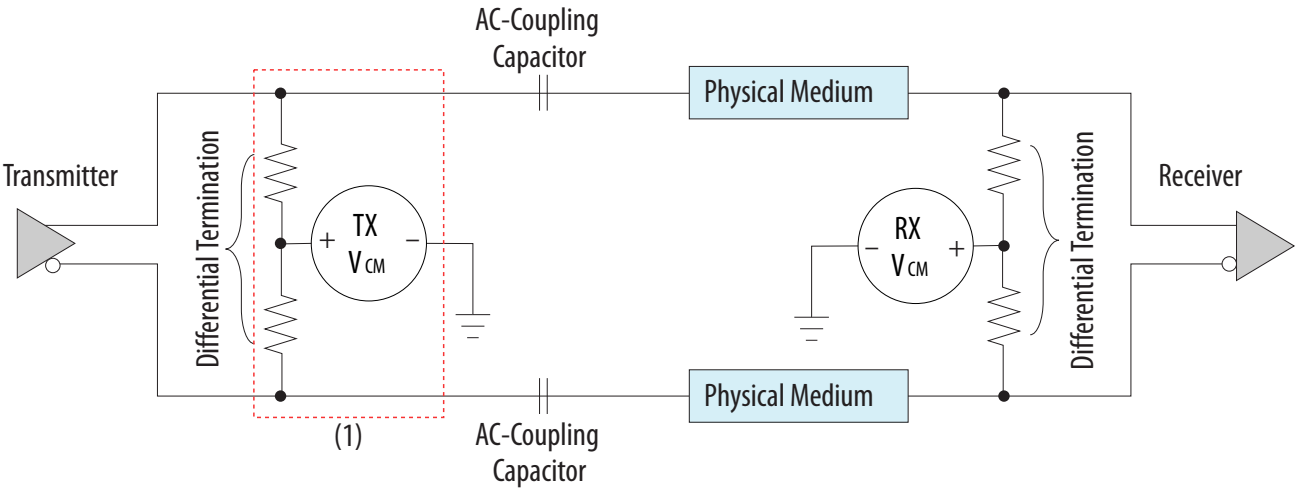
Figure 1-11: Example of Pre-Emphasis Effect on Signal Transmission at Transmitter Output

Shows the signal transmission at the transmitter output with and without applying pre-emphasis post-tap for a 5 Gigabit per second (Gbps) signal with an alternating data pattern of five 1s and five 0s.



The receiver can be AC- or DC-coupled to a transmitter. In an AC-coupled link, the AC-coupling capacitor blocks the transmitter V_{CM}. At the receiver end, the termination and biasing circuitry restores the V_{CM} level that is required by the receiver.

Figure 1-12: AC-Coupled Link with Arria V Transmitter



Notes:
1. When you disable OCT, you must implement external termination and off-chip biasing circuitry to establish the required TX V_{CM} level.

When used in a DC-coupled link, the transmitter V_{cm} is fixed to 0.7 V. The receiver V_{cm} is required to be at 0.7 V. DC coupling is supported for serial data rates up to 3.2 Gbps.

You can DC-couple the Arria V GZ channel transmitter only to another Arria V GZ channel receiver for the entire datarate range from 600 Mbps to 12.5 Gbps so long as the same V_{CM} value is observed.

Figure 1-13: DC-Coupled Link with Arria V Transmitter

Receiver PMA Datapath

Describes the receiver buffer, channel phase-locked loop (PLL) configured for clock data recovery (CDR) operation, and deserializer blocks in the receiver PMA datapath.

Table 1-11: Functional Blocks in the Receiver PMA Datapath

Block	Functionality

Receiver Buffer	• Receives the serial data stream and feeds the stream to the channel PLL if you configure the channel PLL as a CDR.
	• Supports the following features:
	  • Programmable CTLE (Continuous Time Linear Equalization)
	  • Programmable DC gain
	  • Programmable V_{CM} current strength
	  • On-chip biasing for common-mode voltage (RX V_{CM})
	  • I/O standard (1.4 V (Arria V GZ), **PCML**, 1.5 V **PCML**, 2.5 V **PCML**, **LVDS**, **LVPECL**)
	  • Differential OCT (85, 100, 120 and 150 Ω)
	  • Signal detect

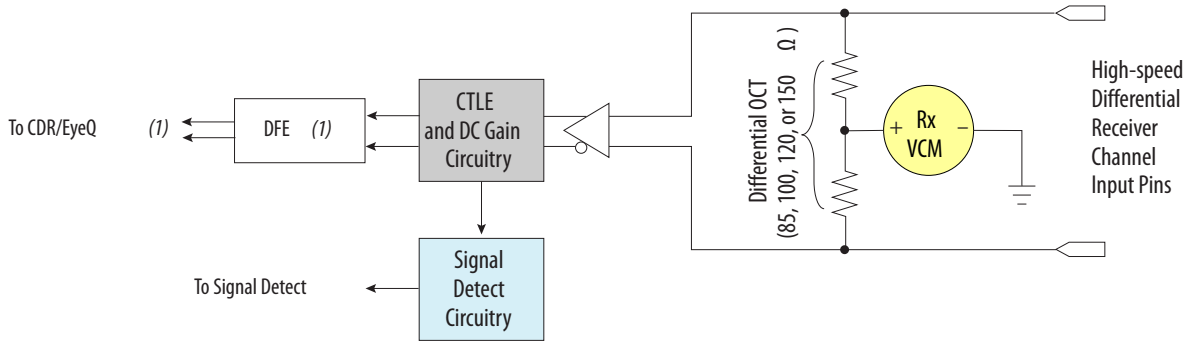
Channel PLL	• Recovers the clock and serial data stream if you configure the channel PLL as a CDR. • Requires offset cancellation to correct the analog offset voltages. • If you do not use the channel PLL as a CDR, you can configure the channel PLL as a CMU PLL for clocking the transceivers. For more information about the channel PLL configured as a CMU PLL, refer to **CMU PLL** on page 1-27.
Deserializer	• Converts the incoming high-speed serial data from the receiver buffer to low-speed parallel data for the receiver PCS. • Receives serial data in LSB-to-MSB order. • Supports the optional clock-slip feature for applications with stringent latency uncertainty requirement. • Supports 8, 10, 16, and 20-bit deserialization factors in Arria V GX, SX, GT, ST, and GZ devices. • Additionally supports the 64 and 80-bit serialization factor for 10-Gbps transceiver channels Arria V ST and GT devices. • Additionally supports the 32, 40, 64, and 80-bit serialization factor in Arria V GZ devices.

Receiver Buffer

The receiver input buffer receives serial data from the `rx_serial_data` port and feeds the serial data to the channel PLL configured as a CDR PLL.

Figure 1-14: Receiver Buffer

Channel PLL configured as a CDR.



Note:
1. Available only in Arria V GZ devices. Arria V GX,SX,GT and ST devices do not have the decision feedback equalizer (DFE) feature.

Modifying programmable values within receiver input buffers can be performed by a single reconfiguration controller for the entire FPGA, or multiple reconfiguration controllers if desired. Within each transceiver bank a maximum of two reconfiguration controllers is allowed; one for the three-transceiver triplet in the upper-half of the bank, and one for the lower-half. This is due to a single slave interface to all PLLs and PMAs within each triplet. Therefore, many triplets can be connected to a single reconfiguration controller, but only one reconfiguration controller can be connected to the three transceivers within any triplet.

Note: A maximum of one reconfiguration controller is allowed per transceiver bank upper-half or lower-half triplet.

Receiver Analog Settings

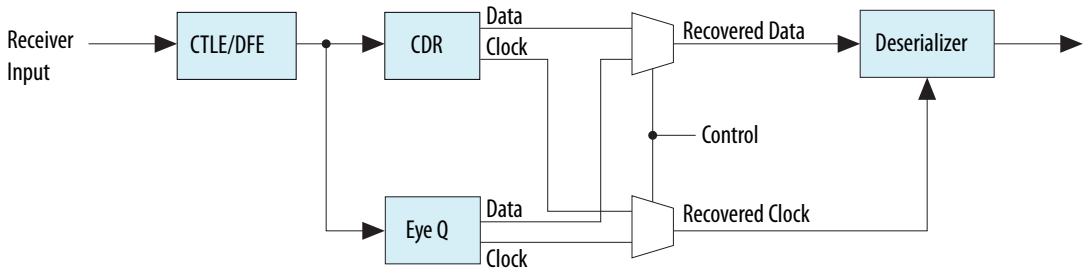
Arria V GZ channels have two receiver analog modes: half-bandwidth and full-bandwidth. The half-bandwidth data rate is up to 6.25 Gbps; the full-bandwidth data rate is from 6.25 Gbps to 12.5 Gbps. You can select which mode to use in the Assignment Editor of the Quartus II software (Receiver Equalizer Gain Bandwidth Select).

Table 1-12: Arria V Receiver Buffer Features

Category	Features	Description
Improve Signal Integrity	Programmable CTLE (Continuous Time Linear Equalization)	Boosts the high-frequency components of the received signal, which may be attenuated when propagating through the transmission medium. The physical transmission medium can be represented as a low-pass filter in the frequency domain. Variation in the signal frequency response that is caused by attenuation leads to data-dependent jitter and other ISI effects, causing incorrect sampling on the input data at the receiver. The amount of the high-frequency boost required at the receiver to overcome signal attenuation depends on the loss characteristics of the physical medium.
	Programmable DC Gain	Provides equal boost to the received signal across the frequency spectrum.
	Decision Feedback Equalization (DFE)	The decision feedback equalization feature consists of a 5-tap equalizer, which boosts the high frequency components of a signal without noise amplification by compensating for inter-symbol interference (ISI). There are two decision feedback equalization modes: manual and auto-adaptation. The DFE is supported only in Arria V GZ devices.
	EyeQ	The EyeQ feature is a debug and diagnosis tool that helps you analyze the received data by measuring the horizontal and vertical eye opening. The EyeQ is supported only in Arria V GZ devices, and not supported in Arria V GX, SX, ST and GT devices. There are two multiplexers for the data and clock which select one path to feed to the deserializer.
Save Board Space and Cost	On-Chip Biasing	Establishes the required receiver common-mode voltage (RX V_{CM}) level at the receiver input. The circuitry is available only if you enable OCT. When you disable OCT, you must implement off-chip biasing circuitry to establish the required RX V_{CM} level.
	Differential OCT	The termination resistance is adjusted by the calibration circuitry, which compensates for the PVT. You can disable OCT and use external termination. However, you must implement off-chip biasing circuitry to establish the required RX V_{CM} level. RX V_{CM} is tri-stated when using external termination.

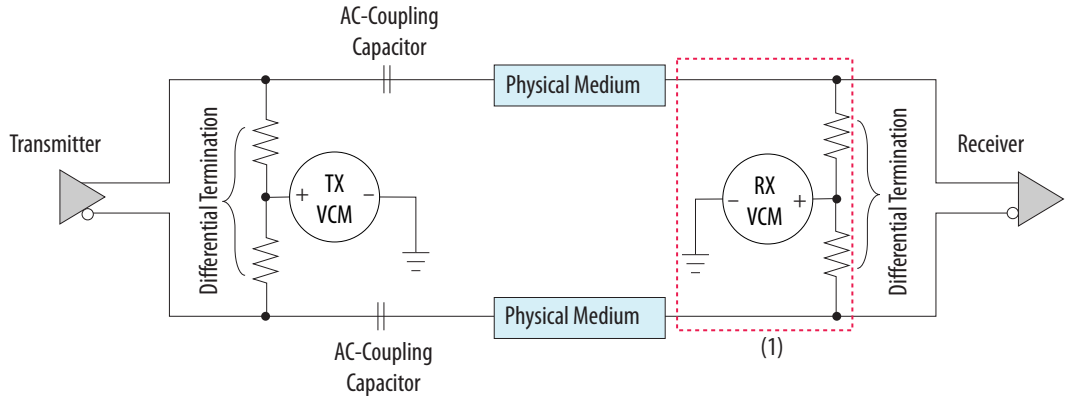
Category	Features	Description
Reduce Power	Programmable V_{CM} Current Strength	Controls the impedance of V_{CM}. A higher impedance setting reduces current consumption from the on-chip biasing circuitry. **Note:** There is no programmable option for Arria V GX, SX, GT and ST devices because only one V_{CM} value is offered for AC coupled link in non-PCIe mode.
Protocol-Specific Function	Signal Detect	Senses if the signal level present at the receiver input is above or below the threshold voltage that you specified. The detection circuitry has a hysteresis response that asserts the status signal only when a number of data pulses exceeding the threshold voltage are detected and deasserts the status signal when the signal level below the threshold voltage is detected for a number of recovered parallel clock cycles. The circuitry requires the input data stream to be 8B/10B-coded. Signal detect is compliant to the threshold voltage and detection time requirements for electrical idle detection conditions as specified in the PCI Express Base Specification 2.0 for Gen1 and Gen2 signaling rates and PCI Express Base Specification 3.0 for Gen3 signaling rates (Arria V GZ only).

Figure 1-15: Receiver and EyeQ Architecture



The receiver can be AC- or DC-coupled to a transmitter. In an AC-coupled link, the AC-coupling capacitor blocks the transmitter V_{CM}. At the receiver end, the termination and biasing circuitry restores the V_{CM} level that is required by the receiver.

Figure 1-16: AC-Coupled Link with Arria V Receiver

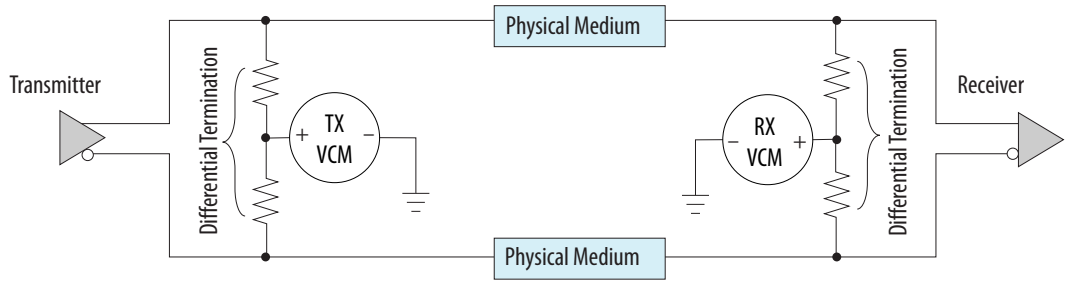


Note:
1. When you disable OCT, you must implement external termination and off-chip biasing circuitry to establish the required RX V_{CM} level.

When used in a DC-coupled link, the transmitter V_{cm} is fixed to 0.7V. The receiver V_{cm} is required to be at 0.7V. DC coupling is supported for serial data rates up to 3.2 Gbps.

You can DC-couple the Arria V GZ channel transmitter only to another Arria V GZ channel receiver for the entire datarate range from 600 Mbps to 12.5 Gbps so long as the same V_{CM} value is observed.

Figure 1-17: DC-Coupled Link with Arria V Receiver



Related Information

- **For more information about the EyeQ feature, refer to the Altera Transceiver PHY IP Core User Guide.**
- **For more information about the Receiver Buffer and electrical specifications, refer to the Arria V Device Datasheet.**

Continuous Time Linear Equalization (CTLE)

Each receiver buffer has five independently programmable equalization circuits that boost the high-frequency gain of the incoming signal, thereby compensating for the low-pass characteristics of the physical medium. The CTLE operates in two modes: manual mode and adaptive equalization (AEQ) mode

Manual Mode

Manual mode allows you to manually adjust the continuous time linear equalization to improve signal integrity. You can statically set the equalizer settings in the IP or you can dynamically change the equalizer settings with the reconfiguration controller IP.

Adaptive Equalization Mode

AEQ mode eliminates the need for manual tuning by enabling the Arria V device to automatically tune the receiver equalization settings based on the frequency content of the incoming signal and comparing that with internally generated reference signals. The AEQ block resides within the PMA of the receiver channel and is available on all GX channels.

Note: AEQ is supported by Arria V GZ devices, but not Arria V GX, GT, SX, and ST devices.

There are three AEQ modes: continuous, one-time, and powerdown:

- Continuous mode—The AEQ continuously monitors the frequency content of the received signal and adapts to the received signal by providing dynamically changing equalizer settings to the receiver.
- One-time mode—The AEQ finds a stable setting of the receiver equalizer and locks to that value. After the stable setting is locked, the equalizer values do not.
- Powerdown mode—The AEQ of the specific channel is placed in standby mode and the CTLE uses the manually set value. Note that the CTLE cannot be bypassed.

You can dynamically switch between these modes.

Related Information

For more information about enabling different options and using them to control the AEQ hardware, see the Altera Transceiver PHY IP Core User Guide.

Channel PLL

If you configure the channel PLL as a CDR PLL, the channel PLL recovers the clock and data from the serial data stream. If you do not use the channel PLL as a CDR PLL, you can configure it as a clock multiplier unit (CMU) PLL for clocking the transceivers.

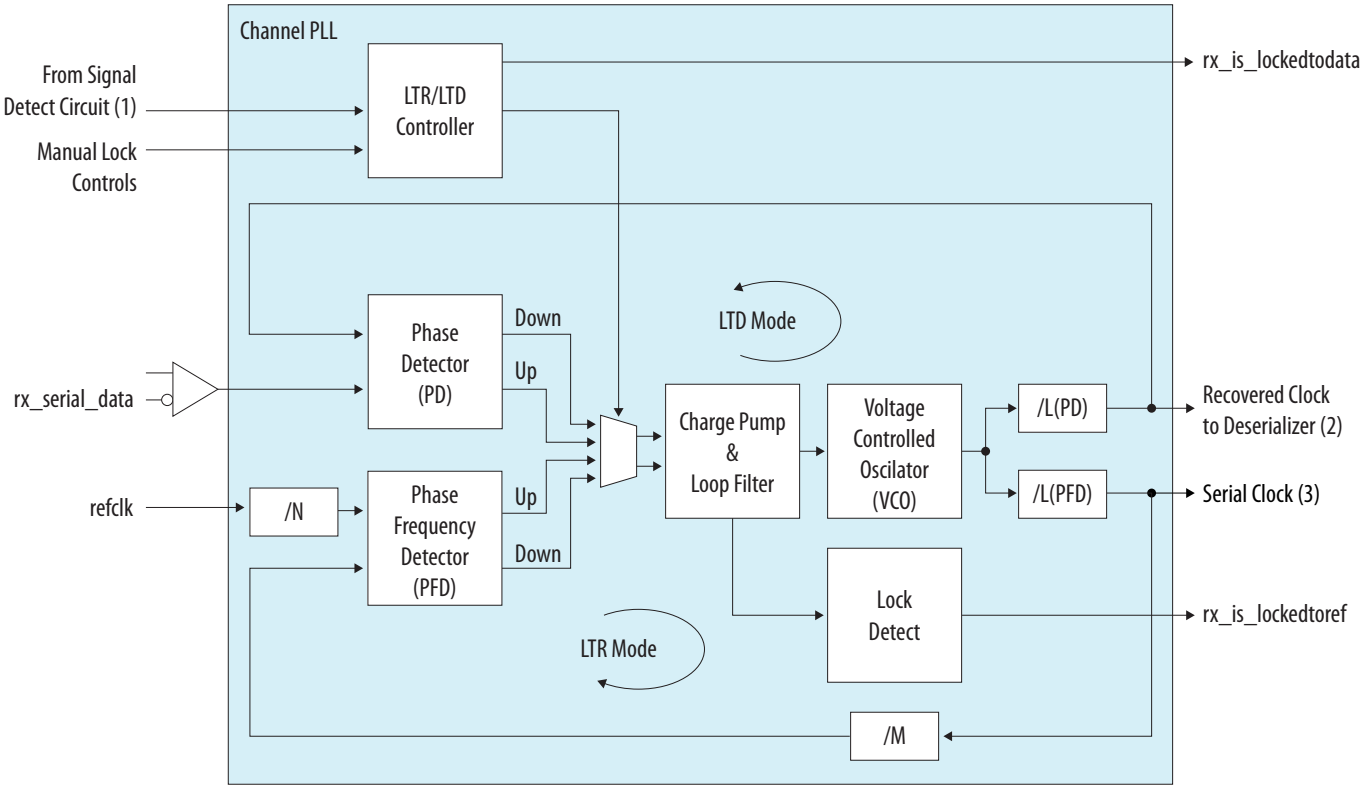
Related Information

CMU PLL on page 1-27
Refer to this section for more information about the channel PLL operation when configured as a CMU PLL.

Channel PLL Architecture

The channel PLL supports operation in either lock-to-reference (LTR) or lock-to-data (LTD) mode.

Figure 1-18: Channel PLL Block Diagram



Notes:
1. Applicable in a PCIe configuration only.
2. Applicable when configured as a CDR PLL.
3. Applicable when configured as a CMU PLL.
4. The PCIe rateswitch control allows dynamic switching between Gen3, Gen2, and Gen1 line rates in a PCIe Gen2 and Gen3 design. In addition, the Arria V GZ PCIe rateswitch control allows dynamic switching between Gen3, Gen2, and Gen1 line rates in a PCIe Gen3 design.

In LTR mode, the channel PLL tracks the input reference clock. The phase-frequency detector (PFD) compares the phase and frequency of the voltage controlled oscillator (VCO) output and the input reference clock. The resulting PFD output controls the VCO output frequency to half the data rate with the appropriate counter (M or L) value given an input reference clock frequency. The lock detect determines whether the PLL has achieved lock to the phase and frequency of the input reference clock.

During normal operation, the CDR must be in LTD mode to recover the clock from the incoming serial data. In LTD mode, the phase detector (PD) in the CDR tracks the incoming serial data at the receiver input. Depending on the phase difference between the incoming data and the CDR output clock, the PD controls the CDR charge pump that tunes the voltage controlled oscillator (VCO).

Note: The phase frequency detector (PFD) is inactive in LTD mode. `rx_is_lockedtoref` toggles randomly and is not significant in LTD mode.

Use the LTR/LTD controller only when you configure the channel PLL as a CDR PLL.

Channel PLL Counters

Table 1-13: Channel PLL Counters

The Quartus® II software automatically selects the appropriate counter values for each transceiver configuration.

Counter	Description	Values
N	Pre-scale counter to divide the input reference clock frequency to the PFD by the N factor	1, 2, 4, 8
M	Feedback loop counter to multiply the VCO frequency above the input reference frequency to the PFD by the M factor	1, 4, 5, 8, 10, 12, 16, 20, 25
L (PFD)	VCO post-scale counter to divide the VCO output frequency by the L factor in the LTR loop	1, 2, 4, 8
L (PD)	VCO post-scale counter to divide the VCO output frequency by the L factor in the LTD loop	1, 2, 4, 8

CDR PLL Operation

Description of Arria V CDR PLL operation modes.

The CDR PLL independently recovers the clock and data from the incoming serial data and sends the clock and data to the deserializer. The CDR PLL supports the full range of data rates.

The CDR PLL requires offset cancellation to correct the analog offset voltages that may exist from process variations between the positive and negative differential signals in the CDR circuitry.

The CDR PLL operates either in LTR mode or LTD mode. After power-up or reset of the receiver PMA, the CDR PLL must first operate in LTR mode to keep the VCO output frequency close to the optimum recovered clock rate.

In LTR mode, the phase detector is not active. When the CDR PLL locks to the input reference clock, you can switch the CDR PLL to LTD mode to recover the clock and data from the incoming serial data.

In LTD mode, the PFD output is not valid and may cause the lock detect status indicator to toggle randomly. When there is no transition on the incoming serial data for an extended duration, you must switch the CDR PLL to LTR mode to wait for the real serial data.

The time needed for the CDR PLL to lock to data depends on the transition density and jitter of the incoming serial data and the parts per million (ppm) difference between the receiver input reference clock and the upstream transmitter reference clock. The receiver PCS must be held in reset until the CDR PLL locks to data and produces a stable recovered clock.

The LTR/LTD controller directs the CDR PLL transition between the LTR and LTD modes. The controller supports operation in both automatic lock mode and manual lock mode.

Related Information

For a detailed description of the offset cancellation process, see Dynamic Reconfiguration in Arria V Devices.

CDR PLL in Automatic Lock Mode

In automatic lock mode, the LTR/LTD controller directs the transition between the LTR and LTD modes when a set of conditions are met to ensure proper CDR PLL operation. The mode transitions are indicated by the `rx_is_lockedtodata` signal. In Arria V GZ devices, the mode transitions are indicated by the `pma_rx_is_lockedtodata` signal.

After power-up or reset of the receiver PMA, the CDR PLL is directed into LTR mode. The controller transitions the CDR PLL from LTR to LTD mode when all the following conditions are met:

- The frequency of the CDR PLL output clock and input reference clock is within the configured ppm frequency threshold setting.
- The phase of the CDR PLL output clock and input reference clock is within approximately 0.08 unit interval (UI) of difference.
- In PCIe configurations only—the signal detect circuitry must also detect the presence of the signal level at the receiver input above the threshold voltage specified in the PCI Express Base Specification 2.0 and PCI Express Base Specification 3.0 (Arria V GZ only).

The controller transitions the CDR PLL from LTD to LTR mode when either of the following conditions is met:

- The difference in between frequency of the CDR PLL output clock and input reference clock exceeds the configured ppm frequency threshold setting.
- In PCIe configurations only—the signal detect circuitry detects the signal level at the receiver input below the threshold voltage specified in the PCI Express Base Specification 2.0 and PCI Express Base Specification 3.0 (Arria V GZ only).
- In Arria V GZ, after switching to LTD mode, the `rx_is_lockedtodata` status signal is asserted. Lock to data takes a minimum of 4 µs, however the actual lock time depends on the transition density of the incoming data and the parts per million (ppm) difference between the receiver input reference clock and the upstream transmitter reference clock. The receiver PCS logic must be held in reset until the CDR produces a stable recovered clock.

If there is no transition on the incoming serial data for an extended duration, the CDR output clock may drift to a frequency exceeding the configured ppm threshold when compared with the input reference clock. In such a case, the LTR/LTD controller transitions the CDR PLL from LTD to LTR mode.

CDR PLL in Manual Lock Mode

In manual lock mode, the LTR/LTD controller directs the transition between the LTR and LTD modes based on user-controlled settings in the `pma_rx_set_locktodata` and `pma_rx_set_locktoref` registers. Manual lock mode provides the flexibility to manually control the CDR PLL mode transitions bypassing the ppm detection as required by certain applications that include, but not limited to, the following:

- Link with frequency differences between the upstream transmitter and the local receiver clocks exceeding the CDR PLL ppm threshold detection capability. For example, a system with asynchronous spread-spectrum clocking (SSC) downspread of –0.5% where the SSC modulation results in a ppm difference of up to 5000.
- Link that requires a faster CDR PLL transition to LTD mode, avoiding the duration incurred by the ppm detection in automatic lock mode.

In manual lock mode, your design must include a mechanism—similar to a ppm detector—that ensures the CDR PLL output clock is kept close to the optimum recovered clock rate before recovering the clock and data. Otherwise, the CDR PLL might not achieve locking to data. If the CDR PLL output clock

frequency is detected as not close to the optimum recovered clock rate in LTD mode, direct the CDR PLL to LTR mode.

Related Information

For information about the proper sequence after power-up reset, see Transceiver Reset Control and Power-Down in Arria V Devices.

Deserializer

The deserializer provides serial-to-parallel data conversion and assumes the data is received LSB first from the receiver buffer. Additionally, the deserializer provides the clock-slip feature.

Clock-Slip

Word alignment in the PCS may contribute up to one parallel clock cycle of latency uncertainty. The clock-slip feature allows word alignment operation with a reduced latency uncertainty by performing the word alignment function in the deserializer. Use the clock slip feature for applications that require deterministic latency.

The deterministic latency state machine in the word aligner from the PCS automatically controls the clock-slip operation. After completing the clock-slip process, the deserialized data is word-aligned into the receiver PCS.

Transmitter PLL

In Arria V GX/GT/SX/ST devices, there are two transmitter PLL sources: CMU PLL and fPLL. In Arria V GZ devices, there are three transmitter PLL sources: ATX PLL, CMU PLL, and fPLL.

Table 1-14: Transmitter PLL Capability and Availability

Transmitter PLL	Serial Data Range	Availability
ATX PLL (4)	0.600 Gbps to 12.5 Gbps	Two transceivers per bank.
CMU PLL	0.611 Gbps to 10.3125 Gbps	Every channel when not used as receiver CDR (only two per transceiver bank capable to drive other channels)
fPLL	0.611 Gbps to 3.125 Gbps	Two per transceiver bank

Auxiliary Transmit (ATX) PLL Architecture

Arria V GZ devices contain two ATX PLLs per transceiver bank that can generate the high-speed clocks for the transmitter channels.

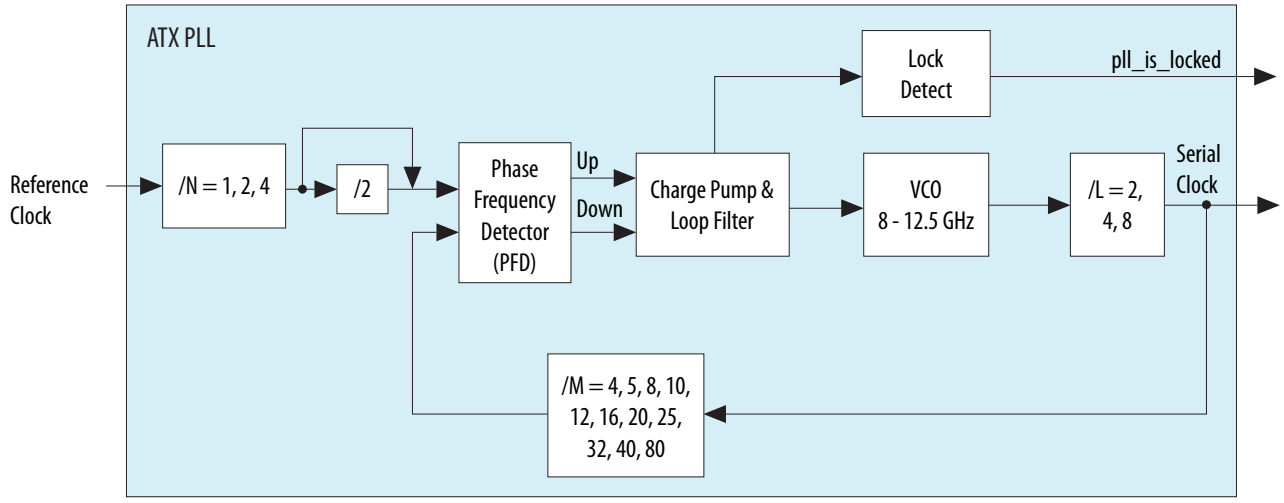
Compared with CMU PLLs, ATX PLLs have lower jitter and do not consume a transceiver channel; however an ATX PLL's frequency range is more limited.

The serial clock from the ATX PLL is routed to the transmitter clock dividers and can be further divided down to half the data rate of the individual channels. For best performance you should use the reference clock input that resides in the same transceiver block as your channel. However, you can use any dedicated reference clocks along the same side of the device to clock the ATX PLL.

(4) ATX PLL only available in Arria V GZ devices.

Note: Altera recommends that all Arria V GZ devices use the ATX PLL for channels operating between 8 to 12.5 Gbps data rates and to use the dedicated reference clock input residing in the same transceiver bank for the selected ATX PLL for best performance

Figure 1-19: ATX PLL Architecture



Related Information

For ATX PLL specifications such as input clock frequency or supported output data ranges, refer to the Arria V Device Datasheet.

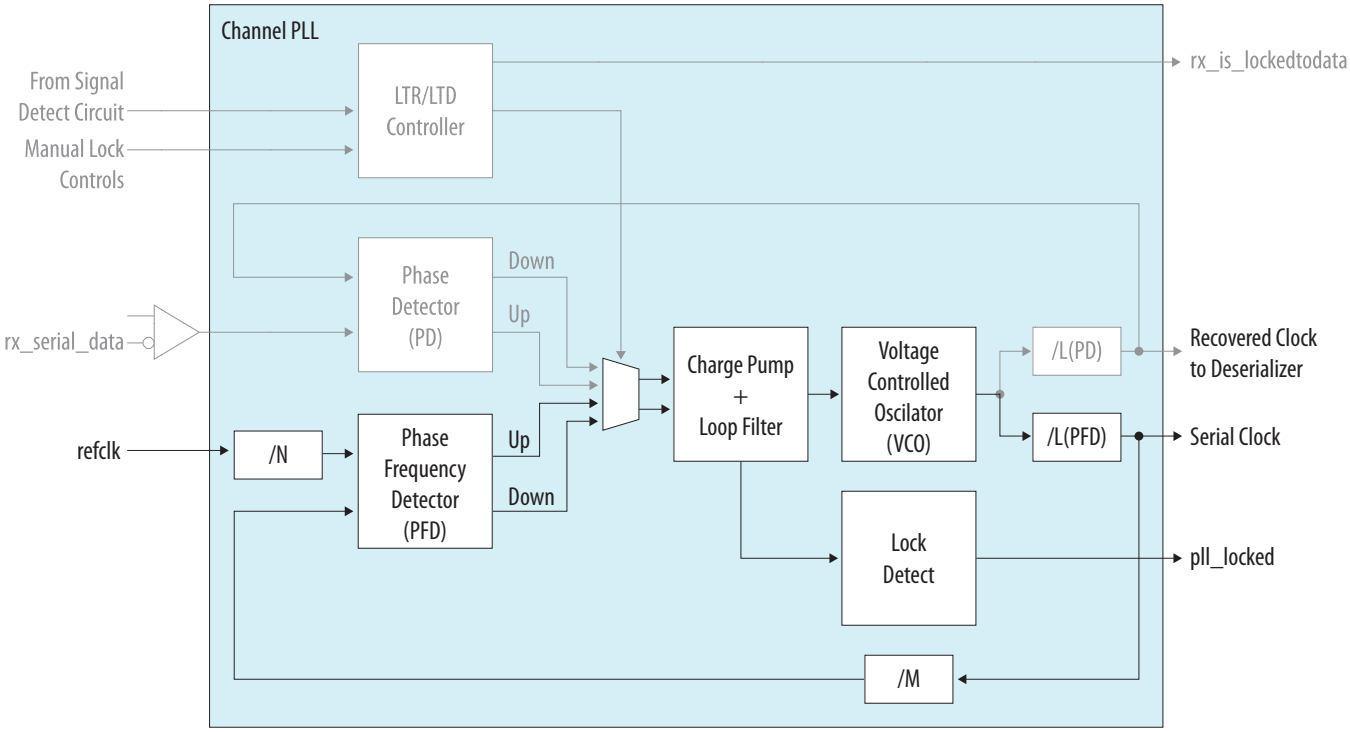
CMU PLL

In Arria V devices, if you do not use the channel PLL as a CDR, you can independently configure every channel PLL as a CMU PLL for clocking the transceivers.

Note: CDR functionality for the receiver is not available when you configure the channel PLL as a CMU PLL—you can use the transceiver channel only as a transmitter.

The CMU PLL operates only in lock-to-reference (LTR) mode and supports the full range of data rates.

Figure 1-20: CMU PLL in Arria V Devices



Using the input reference clock, the CMU PLL synthesizes the serial clock with a frequency that is half of the data rate. The CMU PLL output serial clock feeds the clock divider that resides in the transmitter of the same transceiver channel. Depending on the channel location in a transceiver bank, the CMU PLL of channels 1 and 4 feeds the output clock to the x1 clock lines.

Note: Transmitter PLLs within the upper-half or lower-half of a transceiver bank must be connected to the same Reconfiguration Controller.

Related Information

- **Receiver PMA Datapath** on page 1-16
- **For more information about the input reference clock and transmit PLL, see Transceiver Clocking in Arria V Devices.**

fPLL as Transmitter PLL

In addition to CMU PLL, the fPLL located adjacent to the transceiver banks are available for clocking the transmitters for serial data rates up to 3.125 Gbps.

Related Information

Clock Networks and PLLs in Arria V Devices

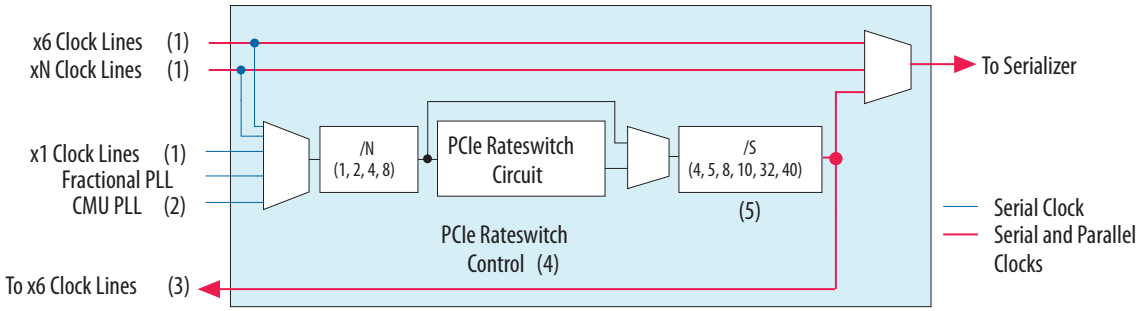
Clock Divider

Each Arria V transmitter channel has a clock divider.

There are two types of clock dividers, depending on the channel location in a transceiver bank:

- Local clock divider—channels 0, 2, 3, and 5 provide serial and parallel clocks to the PMA
- Central clock divider—channels 1 and 4 can drive the x6 and xN clock lines

Figure 1-21: Clock Divider for a Transceiver Channel in Arria V Devices



Notes:
1. For information about the x1, x6, and xN clock lines, see the Related Information.
2. Only from the channel PLL in the same transceiver channel configured as a CMU PLL.
3. Applicable for central clock dividers only (clock dividers in channels 1 and 4).
4. The PCIe rateswitch circuit allows dynamic switching between Gen2 and Gen1 line rates in a PCIe Gen2 design.
5. The divider settings are configured automatically depending on the serialization factor. The selected divider setting is half of the serialization factor. The 32 and 40 divider settings are only available for 10-Gbps channels.

Both types of clock dividers can divide the serial clock input to provide the parallel and serial clocks for the serializer in the channel if you use clocks from the clock lines or transmit PLLs. The central clock divider can additionally drive the x6 clock lines used to bond multiple channels.

In bonded channel configurations, both types of clock dividers can feed the serializer with the parallel and serial clocks directly, without dividing them from the x6 or xN clock lines.

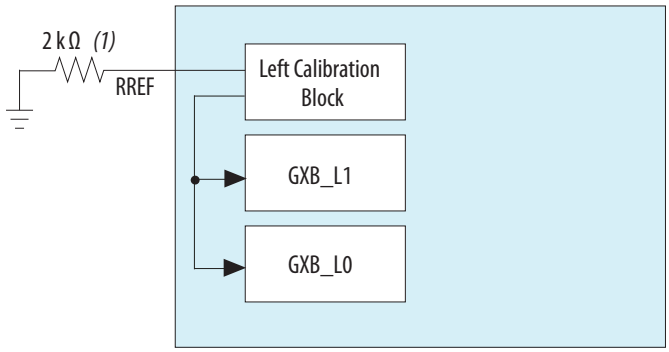
Transceiver Clocking in Arria V Devices

Calibration Block

The calibration block calibrates the differential OCT resistance and analog circuitry in the transceiver PMA to ensure the functionality is independent of PVT. It is also used for duty cycle calibration of the clock line at serial data rates above 4.9152 Gbps.

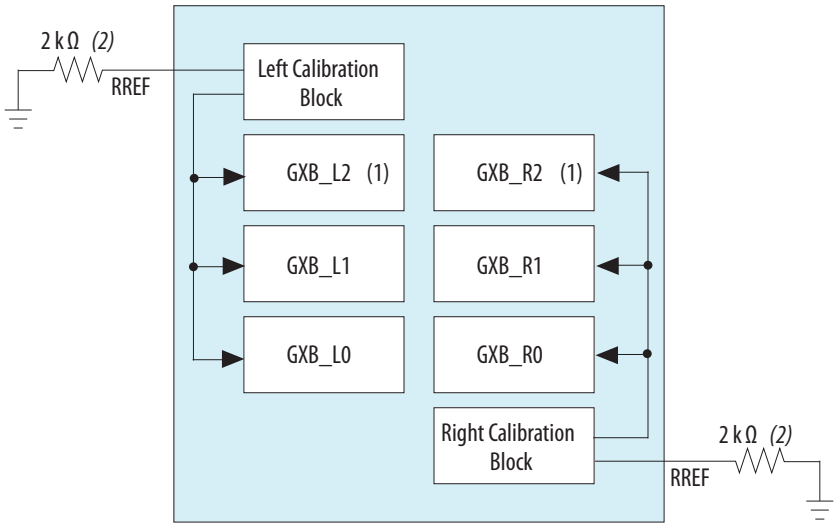
Up to two calibration blocks are available for the Arria V transceiver PMA.

Figure 1-22: Calibration Block Location and Connections in Arria V Devices with Transceivers on the Left Side of the Device Only



Note:
1. In Arria V GZ devices, you must use a 1.8 kΩ (maximum tolerance ± 1%) external resistor.

Figure 1-23: Calibration Block Location and Connections in Arria V Devices with Transceivers on Both Sides of the Device



Notes:
1. GXB_L2 and GXB_R2 banks are only available in some device variants.
2. In Arria V GZ devices, you must use a 1.8 kΩ (maximum tolerance ± 1%) external resistor.

The calibration block generates a constant internal reference voltage that is independent of PVT variations using the external reference resistor. The resulting reference currents are used to calibrate the transceiver banks.

Note: You must connect a separate 2 kΩ (tolerance maximum of ±1%) external resistor on each RREF pin to ground, except for Arria GZ devices. In Arria V GZ devices, you must use a 1.8 kΩ (maximum

tolerance +/- 1%) external resistor. To ensure the calibration block operates properly, the RREF resistor connection in the board must be free from external noise.

Offset Cancellation in the Receiver Buffer and Receiver CDR

Process variation in smaller process silicon can lead to a V_{CM} offset between the p and n signals within the differential buffers. Arria V GZ devices have an automatic calibration in their receiver buffers to remove this V_{CM} offset.

You must use the reconfiguration controller IP for offset cancellation to take place. Calibration does not occur during transceiver reset, only during device configuration. Any signals that may appear on the receiver pin do not affect calibration because the receiver buffers are disconnected during calibration.

Note: A maximum of one reconfiguration controller is allowed per transceiver bank upper-half or lower-half triplet.

ATX PLL Calibration for Arria V GZ Devices

ATX PLL calibration optimizes the ATX PLL VCO settings for the desired output frequency. The reconfiguration controller IP must be instantiated for this calibration to run. The calibration occurs one time after device initialization.

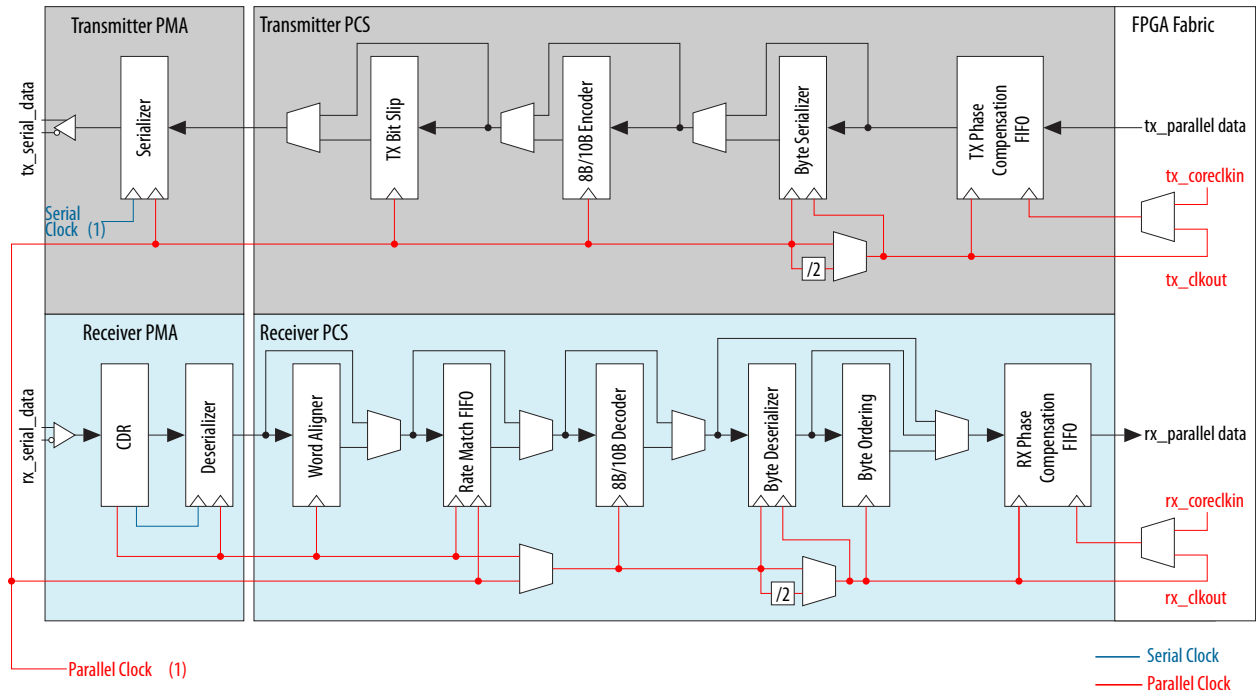
PCS Architecture

The PCS architecture of Arria V GX/GT/SX/ST devices are slightly different from the GZ devices.

The GZ has three types of PCS blocks: standard PCS block, a 10G PCS block and a PCIe Gen3 PCS block.

The GX, SX, GT and ST devices have only one type of PCS block, which is similar to the GZ standard PCS block, except for the data rate support. The GX and GT PCS supports up to 6.5536 Gbps while the GZ supports up to 9.8 Gbps. The 10G PCS of the GZ supports 12.5 Gbps, and the PCIe Gen3 PCS supports the PCIe Gen3 Base specification.

Figure 1-24: Transceiver Channel PCS in Arria V Devices



Note:
1. The serial and parallel clocks are sourced from the clock divider.

Note: For Arria V GT and ST devices, the PCS is not available when using the 10-Gbps channels; only the PMA is available. You must implement the PCS functions required for the interface using user logic in the FPGA fabric with an 80-bit FPGA fabric-transceiver width.

Arria V GZ transceiver PCS blocks fully support data rates up to 12.5 Gbps You have the option to bypass the PCS using the PMA direct mode.

Table 1-15: PCS Datapath Configurations

Parameter	Single-Width	Double-Width
PMA–PCS Interface Width	8 or 10 bit	16 or 20 bit
FPGA Fabric–Transceiver Interface Width	8 or 10 bit 16 or 20 bit (5)	16 or 20 bit 32 or 40 bit (5)
Supported configurations	PCIe Gen1, Gen2, and Gen3 XAUI Custom	Custom

(5) The byte serializer and deserializer are enabled.

Parameter	Single-Width	Double-Width
Data rate range in a custom configuration	0.6 to 3.75 Gbps	1.0 to 11 Gbps

Transmitter PCS Datapath for Arria V GX, SX, GT, and ST Devices and Arria V GZ Standard PCS

This section describes the transmitter phase compensation FIFO, byte serializer, 8B/10B encoder, and transmitter bit-slip blocks in the transmitter PCS datapaths.

Table 1-16: Functional Blocks in the Transmitter PCS Datapath

Block	Functionality
Transmitter Phase Compensation FIFO	• Compensates for the phase difference between the low-speed parallel clock and the FPGA fabric interface clock when interfacing the transmitter PCS with the FPGA fabric directly or with the PCIe hard IP block • Supports operation in phase compensation and registered modes
Byte Serializer	• Divides the FPGA fabric–transceiver interface frequency in half at the transmitter channel by doubling the transmitter input datapath width • Allows the transmitter channel to operate at higher data rates with the FPGA fabric–transceiver interface frequency that is within the maximum limit • Supports operation in double-width modes
8B/10B Encoder	• Generates 10-bit code groups from 8-bit data and 1-bit control identifier, in compliance with Clause 36 of the IEEE 802.3 specification • Supports operation in single- and double-width modes, and running disparity control
Transmitter Bit-Slip	• Enables user-controlled, bit-level delay in the data prior to serialization for serial transmission • Supports operation in single- and double-width modes

Transmitter Phase Compensation FIFO

The transmitter phase compensation FIFO is four words deep and interfaces the control and data signals between the transmitter PCS and FPGA fabric or PCIe hard IP block.

The FIFO supports the following operations:

- Phase compensation mode with various clocking modes on the read clock and write clock
- Registered mode with only one clock cycle of datapath latency

Phase Compensation Mode

The transmitter phase compensation FIFO compensates any phase difference between the read and write clocks for the transmitter control and data signals.

The low-speed parallel clock feeds the read clock; the FPGA fabric interface clock feeds the write clock. The clocks must have 0 ppm difference in frequency or a FIFO underrun or overflow condition may result.

The transmitter phase compensation FIFO supports various clocking modes on the read and write clocks depending on the transceiver configuration.

Related Information

For a detailed description of transmitter datapath interface clocking modes when using the transmitter phase compensation FIFO, see Transceiver Clocking in Arria V Devices.

Registered Mode

To eliminate the FIFO latency uncertainty for applications with stringent datapath latency uncertainty requirements, bypass the FIFO functionality in registered mode to incur only one clock cycle of datapath latency when interfacing the transmitter channel to the FPGA fabric. Configure the FIFO to registered mode when interfacing the transmitter channel to the PCIe hard IP block to reduce datapath latency. In registered mode, the low-speed parallel clock that is used in the transmitter PCS clocks the FIFO.

Byte Serializer

The byte serializer allows the transmitter channel to operate at higher data rates in a configuration that exceeds the FPGA fabric–transceiver interface frequency limit.

The byte serializer supports operation in single- and double-width modes. The datapath clock rate at the output of the byte serializer is twice the FPGA fabric–transmitter interface clock frequency. The byte serializer forwards the least significant word first followed by the most significant word.

Note: You must use the byte serializer in configurations that exceed the maximum frequency limit of the FPGA fabric–transceiver interface.

Table 1-17: Transmitter Input Datapath Conversion

Mode	Transmitter Input Datapath Width	Byte Serializer Output Datapath Width	Byte Serializer Output Ordering
Single Width	16	8	Least significant 8 bits of the 16-bit input first
	20	10	Least significant 10 bits of the 20-bit input first
Double Width	32	16	Least significant 16 bits of the 32-bit input first
	40	20	Least significant 20 bits of the 40-bit input first

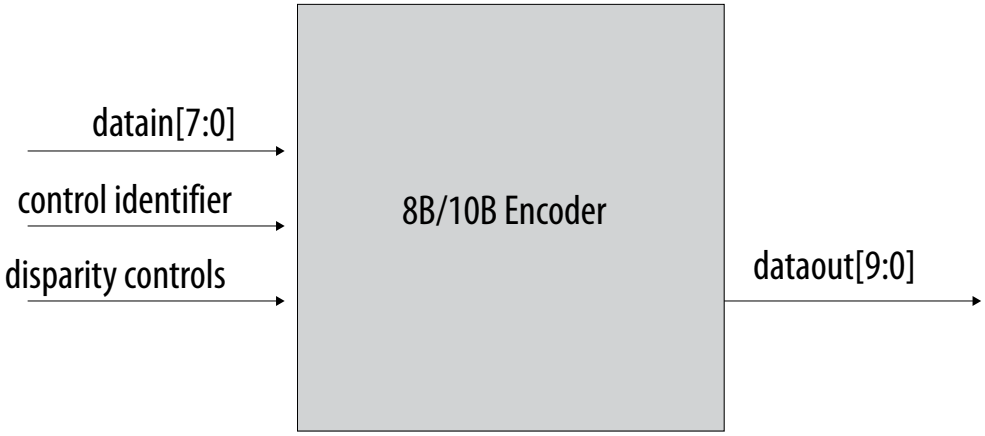
8B/10B Encoder

The 8B/10B encoder supports operation in single- and double-width modes with the running disparity control feature.

8B/10B Encoder in Single-Width Mode

In single-width mode, the 8B/10B encoder generates 10-bit code groups from 8-bit data and 1-bit control identifier with proper disparity according to the PCS reference diagram in Clause 36 of the IEEE 802.3 specification. The 10-bit code groups are generated as valid data code-groups (/Dx.y/) or special control code-groups (/Kx.y/), depending on the 1-bit control identifier.

Figure 1-25: 8B/10B Encoder Diagram in Single-Width Mode



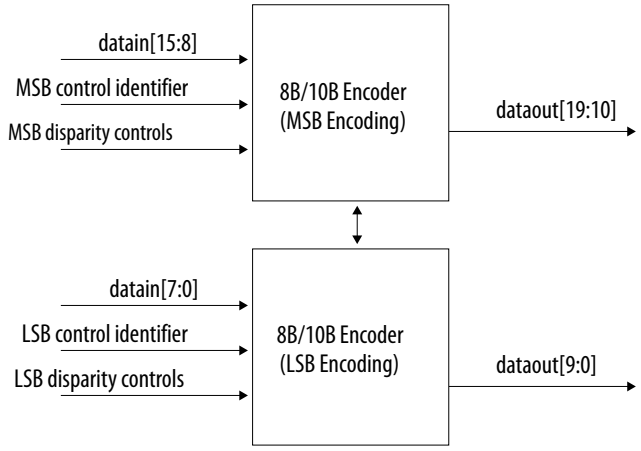
The IEEE 802.3 specification identifies only 12 sets of 8-bit characters as /Kx.y/. If other sets of 8-bit characters are set to encode as special control code-groups, the 8B/10B encoder may encode the output 10-bit code as an invalid code (it does not map to a valid /Dx.y/ or /Kx.y/ code), or unintended valid /Dx.y/ code, depending on the value entered.

8B/10B Encoder in Double-Width Mode

In double-width mode, two 8B/10B encoders are cascaded to generate two sets of 10-bit code groups from 16-bit data and two 1-bit control identifiers.

When receiving the 16-bit data, the 8-bit LSByte is encoded first, followed by the 8-bit MSByte.

Figure 1-26: 8B/10B Encoder Diagram in Double-Width Mode



Running Disparity Control

The 8B/10B encoder automatically performs calculations that meet the running disparity rules when generating the 10-bit code groups.

The running disparity control feature provides user-controlled signals (`tx_dispval` and `tx_forcedisp`) to manually force encoding into a positive or negative current running disparity code group. When enabled, the control overwrites the current running disparity value in the encoder based on user-controlled signals, regardless of the internally-computed current running disparity in that cycle.

Note: Using the running disparity control may temporarily cause a running disparity error at the receiver.

Encoder Output During Reset Sequence

Figure 1-27: 8B/10B Encoder Output During and After Reset Conditions

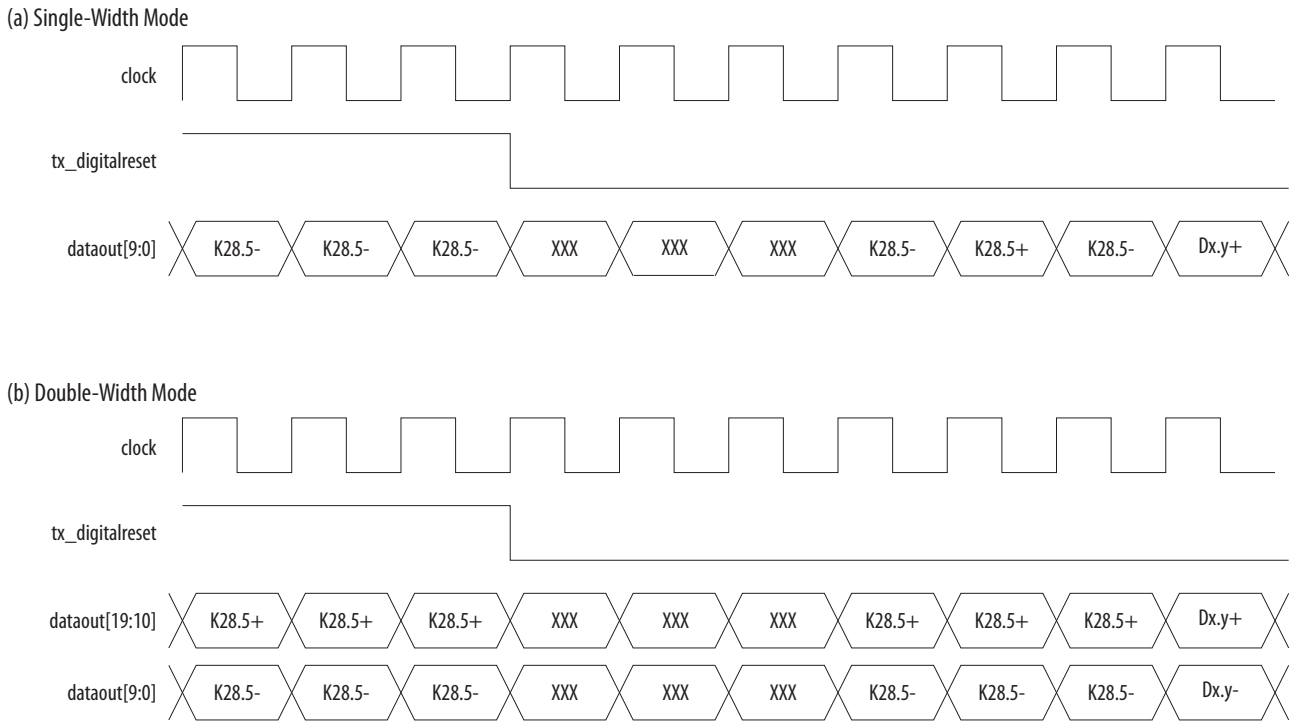


Table 1-18: 8B/10B Encoder Output During and After Reset Conditions

Operation Mode	During 8B/10B Reset	After 8B/10B Reset Release
Single Width	Continuously sends the / K28.5/ code from the RD– column	Some “don’t cares” due to pipelining in the transmitter channel, followed by three /K28.5/ codes with proper disparity—starts with negative disparity—before sending encoded 8-bit data at its input.
Double Width	Continuously sends the / K28.5/ code from the RD– column on LSByte and the / K28.5/ code from the RD+ column on MSByte	Some “don't cares” due to pipelining in the transmitter channel, followed by: • Three /K28.5/ codes from the RD– column before sending encoded 8-bit data at its input on LSByte. • Three /K28.5/ codes from the RD+ column before sending encoded 8-bit data at its input on MSByte.

Transmitter Bit-Slip

The transmitter bit-slip enables a bit-level delay insertion to the data prior to serialization for the serial transmission. The transmitter bit-slip supports operation in single- and double-width modes. Each bit slipped at the transmitter incurs one serial bit of datapath latency.

Table 1-19: Bits Slip Allowed with the `tx_bitslipboundaryselect` Signal

Operation Mode	Maximum Bit-Slip Setting
Singe width (8- or 10-bit)	9
Double width (16- or 20-bit)	19

Receiver PCS Datapath for Arria V GX, SX, GT, and ST Devices and Arria V GZ Standard PCS

Table 1-20: Functional Blocks in the Arria V GX/GT/SX/ST 6-Gbps Receiver PCS and Arria V GZ Standard PCS Datapaths

Block	Functionality
Word Aligner	• Searches for a predefined alignment pattern in the deserialized data to identify the correct boundary and restores the word boundary during link synchronization • Supports an alignment pattern length of 7, 8, 10, 16, 20, or 32 bits • Supports operation in four modes—manual alignment, bit-slip, automatic synchronization state machine, and deterministic latency state machine—in single- and double-width configurations • Supports the optional programmable run-length violation detection, polarity inversion, bit reversal, and byte reversal features
Rate Match FIFO	• Compensates for small clock frequency differences of up to ±300 ppm—600 ppm total—between the upstream transmitter and the local receiver clocks by inserting or deleting skip symbols when necessary • Supports operation that is compliant to the clock rate compensation function in supported protocols
8B/10B Decoder	• Receives 10-bit data and decodes the data into an 8-bit data and a 1-bit control identifier—in compliance with Clause 36 of the IEEE 802.3 specification • Supports operation in single- and double-width modes
Byte Deserializer	• Divides the FPGA fabric–transceiver interface frequency in half at the receiver channel by doubling the receiver output datapath width • Allows the receiver channel to operate at higher data rates with the FPGA fabric–transceiver interface frequency that is within the maximum limit • Supports operation in double-width modes
Byte Ordering	• Searches for a predefined pattern that must be ordered to the LSByte position in the parallel data going to the FPGA fabric when you enable the byte deserializer
Receiver Phase Compensation FIFO	• Compensates for the phase difference between the low-speed parallel clock and the FPGA fabric interface clock when interfacing the receiver PCS with the FPGA fabric directly or with the PCIe hard IP block • Supports operation in phase compensation and registered modes

Word Aligner

The Word Aligner provides word boundary restoration during link synchronization.

Parallel data at the input of the receiver PCS loses the word boundary of the upstream transmitter from the serial-to-parallel conversion in the deserializer. The word aligner provides word boundary restoration during link synchronization with the following four modes:

- Manual alignment mode
- Bit-slip mode
- Automatic synchronization state machine mode
- Deterministic latency state machine mode

The word aligner searches for a predefined alignment pattern in the deserialized data to identify the correct boundary and restores the word boundary during link synchronization. The alignment pattern is predefined for standard serial protocols according to the respective protocol specifications to achieve synchronization or you can specify the settings with a custom word alignment pattern for proprietary protocol implementations. Except for bit-slip mode, after completing word alignment, the deserialized data is synchronized to have the word alignment pattern at the LSB portion of the aligned data.

In addition to restoring the word boundary, the word aligner also supports optional features.

Table 1-21: Optional Word Aligner Features

Feature	Availability
Programmable Run-Length Violation Detection	All transceiver configurations
Receiver Polarity Inversion	All transceiver configurations except PCIe
Receiver Bit Reversal	Custom single- and double-width configurations only
Receiver Byte Reversal	Custom double-width configuration only

The operation mode and alignment pattern length support varies depending on the word aligner configurations.

Table 1-22: Word Aligner Operation Mode and Pattern Length Support

PCS Mode	PMA–PCS Interface Width	Word Aligner Mode	Alignment Pattern Length
Single Width	8 bits	Manual alignment	8 bits or 16 bits
		Bit-slip	–
	10 bits	Manual alignment	7 or 10 bits
		Bit-slip	–
		Automatic synchronization state machine	7 or 10 bits (6)
		Deterministic latency state machine	10 bits (7)
Double Width	16 bits	Manual alignment	8, 16, or 32 bits
		Bit-slip	–
	20 bits	Manual alignment	7, 10, 20, or 40 bits
		Bit-slip	–
		Deterministic latency state machine	10 bits (7)

When the 8B/10B encoder/decoder is enabled, the word aligner detects both positive and negative disparities of the alignment pattern. For example, if you specify a /K28.5/ (b'0011111010) pattern as the comma, `rx_patterndetect` is asserted if b'0011111010 or b'1100000101 is detected in the incoming data.

Word Aligner in Manual Alignment Mode

In manual alignment mode, the word alignment operation is manually controlled with the `rx_std_wa_patternalign` input signal or the `rx_enapatternalign` register.

Depending on the configuration, controlling the `rx_std_wa_patternalign` signal enables the word aligner to look for the predefined word alignment pattern in the received data stream. A value 1 at the `rx_patterndetect` register indicates that the word alignment pattern is detected . A value 1 at the `rx_syncstatus` register indicates that the word aligner has successfully synchronized to the new word boundary.

Manual word alignment can be also triggered by writing a value 1 to `rx_enapatternalign` register. The word alignment is triggered in the next parallel clock cycle when a 0 to 1 transition occurs on the `rx_enapatternalign` register.

(6) For PCIe implementation, the word aligner is configured using the automatic synchronization state machine with alignment pattern length of 10 bits.

(7) For more information about CPRI in deterministic latency state machine, refer to the *CPRI Enhancements* section of the **Transceiver Protocol Configurations in Arria V Devices** chapter.

After rx_syncstatus is asserted and if the incoming data is corrupted causing an invalid code group, rx_syncstatus remains asserted. The rx_errdetect register will be set to 1 (indicating RX 8B/10B error detected). When this happens, the manual alignment mode is not be able to de-assert the rx_syncstatus signal. You must manually assert rx_digitalreset or manually control rx_std_wa_patternalign to resynchronize a new word boundary search whenever rx_errdetect shows an error.

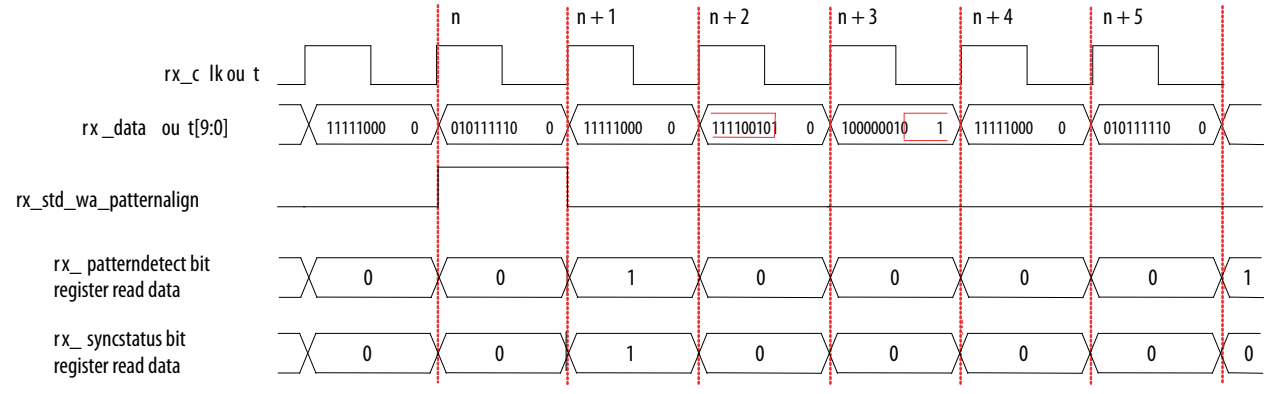
Table 1-23: Word Aligner Operations in Manual Alignment Mode

PCS Mode	PMA–PCS Interface Width	Word Alignment Operation
Single Width	8 bits or 10 bits	1. After the rx_digitalreset signal deasserts, assert rx_std_wa_patternalign signal for one parallel clock cycle for the word aligner to look for the predefined word alignment pattern in the received data stream and synchronize to the new word boundary. 2. Any alignment pattern found thereafter in a different word boundary does not cause the word aligner to resynchronize to this new word boundary if the rx_std_wa_patternalign signal is deasserted. 3. To resynchronize to a new word boundary, assert the rx_std_wa_patternalign signal for another parallel clock cycle. 4. If you keep the rx_std_wa_patternalign signal asserted continuously, before the signal rx_digitalreset is deasserted, the word aligner updates the word boundary when the first alignment pattern is found, even though rx_std_wa_patternalign signal was not asserted for one parallel clock cycle to trigger the word alignment operation. 5. If you keep the rx_std_wa_patternalign signal deasserted, the word aligner maintains the current word boundary even when it finds the alignment pattern in a new word boundary. 6. When the word aligner synchronizes to the new word boundary, the rx_syncstatus register will have a value 1 for one parallel clock cycle. The rx_patterndetect register will have a value 1 whenever a word alignment pattern is found for one parallel clock cycle regardless of whether the word aligner is triggered to align to the new word boundary or not.

PCS Mode	PMA–PCS Interface Width	Word Alignment Operation
Double Width	16 bits or 20 bits	1. After the rx_digitalreset signal deasserts, regardless of whether rx_std_wa_patternalign status signal is asserted or deasserted, the word aligner synchronizes to the first predefined alignment pattern found. 2. Any alignment pattern found thereafter in a different word boundary does not cause the word aligner to resynchronize to this new word boundary. 3. To resynchronize to the new word boundary, assert the rx_std_wa_patternalign signal for one parallel clock cycle. 4. When the word aligner synchronizes to the new word boundary, the rx_syncstatus register will have a value 1 till the rx_digitalreset signal is deasserted or rx_std_wa_patternalign signal is asserted again. The rx_patterndetect register will have a value 1 whenever a word alignment pattern is found for one parallel clock cycle regardless of whether the word aligner is triggered to align to the new word boundary or not.

The configuration selected for this example is word aligner operation in single width with 10-bit PMA-PCS interface mode. In this example, a /K28.5/ (10'b0101111100) is specified as the word alignment pattern. The word aligner aligns to the /K28.5/ alignment pattern in the n^{th} cycle because the rx_std_wa_patternalign signal is asserted during the n^{th} cycle. The rx_syncstatus register has a value 1 in the next parallel clock cycle, indicating alignment to a new word boundary. The rx_patterndetect signal also goes high for one clock cycle indicating word alignment pattern detection. At time n + 1, the rx_std_wa_patternalign signal is deasserted to instruct the word aligner to lock the current word boundary. The alignment pattern is detected again in a new word boundary across cycles n + 2 and n + 3. The word aligner does not align to this new word boundary because the rx_std_wa_patternalign signal is set to 0. The /K28.5/ word alignment pattern is detected again in the current word boundary during cycle n + 5, causing the rx_patterndetect to have a value 1 in the next parallel clock cycle.

Figure 1-28: Word Aligner in Manual Alignment Mode



Note: If the word alignment pattern is known to be unique and does not appear between word boundaries, you can continuously assert `rx_std_wa_patternalign` signal or set the `rx_enapatternalign` register to 1 at all times because there is no possibility of false word alignment. If there is a possibility of the word alignment pattern occurring across word boundaries, you must control the number of clock cycles that the `rx_std_wa_patternalign` is asserted or the number of clock cycles the `rx_enapatternalign` register is set to 1 to avoid re-alignment to an incorrect word boundary.

Bit-Slip Mode

In bit-slip mode, the word alignment is achieved by manually controlling the data slip with the `rx_std_bitslip` signal.

Slipping the received data by one bit effectively shifts the word boundary by one bit. You can implement a controller in the FPGA fabric to iteratively control the `rx_std_bitslip` signal until the word aligner output matches the predefined word alignment pattern to achieve synchronization.

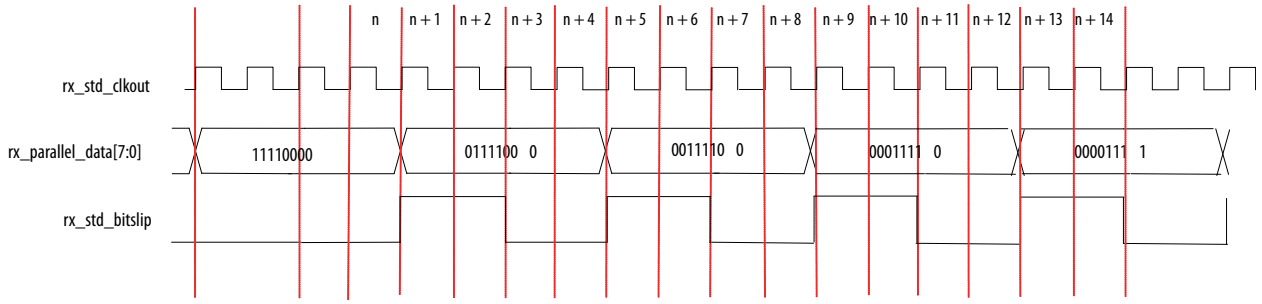
Table 1-24: Word Aligner in Bit-Slip Mode

PCS Mode	PMA–PCS Interface Width (bits)	Word Alignment Operation
Single Width	8	1. At every rising edge to the `rx_std_bitslip` signal, the word aligner slips one bit into the received data. 2. When bit-slipping shifts a complete round of the data bus width, the word boundary is back to the original boundary. 3. Check the received data, `rx_parallel_data` after every bit slip operation whether the predefined word alignment pattern is visible in the new word boundary. When the word alignment pattern is visible in the new word boundary, the alignment process is completed and the bit-slip operation can be stopped.
	10	
Double Width	16	
	20	

Note: For every bit slipped in the word aligner, the earliest bit received is lost.

For this example, consider that 8'b11110000 is received back-to-back and 16'b0000111100011110 is the predefined word alignment pattern. A rising edge on the `rx_std_bitslip` signal at time n + 1 slips a single bit 0 at the MSB position, forcing the `rx_parallel_data` to 8'b01111000. Another rising edge on the `rx_std_bitslip` signal at time n + 5 forces `rx_parallel_data` to 8'b00111100. Another rising edge on the `rx_std_bitslip` signal at time n + 9 forces `rx_parallel_data` to 8'b00011110. Another rising edge on the `rx_std_bitslip` signal at time n + 13 forces the `rx_parallel_data` to 8'b00001111. At this instance, `rx_parallel_data` in cycles n + 12 and n + 13 is 8'b00011110 and 8'b00001111, respectively, which matches the specified 16-bit alignment pattern 16'b0000111100011110.

Figure 1-29: Word Aligner Configured in Bit Slip Mode



Note: Bit slip operation can also be triggered by a 0 to 1 transition in the `rx_bitslip` register.

Word Aligner in Automatic Synchronization State Machine Mode

In automatic synchronization state machine mode, a programmable state machine determines the moment that the word aligner has either achieved synchronization or lost synchronization.

You can configure the state machine to provide hysteresis control during link synchronization and throughout normal link operation. Depending on your protocol configurations, the state machine parameters are automatically configured so they are compliant with the synchronization state machine in the respective protocol specification.

Table 1-25: State Machine Parameters for the Word Aligner in Automatic Synchronization State Machine Mode

Parameter	Values
Number of valid synchronization code groups or ordered sets received to achieve synchronization	1–256
Number of erroneous code groups received to lose synchronization	1–64
Number of continuous good code groups received to reduce the error count by one	1–256

Table 1-26: Word Aligner Operation in Automatic Synchronization State Machine Mode

PCS Mode	PMA–PCS Interface Width	Word Alignment Operation
Single Width	10 bits	1. After the rx_digitalreset signal deasserts, the word aligner starts looking for the predefined word alignment pattern, or its complement, in the received data stream and automatically aligns to the new word boundary. 2. Synchronization is achieved only after the word aligner receives the programmed number of valid synchronization code groups in the same word boundary and is indicated by the value 1 in rx_syncstatus register. The rx_syncstatus register contains a value 0 if the word aligner has lost synchronization. 3. Loss of synchronization occurs when the word aligner receives the programmed number of erroneous code groups without receiving the intermediate good code groups and is indicated by the value 0 in the rx_syncstatus register. 4. The word aligner may achieve synchronization again after receiving a new programmed number of valid synchronization code groups in the same word boundary.

Word Aligner in Deterministic Latency State Machine Mode

In deterministic latency state machine mode, word alignment is achieved by performing a clock-slip in the deserializer until the deserialized data coming into the receiver PCS is word-aligned.

The state machine controls the clock-slip process in the deserializer after the word aligner has found the alignment pattern and identified the word boundary. Deterministic latency state machine mode offers a reduced latency uncertainty in the word alignment operation for applications that require deterministic latency.

After rx_syncstatus is asserted and if the incoming data is corrupted causing an invalid code group, rx_syncstatus remains asserted. The rx_errdetect register will be set to 1 (indicating RX 8B/10B error detected). When this happens, the manual alignment mode is not be able to de-assert the rx_syncstatus signal. You must manually assert rx_digitalreset or manually control rx_std_wa_patternalign to resynchronize a new word boundary search whenever rx_errdetect shows an error.

PCS Mode	PMA–PCS Interface Width	Word Alignment Operation
Single Width	10 bits	1. After `rx_digitalreset` deasserts, the word aligner starts looking for the predefined word alignment pattern, or its complement, in the received data stream and automatically aligns to the new word boundary. 2. After the pattern is found and the word boundary is identified, the state machine controls the clock-slip process in the deserializer. 3. When the clock-slip is complete, the deserialized data coming into the receiver PCS is word-aligned and is indicated by the value 1 in the `rx_syncstatus` register until `rx_digitalreset` is deasserted. 4. To resynchronize to the new word boundary, the Avalon-MM register `rx_enapatternalign` (not available as a signal) must be reasserted to initiate another pattern alignment. Asserting `rx_enapatternalign` may cause the extra shifting in the RX datapath if `rx_enablepatternalign` is asserted while bit slipping is in progress. Consequently, `rx_enapatternalign` should only be asserted under the following conditions: • `rx_syncstatus` is asserted • `rx_bitslipboundaryselectout` changes from a non-zero value to zero or 1 5. When the word aligner synchronizes to the new word boundary, `rx_syncstatus` has a value of 1 until `rx_digitalreset` is deasserted or `rx_enapatternalign` is set to 1. `rx_patterndetect` has a value of 1 whenever a word alignment pattern is found for one parallel clock cycle regardless of whether or not the word aligner is triggered to align to the new word boundary.
Double Width	20 bits	

Programmable Run-Length Violation Detection

The programmable run-length violation detection circuit detects if the number of consecutive 1s or 0s in the received data exceeds the user-specified threshold.

Table 1-27: Detection Capabilities of the Run-Length Violation Circuit

PCS Mode	PMA–PCS Interface Width (bits)	Run-Length Violation Detector Range	
		Minimum	Maximum
Single Width	8	4	128
	10	5	160
Double Width	16	8	512
	20	10	640

Receiver Polarity Inversion

The positive and negative signals of a serial differential link might erroneously be swapped during board layout. Solutions such as board re-spin or major updates to the PLD logic can be expensive. The polarity inversion feature at the receiver corrects the swapped signal error without requiring board re-spin or major updates to the logic in the FPGA fabric. The polarity inversion feature inverts the polarity of every bit at the input to the word aligner, which has the same effect as swapping the positive and negative signals of the serial differential link.

Inversion is controlled dynamically with the `rx_invpolarity` register. When you enable the polarity inversion feature, initial disparity errors may occur at the receiver with the 8B/10B-coded data. The receiver must be able to tolerate these disparity errors.

Caution: If you enable polarity inversion midway through a word, the word will be corrupted.

Bit Reversal

You can reverse the bit order at the output of the word aligner for receiving a MSB-to-LSB transmission using the bit reversal feature at the receiver.

Table 1-28: Bit Reversal Feature

	Transmission Bit Order	
Bit Reversal Option	8- or 10-bit Serialization Factor	16- or 20-bit Serialization Factor
Disabled (default)	LSB to MSB	LSB to MSB
Enabled	MSB to LSB For example: 8-bit—`D[7:0]` rewired to `D[0:7]` 10-bit—`D[9:0]` rewired to `D[0:9]`	MSB to LSB For example: 16-bit—`D[15:0]` rewired to `D[0:15]` 20-bit—`D[19:0]` rewired to `D[0:19]`

Note: When receiving the MSB-to-LSB transmission, the word aligner receives the data in reverse order. The word alignment pattern must be reversed accordingly to match the MSB-first incoming data ordering.

You can dynamically control the bit reversal feature using the `rx_bitreversal_enable` register with the word aligner in bit-slip mode. When you dynamically enable the bit reversal feature in bit-slip mode, you can ignore the pattern detection function in the word aligner because the word alignment pattern cannot be dynamically reversed to match the MSB-first incoming data ordering.

Receiver Byte Reversal

The two symbols of incoming data at the receiver in double-width mode may be accidentally swapped during transmission.

For a 16-bit input data width at the word aligner, the two symbols are `bits[15:8]` and `bits[7:0]`. For a 20-bit input data width at the word aligner, the two symbols are `bits[19:10]` and `bits[9:0]`. The byte

reversal feature at the word aligner output can correct this error by swapping the two symbols in double-width mode at the word aligner output.

Table 1-29: Byte Reversal Feature

Byte Reversal Option	Word Aligner Output	
	16-bit Data Width	20-bit Data Width
Disabled	`D[15:0]`	`D[19:0]`
Enabled	`D[7:0], D[15:8]`	`D[9:0], D[19:10]`

The reversal is controlled dynamically using the `rx_bytereversal_enable` register. Enabling the byte reversal option may cause initial disparity errors at the receiver with 8B/10B-coded data. The receiver must be able to tolerate these disparity errors.

Note: When receiving swapped symbols, the word alignment pattern must be byte-reversed to match the incoming byte-reversed data.

Rate Match FIFO

The Rate Match FIFO compensates for the small clock frequency differences between the upstream transmitter and the local receiver clocks.

In a link where the upstream transmitter and local receiver can be clocked with independent reference clock sources, the data can be corrupted by any frequency differences (in ppm count) when crossing the data from the recovered clock domain—the same clock domain as the upstream transmitter reference clock—to the local receiver reference clock domain.

The rate match FIFO is 20 words deep, which compensates for the small clock frequency differences of up to ±300 ppm (600 ppm total) between the upstream transmitter and the local receiver clocks by performing symbol insertion or deletion, depending on the ppm difference on the clocks.

The rate match FIFO operation requires that the transceiver channel is in duplex configuration (both transmit and receive functions) and a predefined 20-bit pattern (consisting of a 10-bit control pattern and a 10-bit skip pattern). The 10-bit skip pattern must be chosen from a code group with neutral disparity.

The FIFO operates by looking for the 10-bit control pattern, followed by the 10-bit skip pattern in the data after the word aligner has restored the word boundary. After finding the pattern, the FIFO performs the following operations to ensure the FIFO does not underflow or overflow:

- Inserts the 10-bit skip pattern when the local receiver reference clock frequency is greater than the upstream transmitter reference clock frequency
- Deletes the 10-bit skip pattern when the local receiver reference clock frequency is less than the upstream transmitter reference clock frequency

The rate match FIFO supports operations in single- and double-width modes. You can define the 20-bit pattern for custom configurations. For protocol configurations, the FIFO is automatically configured to support a clock rate compensation function as required by the following specifications:

- The PCIe protocol per clock tolerance compensation requirement, as specified in the PCI Express Base Specification 2.0 for Gen1 and Gen2 signaling rates and PCI Express Base Specification 3.0 for Gen1, Gen2, and Gen3 signaling rates (Arria V GZ only).
- The Gbps Ethernet (GbE) protocol per clock rate compensation requirement using an idle ordered set, as specified in Clause 36 of the IEEE 802.3 specification

Note: For the Gigabit Ethernet protocol, if you enabled rate match FIFO in the autonegotiation state machine in an FPGA core, refer to the "Rate Match FIFO" section in the "Gigabit Ethernet" section in the *Transceiver Protocol Configurations in Arria V Devices* chapter.

Related Information

  For more information about the rate match FIFO operation in protocol-specific configurations.

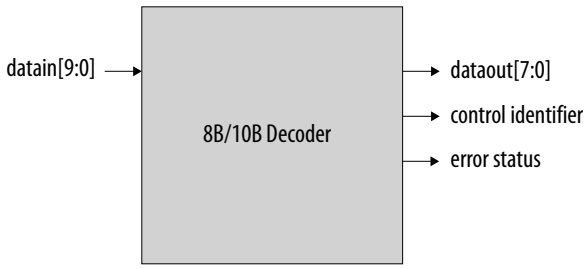
8B/10B Decoder

The 8B/10B decoder supports operation in single- and double-width modes.

8B/10B Decoder in Single-Width Mode

In single-width mode, the 8B/10B decoder decodes the received 10-bit code groups into an 8-bit data and a 1-bit control identifier in compliance with Clause 36 in the IEEE 802.3 specification. The 1-bit control identifier indicates if the decoded 8-bit code is a valid data or special control code.

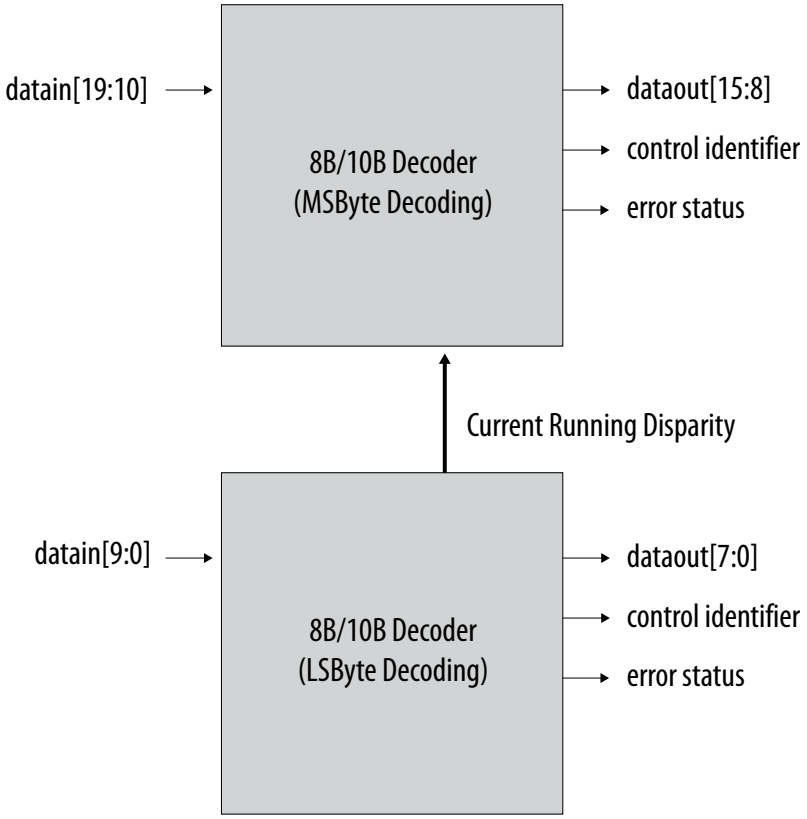
Figure 1-30: 8B/10B Decoder Block Diagram in Single-Width Mode



8B/10B Decoder in Double-Width Mode

In double-width mode, two 8B/10B decoders are cascaded to decode the 20-bit code groups into two sets of 8-bit data and two 1-bit control identifiers. When receiving the 20-bit code group, the 10-bit LSByte is decoded first and the ending running disparity is forwarded to the other 8B/10B decoder for decoding the 10-bit MSByte.

Figure 1-31: 8B/10B Decoder Block Diagram in Double-Width Mode



Byte Deserializer

The byte deserializer allows the receiver channel to operate at higher data rates in a configuration that exceeds the FPGA fabric–transceiver interface frequency limit.

The byte deserializer supports operation in single- and double-width modes. The datapath clock rate at the input of the byte deserializer is twice the FPGA fabric–receiver interface clock frequency.

Note: You must use the byte deserializer in configurations that exceed the maximum frequency limit of the FPGA fabric–transceiver interface.

After byte deserialization, the word alignment pattern may be ordered in the MSByte or LSByte position.

Table 1-30: Byte Deserializer Input Datapath Width Conversion

Data is assumed to be received as LSByte first—the least significant 8 or 10 bits in single-width mode or the least significant 16 or 20 bits in double-width mode.

Mode	Byte Deserializer Input Datapath Width	Receiver Output Datapath Width
Single Width	8	16
	10	20

Mode	Byte Deserializer Input Datapath Width	Receiver Output Datapath Width
Double Width	16	32
	20	40

Byte Ordering

When you enable the byte deserializer, the output byte order may not match the originally transmitted ordering. For applications that require a specific pattern to be ordered at the LSByte position of the data, byte ordering can restore the proper byte order of the byte-deserialized data before forwarding it to the FPGA fabric.

Byte ordering operates by inserting a predefined pad pattern to the byte-deserialized data if the predefined byte ordering pattern found is not in the LSByte position.

Byte ordering requires the following:

- A receiver with the byte deserializer enabled
- A predefined byte ordering pattern that must be ordered at the LSByte position of the data
- A predefined pad

Byte ordering supports operation in single- and double-width modes. Both modes support operation in word aligner-based and manual ordering modes.

Byte Ordering in Single-Width Mode

Byte ordering is supported only when you enable the byte deserializer.

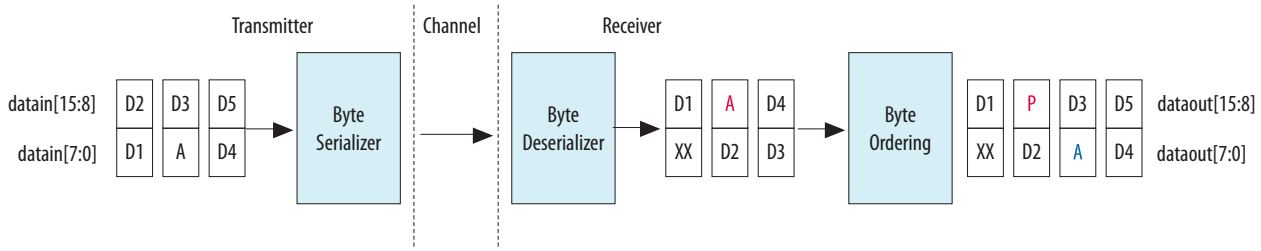
Table 1-31: Byte Ordering Operation in Single-Width Mode

PMA–PCS Interface Width	FPGA Fabric–Transceiver Interface Width	8B/10B Decoder	Byte Ordering Pattern Length	Pad Pattern Length
8 bits	16 bits	Disabled	8 bits	8 bits
10 bits	16 bits	Enabled	9 bits[8]	9 bits [8]
	20 bits	Disabled	10 bits	10 bits

[8] The MSB of the 9-bit pattern represents the 1-bit control identifier of the 8B/10B-decoded data. The lower 8 bits represent the 8-bit decoded code.

Figure 1-32: Byte Ordering Operation Example in Single-Width Mode

An example of a byte ordering operation in single-width mode (8-bit PMA-PCS interface width) where A is the predefined byte ordering pattern and P is the predefined pad pattern.



Byte Ordering in Double-Width Mode

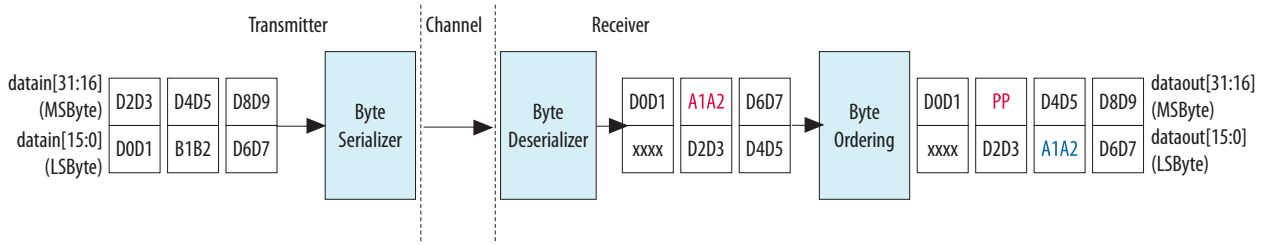
Byte ordering is supported only when you enable the byte deserializer.

Table 1-32: Byte Ordering Operation in Double-Width Mode

PMA–PCS Interface Width	FPGA Fabric–Transceiver Interface Width	8B/10B Decoder	Byte Ordering Pattern Length	Pad Pattern Length
16 bits	32 bits	Disabled	8 or 16 bits	8 bits
20 bits	32 bits	Enabled	9[9] or 18 bits[10]	9 bits[9]
	40 bits	Disabled	10 or 20 bits	10 bits

Figure 1-33: Byte Ordering Operation Example in Double-Width Mode

An example of a byte ordering operation in double-width mode (16-bit PMA-PCS interface width) where A1A2 is the predefined byte ordering pattern and P is the predefined pad pattern.



Word Aligner-Based Ordering Mode

In word aligner-based ordering mode, the byte ordering operation is controlled by the word aligner synchronization status signal, `rx_syncstatus`.

After a rising edge on the `rx_syncstatus` signal, byte ordering looks for the byte ordering pattern in the byte-deserialized data.

(9) The MSB of the 9-bit pattern represents the 1-bit control identifier of the 8B/10B-decoded data. The lower 8 bits represent the 8-bit decoded code.

(10) The 18-bit pattern consists of two sets of 9-bit patterns, individually represented as in the previous note.

When the first data byte that matches the byte ordering pattern is found, the byte ordering performs the following operations:

- If the pattern is not in the LSByte position—byte ordering inserts the appropriate number of pad patterns to push the byte ordering pattern to the LSByte position and indicates the byte alignment.
- If the pattern is in the LSByte position—byte ordering indicates the byte alignment.

Any byte misalignment found thereafter is ignored unless another rising edge on the `rx_syncstatus` signal, indicating resynchronization, is observed.

Manual Ordering Mode

In manual ordering mode, the byte ordering operation is controlled using the `rx_enabyteord` signal.

A rising edge on the `rx_enabyteord` signal triggers byte ordering to look for the byte ordering pattern in the byte-deserialized data.

When the first data byte that matches the byte ordering pattern is found, the byte ordering performs the following operations:

- If the pattern is not in the LSByte position—byte ordering inserts the appropriate number of pad patterns to push the byte ordering pattern to the LSByte position and indicates the byte alignment.
- If the pattern is in the LSByte position—byte ordering indicates the byte alignment.

Any byte misalignment found thereafter is ignored unless another rising edge on the `rx_enabyteord` signal is observed.

Receiver Phase Compensation FIFO

The receiver phase compensation FIFO is four words deep and interfaces the status and data signals between the receiver PCS and the FPGA fabric or the PCIe hard IP block. The FIFO supports the following operations:

- Phase compensation mode with various clocking modes on the read clock and write clock
- Registered mode with only one clock cycle of datapath latency

Phase Compensation Mode

The receiver phase compensation FIFO compensates for any phase difference between the read and write clocks for the receiver status and data signals.

The low-speed parallel clock feeds the write clock; the FPGA fabric interface clock feeds the read clock. The clocks must have 0 ppm difference in frequency or a FIFO underrun or overflow condition may result.

The receiver phase compensation FIFO supports various clocking modes on the read and write clocks depending on the transceiver configuration.

Related Information

For a detailed description of the receiver datapath interface clocking modes when using the receiver phase compensation FIFO, seeTransceiver Clocking in Arria V Devices.

Registered Mode

To eliminate the FIFO latency uncertainty for applications with stringent datapath latency uncertainty requirements, bypass the FIFO functionality in registered mode to incur only one clock cycle of datapath

latency when interfacing the receiver channel to the FPGA fabric. Configure the FIFO to registered mode when interfacing the receiver channel to the PCIe hard IP block to reduce datapath latency. In registered mode, the low-speed parallel clock that is used in the receiver PCS clocks the FIFO.

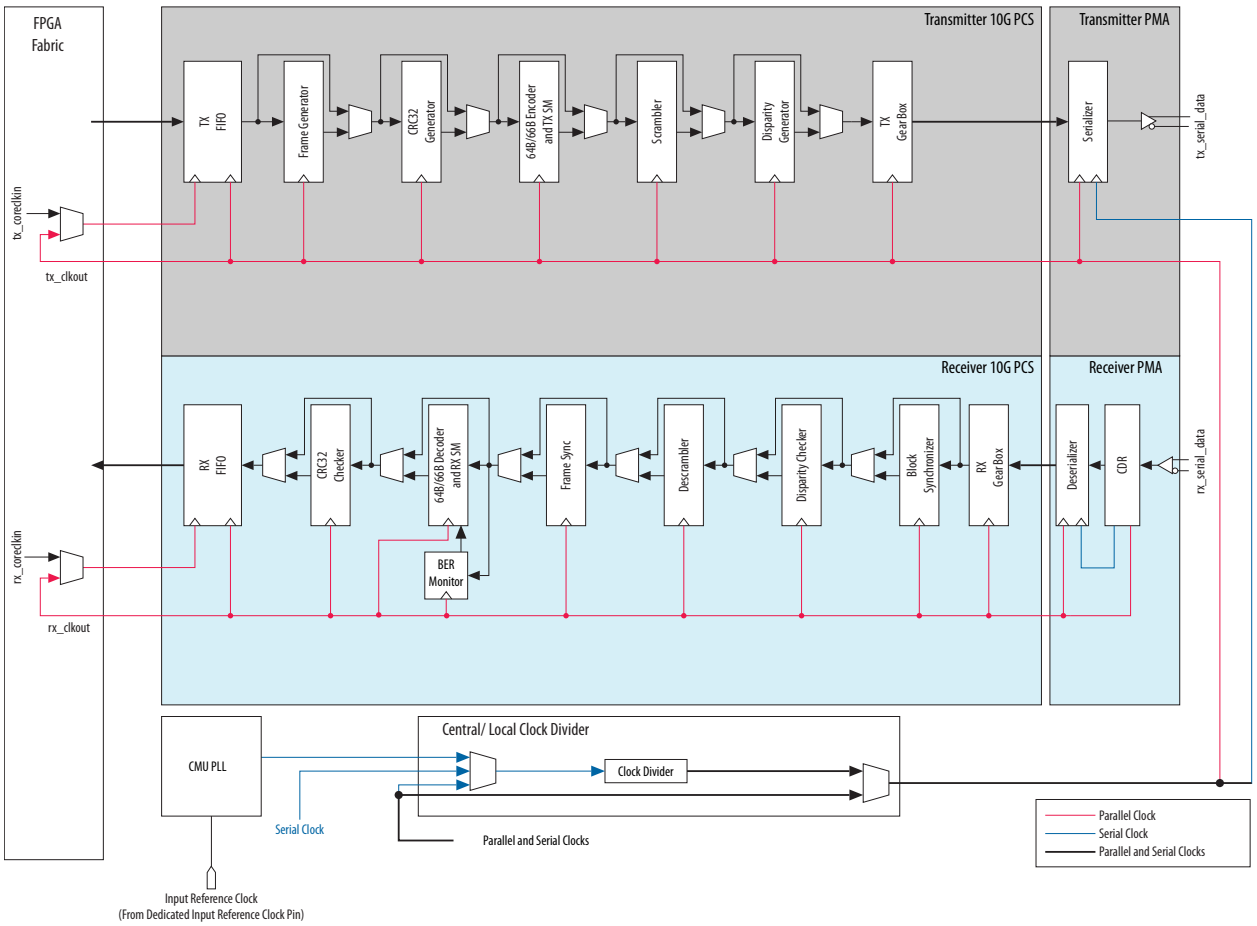
10G PCS Architecture for Arria V GZ Devices

The 10G PCS architecture offers a full duplex (transmitter and receiver) transceiver channel that supports serial data rates up to 12.5 Gbps for Arria V GZ devices.

Several functional blocks are customized for various protocols. The different datapath configurations for these protocols are available through the different PHY IPs instantiated through the Parameter Editor. Currently, the only supported configurations for the 10G PCS are Interlaken, 10GBASE-R and low-latency 10G PCS.

Figure 1-34: 10G PCS Datapath in Arria V GZ Channels

Not all the blocks shown in the 10G PCS datapath are available in every configuration.



Related Information

Altera Transceiver PHY IP Core User Guide

Transmitter 10G PCS Datapath

The sub-blocks in the transmitter 10G PCS datapath are described in order from the transmitter FIFO to the transmitter gearbox.

Transmitter FIFO

The transmitter FIFO provides an interface between the transmitter channel PCS and the FPGA fabric.

In 10GBASE-R configurations, the transmitter FIFO receives data from the FPGA fabric. The data output from the transmitter FIFO block goes to the 64B/66B encoder.

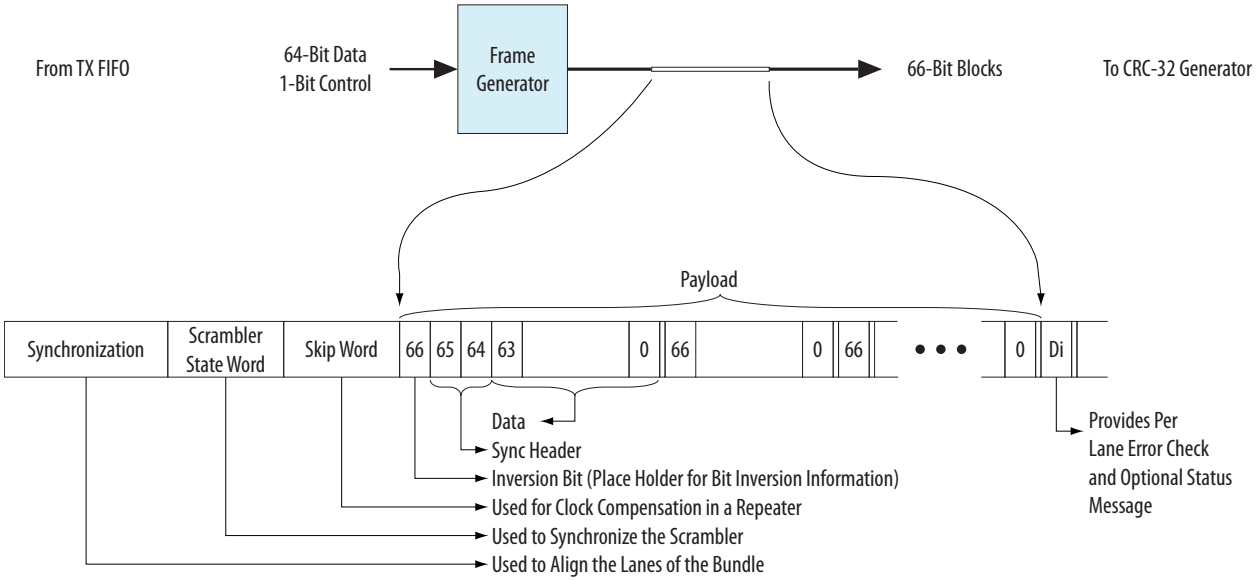
In Interlaken configurations, the transmitter FIFO sends a control signal to indicate whether it is ready to receive data from the FPGA fabric. The user logic sends the data to the transmitter FIFO only if this control signal is asserted. In this configuration, data output from the transmitter FIFO block goes to the frame generator.

Frame Generator

The frame generator block supports the Interlaken protocol. The frame generator block takes the data from the transmitter FIFO and encapsulates the payload and burst/idle control words from the FPGA fabric with the framing layer's control words, such as the synchronization word, scrambler state word, skip word, and diagnostic word, to form a metaframe. The Interlaken PHY IP core Parameter Editor allows you to set the metaframe length.

Note: The frame generator is used only in Interlaken configurations.

Figure 1-35: Frame Generator



CRC-32 Generator

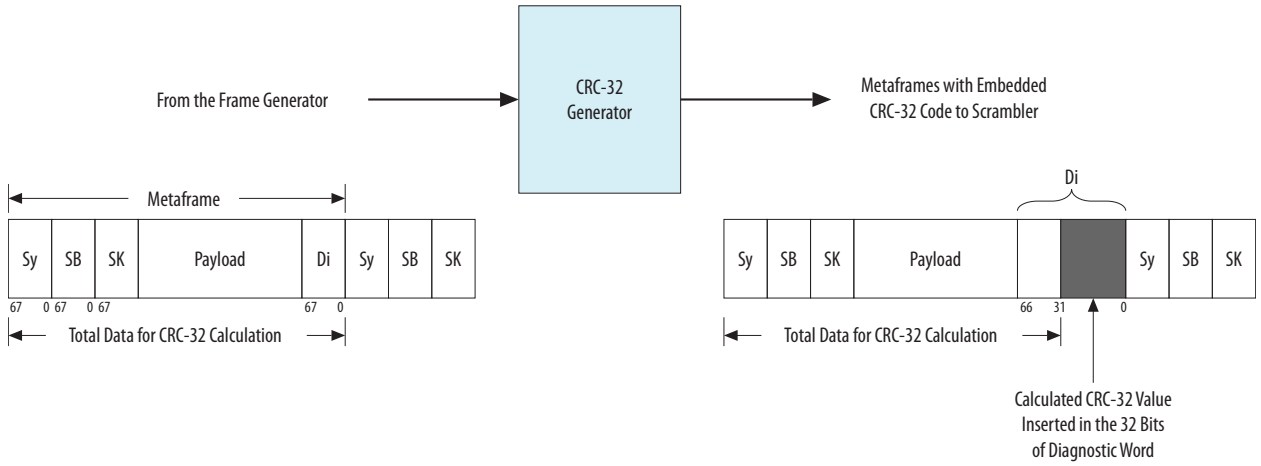
The CRC-32 generator block receives data from the frame generator and calculates the cyclic redundancy check (CRC) code for each block of data. This CRC code value is stored in the CRC32 field of the diagnostic word.

Note: The CRC-32 generator is used only in Interlaken configurations.

The CRC-32 calculation covers most of the metaframe, including the diagnostic word, except the following:

- bits [66:64] of each word
- 58-bit scrambler state within the scrambler state word
- 32-bit CRC-32 field within the diagnostic word

Figure 1-36: CRC-32 Generator



64B/66B Encoder

The 64B/66B encoder conforms to the 10GBASE-R protocol specification as described in IEEE 802.3-2008 clause-49.

Note: The 64B/66B encoder is used only in 10GBASE-R configurations.

This block contains the 64B/66B encoder sub-block and the transmitter state machine sub-block. The 64B/66B encoder sub-block receives data from the transmitter FIFO and encodes the 64-bit data and 8-bit control characters to the 66-bit data block required by the 10GBASE-R configuration. The transmit state machine in the 64B/66B encoder sub-block checks the validity of the 64-bit data from the MAC layer and ensures proper block sequencing.

Scrambler

The scrambler operates in frame synchronous mode and self synchronous mode. Frame synchronous mode operates in Interlaken configurations. Self synchronous mode operates in 10GBASE-R configurations, as specified in IEEE 802.3-2008 clause-49.

Disparity Generator

The disparity generator block conforms to the Interlaken protocol specification and provides a DC-balanced data output. The disparity generator receives data from the scrambler and inverts the running disparity to stay within the ±96-bit boundary. To ensure this running disparity requirement, the disparity generator inverts bits [63:0] and sets bit [66] to indicate the inversion.

Note: The disparity generator is used only in Interlaken configurations.

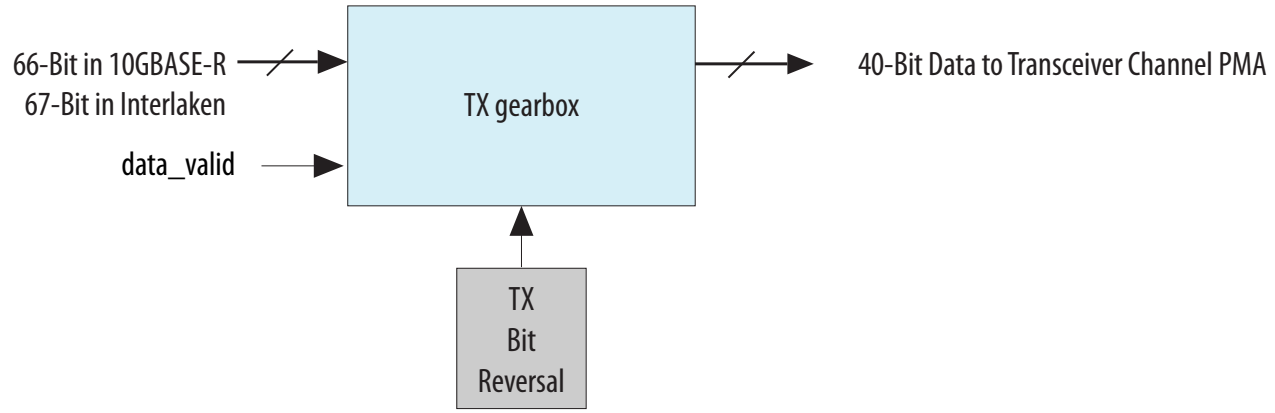
Table 1-33: Interpretation of the MSB in the 67-Bit Payload for Arria V Devices

MSB	Interpretation
0	Bits [63:0] are not inverted; the disparity generator processes the word without modification
1	Bits [63:0] are inverted; the disparity generator inverts the word before processing it

Transmitter Gearbox

The transmitter gearbox adapts the PCS data width to a smaller bus width for interfacing with the PMA. Because of the transmitter gearbox, the difference in the bus widths between the PCS and the PMA is transparent to the logic in the FPGA fabric.

Figure 1-37: Transmitter Gearbox



In addition to providing bus width adaptation, the transmitter gearbox provides the transmitter polarity inversion, bit reversal and bit-slip features.

Transmitter Bit Reversal

The transmitter gearbox can reverse the order of transmitted bits. By default, the transmitter first sends out the LSB of a word. Some protocols, such as Interlaken, require that the MSB of a word (bit 66 in a word [66:0]) is transmitted first. When you enable the transmitter bit reversal, the parallel input to the gearbox is swapped and the MSB is sent out first. The Quartus® II software automatically sets the bit reversal for Interlaken configurations.

Transmitter Polarity Inversion

Transmitter polarity can be used to reverse the positive and negative differential buffer signals. This is useful if these signals are reversed on the board or backplane layout.

A high value on the tx_invpolarity register, which is accessed via the Avalon-MM PHY management interface, inverts the polarity of every bit of the input data word to the serializer in the transmitter datapath. Because inverting the polarity of each bit has the same effect as swapping the positive and negative signals of the differential link, correct data is sent to the receiver. Dynamically changing the tx_invpolarity register value might cause initial disparity errors at the receiver of an 8B/10B encoded link. The downstream system must be able to tolerate these disparity errors.

If polarity inversion is asserted midway through a serializer word, the word will be corrupted.

Transmitter Bit-Slip

The transmitter bit-slip allows you to compensate for the channel-to-channel skew between multiple transmitter channels by slipping the data sent to the PMA. The maximum number of bits slipped is controlled from the FPGA fabric and is equal to the width of the PMA-PCS interface, minus one.

Receiver 10G PCS Datapath

The sub-blocks in the receiver 10G PCS datapath are described in order from the receiver gearbox to the receiver FIFO.

Receiver Gearbox

The receiver gearbox adapts the PMA data width to a larger bus width to interface with the PCS. The PMA bus width is smaller than the PCS bus width; therefore, the receiver gearbox expands the data bus width from the PMA to the PCS. Because bus width adaptation is transparent, you can continuously feed data to the receiver gearbox. In addition to providing bus width adaptation, the receiver gearbox provides the receiver bit reversal feature.

Receiver Polarity Inversion

The receiver gearbox can invert the polarity of the incoming data. This is useful if the receive signals are reversed on the board or backplane layout.

Receiver Bit Reversal

The receiver gearbox allows bit reversal of the received data. Some protocols, such as Interlaken, require the bit reversal feature.

Related Information

Transmitter Bit Reversal on page 1-57

Block Synchronizer

The block synchronizer determines the block boundary of a 66-bit word in the case of the 10GBASE-R protocol or a 67-bit word in the case of the Interlaken protocol. The incoming data stream is slipped one bit at a time until a valid synchronization header (bits 65 and 66) is detected in the received data stream. After the predefined number of synchronization headers (as required by the protocol specification) is detected, the block synchronizer asserts the status signal to other receiver PCS blocks down the receiver datapath and to the FPGA fabric.

The block synchronizer is designed in accordance with both the Interlaken protocol specification and the 10GBASE-R protocol specification as described in IEEE 802.3-2008 clause-49.

Disparity Checker

The design of the disparity checker is based on the Interlaken protocol specifications. After word synchronization is achieved, the disparity checker monitors the status of the 67th bit of the incoming word and determines whether or not to invert bits [63:0] of the received word.

Note: The disparity checker is only used in Interlaken configurations.

Table 1-34: Interpretation of the MSB in the 67-Bit Payload for Arria V Devices

MSB	Interpretation
0	Bits [63:0] are not inverted; the disparity checker processes the word without modification
1	Bits [63:0] are inverted; the disparity checker inverts the word to achieve the original word before processing it

Descrambler

The descrambler descrambles data per the protocol specifications supported by the 10G PCS. The descrambler operates either in frame synchronous or self synchronous mode.

Frame Synchronous Mode

Frame synchronous mode is used in Interlaken configurations only. When block synchronization is achieved, the descrambler uses the scrambler seed from the received scrambler state word. This block also forwards the current descrambler state to the frame synchronizer.

Self Synchronous Mode

Self synchronous mode is used in 10GBASE-R configurations only.

Frame Synchronizer

The frame synchronizer block achieves lock by looking for four synchronization words in consecutive metaframes. After synchronization, the frame synchronizer monitors the scrambler word in the metaframe and deasserts the lock signal after three consecutive mismatches and starts the synchronization process again. Lock status is available to the FPGA fabric.

Note: The frame synchronizer is only used in Interlaken configurations.

Bit-Error Rate (BER) Monitor

The BER monitor block conforms to the 10GBASE-R protocol specification as described in IEEE 802.3-2008 clause-49. After block lock is achieved, the BER monitor starts to count the number of invalid synchronization headers within a 125-ms period. If more than 16 invalid synchronization headers are observed in a 125-ms period, the BER monitor provides the status signal to the FPGA fabric, indicating a high bit error rate condition.

64B/66B Decoder

The 64B/66B decoder block contains a 64B/66B decoder sub-block and a receiver state machine sub-block. The 64B/66B decoder sub-block converts the received data from the descrambler into 64-bit data and 8-bit control characters. The receiver state machine sub-block monitors the status signal from the BER monitor. If the status signal is asserted, the receiver state machine sends local fault ordered sets to the FPGA interface.

Note: The 64B/66B encoder is used only in 10GBASE-R configurations.

The 64B/66B decoder block is designed towards the 10GBASE-R protocol specification as described in IEEE 802.3-2008 clause-49.

CRC-32 Checker

The CRC-32 checker block supports the Interlaken protocol. The CRC-32 checker calculates the CRC from the incoming data and compares the result to the CRC value sent in the diagnostic word. The CRC error signal is sent to the FPGA fabric.

Receiver FIFO

The receiver FIFO block operates in different modes based on the transceiver datapath configuration.

The Quartus II software automatically selects receiver FIFO mode for the configuration you use.

Clock Compensation Mode

The receiver FIFO is configured in clock compensation mode for the 10GBASE-R configuration. In clock compensation mode, the FIFO deletes idles or ordered sets and inserts only idles to compensate up to a ±100 ppm clock difference between the remote transmitter and the local receiver.

Generic Mode

The receiver FIFO is configured in generic mode for the Interlaken configuration. In generic mode, the receiver FIFO provides the FIFO partially empty and FIFO full status signals to the FPGA fabric to control the read side of the FIFO.

Phase Compensation Mode

The receiver FIFO is configured in phase compensation mode for the 10G custom configuration. In phase compensation mode, the FIFO compensates for the phase difference between the FIFO write clock and the read clock.

XAUI Mode

In XAUI mode, the receiver FIFO compensates for up to ±100 ppm (200 ppm total) difference between the upstream transmitter and the local receiver reference clock. The XAUI protocol requires the transmitter to send /R/ (/K28.0/) code groups simultaneously on all four lanes (denoted as ||R|| column) during inter-packet gaps (IPGs), conforming to the IEEE P802.3ae specification. The receiver FIFO operation in XAUI mode is compliant with the IEEE P802.3ae specification.

PCIe Mode

In PCIe mode, the receiver FIFO compensates for up to ±300 ppm (total 600 ppm) difference between the upstream transmitter and the local receiver. The PCIe protocol requires the transmitter to send SKP ordered sets during IPGs, conforming to the PCIe base specification 2.0. The SKP ordered set is defined as a /K28.5/ COM symbol followed by three consecutive /K28.0/ SKP symbol groups.

The PCIe protocol requires the receiver to recognize a SKP ordered set as a /K28.5/ COM symbol followed by one to five consecutive /K28.0/ SKP symbols. The rate match FIFO operation is compliant with PCIe Base Specification 2.0.

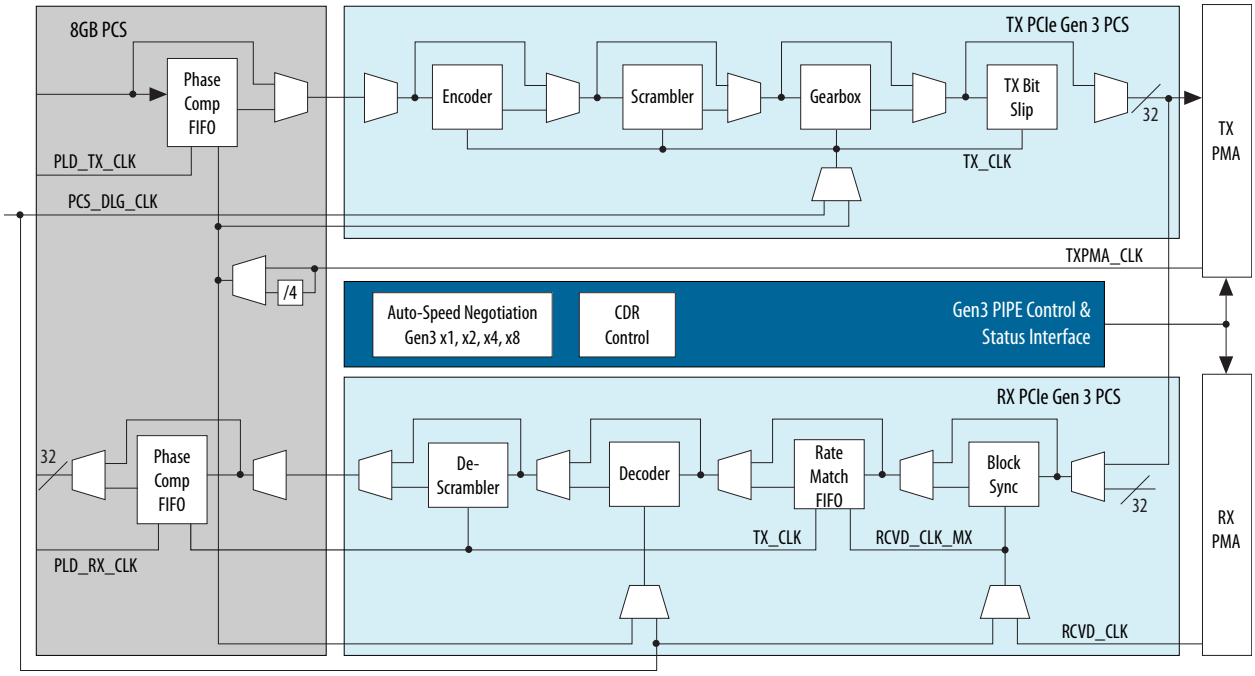
PCIe Gen3 PCS Architecture

Arria V supports the PCIe Gen3 Base specification. The PCIe Gen3 uses a 128/130 bit block encoding/decoding scheme which is different from the 8B/10B scheme used in Gen1 and Gen2. The 130-bit block contains a 2-bit sync header and 128-bit data payload. For this reason, the PCIe Gen3 PCS has a separate data path as compared to the PCIe Gen1 or Gen2 PCS. The PCIe Gen3 PCS supports the PHY Interface for the PCI Express (PIPE) interface with the hard IP enabled and with the hard IP bypassed.

This PIPE interface supports the seamless switching of Data and Clock between the Gen1, Gen2, and Gen3 PCS, and provides support for PIPE 3.0 features.

The overall simplified PCIe Gen3 PCS the following architecture diagram. Note that the RX/TX Phase Comp FIFOs are physically placed in, and shared with the standard 8GB PCS.

Figure 1-38: PCIe Gen3 PCS Top Level Block Diagram



Transmitter PCIe Gen3 PCS Datapath

This section describes the transmitter channel PCIe Gen3 PCS datapath architecture.

Phase Compensation FIFO (Shared with Standard PCS)

Related Information

Transmitter Phase Compensation FIFO on page 1-33

Scrambler

The Scrambler is an additive scrambler on a per-lane basis with degree 23 polynomial linear feedback shift register (LFSR), with different taps for the 8 adjacent lanes. The scrambler is used to provide enough edge density, since there is no 8B/10B encoding in PCIe Gen 3, so that the RX PMA CDR can lock to the incoming data stream and generate the recovered clock.

Encoder

The PCIe Gen 3 base specification defines that the data packets have to be scrambled and descrambled, whereas the Ordered Set packets (except the first symbol of TS1 and TS2 Ordered Set) do not have to be scrambled or descrambled. The Encoder/Decoder continuously checks the header and payload of the packet and generates a signal to enable the scrambler/descrambler based upon whether the payload is an ordered set, or data packet. It also generates a signal to reset the scrambler/descrambler to the initial seed value if an Electrical Idle Exit Ordered Set or a Fast Training Sequence Ordered Set is received or

transmitted. In addition, the encoder/decoder logic monitors the Ordered Set and the header for invalid values, and generates an error flag if they do.

Gearbox

The PCIe 3.0 base specification specifies a block size of 130 bits, with the exception of SKP Ordered Sets which can be variable length. An implementation of a 130-bit data path would take up significant resources, so the PCIe Gen 3 PCS data path is implemented as 32 bits wide. As the TX PMA data width is fixed to 32 bits, and the block size is 130 bits with variations, a gearbox is needed to convert the 130 bits to 32 bits. This gearbox has a transmitter bit-slip feature.

Receiver PCIe Gen3 PCS Datapath

This section describes the receiver channel PCIe Gen3 PCS datapath architecture.

Block Sync

PMA parallelization occurs at arbitrary word boundaries. Consequently, the parallel data from the RX PMA CDR must be realigned to meaningful character boundaries. The Block Sync module searches for the Electrical Idle Exit Sequence Ordered Set (or the last number of fast training sequences (NFTS) Ordered Set) and skip (SKP) Ordered Set to identify the correct boundary for the incoming stream and achieve the block alignment. The block is realigned to the new block boundary following the receipt of a SKP Ordered Set, as it can be of variable length.

Rate Match FIFO

The Rate Match FIFO (or clock compensation FIFO) compensates for minute frequency differences between the local clock (sometimes referred to as PLD soft IP clock, or PLD system clock) and the recovered clock. This is achieved by inserting and deleting SKP characters in the data stream to keep the FIFO from going empty or full respectively.

Decoder

The Decoder checks for decode errors in the data stream. It also enables or disables the Descrambler based on the Data and Ordered Set received.

Descrambler

The Descrambler descrambles data per the PCIe Gen3 specification.

PIPE Interface

The PIPE Interface block provides PIPE Gen3 compliant control and status interfaces between the high-speed serial interface (HSSI) and upper layer logic. It is PIPE 3.0 compliant.

Auto Speed Negotiation Block

The Auto Speed Negotiation block controls the operating speed of the HSSI when operating under PIPE 3.0 modes. By monitoring the rate control signal from the PhyMac, this block will change the HSSI from PCIe Gen 1 operation mode, to Gen 2 operation mode, or from PCIe Gen 1 operation mode to Gen 2 operation mode to Gen 3 operation mode, or vice versa, with all the appropriate settings.

Electrical Idle Inference Block

In conjunction with side band signals from the PLD side, the Electrical Idle Inference Block infers Electrical Idle assuming that the signal detect is not reliable. This is based on the PCIe Base Specification Revision 2.0/3.0.

Clock Data Recovery (CDR) Control Block

The CDR control block is used for Rx.L0s fast exit when operating in PIPE/PCIe Gen 3 mode. Upon detecting an Electrical Idle Ordered Set (EIOS), it takes manual control of the CDR by forcing it into a lock to reference mode. When an exit from electrical idle is detected, this block moves the CDR into lock to data mode to achieve fast data lock.

Channel Bonding

The following factors contribute to the transmitter channel-to-channel skew:

- High-speed serial and low-speed parallel clock skew between channels
- Unequal latency in the transmitter phase compensation FIFO

Bonded transmitter datapath clocking provides low channel-to-channel skew when compared with non-bonded channel configurations.

Related Information

For more information about the bonded and non-bonded channel clocking, see Transceiver Clocking in Arria V Devices.

Bonded Channel Configurations

In bonded channel configurations, the serial and parallel clocks are generated by the transmit PLL and the central clock divider.

There is equal latency in the transmitter phase compensation FIFO of all bonded channels because they share common pointers and control logic generated in the central clock divider.

The lower transceiver clock skew and equal latency in the transmitter phase compensation FIFO in all channels result in a lower channel-to-channel skew.

Note: Bonded channel configurations are available only for serial data rates up to 6.5536 Gbps in Arria V GX/GT/SX/ST devices and up to 12.5 Gbps in Arria V GZ devices. You can bond (up to) all channels on the same side.

Non-Bonded Channel Configurations

In a non-bonded channel configuration, the parallel clock in each channel is generated independently by its local clock divider.

There may be unequal latency in the transmitter phase compensation FIFO of each channel because each channel has its own pointers and control logic. The higher transceiver clock skew and unequal latency in the transmitter phase compensation FIFO in each channel may result in a higher channel-to-channel skew.

PLL Sharing

In a Quartus II design, you can merge two different protocol configurations to share the same CMU PLL resources. These configurations must fit in the same transceiver bank. The input `refclk` and PLL output frequencies must be identical.

Document Revision History

The revision history for this chapter.

Table 1-35: Document Revision History

Date	Version	Changes
September 2014	2014.09.30	• Changed the *Transceiver Bank and PCIe Hard IP Location for GT Devices* figure to show Ch0 of GXB_L1 as a 10-Gbps channel. Also added notes to the figure. • Added an example calculation for the maximum supported data rate and a related link to the *Arria V Device Datasheet* in the *Transceiver Channel Architecture* section. • Added a description of `rx_syncstatus` to the *Word Aligner in Manual Alignment Mode* section. • Added a description of `rx_syncstatus` to the *Word Aligner in Deterministic Latency State Machine Mode* section. • Changed "MegaWizard Plug-in Manager" to "Parameter Editor" in the *10G PCS Architecture for Arria V GZ Devices* and *Frame Generator* sections.
March 2014	2014.03.07	• Updated Table 1-7. • Updated the *Transmitter Buffer* section. • Updated the *Word Aligner* section. • Updated the *Word Aligner in Deterministic Latency State Machine Mode* section. • Updated the *Clock Divider* section. • Updated Figure 1-28. • Added a note to the *Rate Match FIFO* section.
October 2013	2013.10.18	• Updated the *Transceiver Architecture in Arria V Devices* section. • Updated the *Enhanced Small Form-Factor Pluggable (SFP+) Interface* section. • Updated the *Channel PLL Architecture* section. • Updated Table 1-1. • Updated Table 1-6. • Updated Table 1-22.

Date	Version	Changes
May 2013	2013.05.06	• Added link to the known document issues in the Knowledge Base • Updated Figure 1-1. • Updated Table 1-6. • Updated the *Adaptive Equalization Mode* section. • Updated the *Transmitter Buffer* section. • Updated the *Receiver Buffer* section. • Updated the *Clock Divider* section. • Updated the *Word Aligner in Manual Alignment Mode* section. • Updated the *Bit Slip Mode* section. • Updated the *Auxiliary Transmit (ATX) PLL Architecture* section.
March 2013	2013.03.15	• Updated Figure 1-2. • Updated Figure 1-3, and clarified the data rate for rx-only channels. • Updated Figure 1-7, and clarified the data rate for rx-only channels. • Updated *Transceiver Banks* . • Added *10-Gbps Support Capability in GT and ST Devices*. • Added *Enhanced Small Form-Factor Pluggable (SFP+) Modules*. • Added *10GBase-KR Support*. • Added *9.8 Gbps CPRI Application*. • Added *Transceiver Channel Architecture*.
November 2012	2012.11.19	Reorganized content and updated template
June 2012	1.2	• Merged information from Transceiver Basics for Arria V Devices, version 1.1 into this chapter.

Transceiver Clocking in Arria V Devices

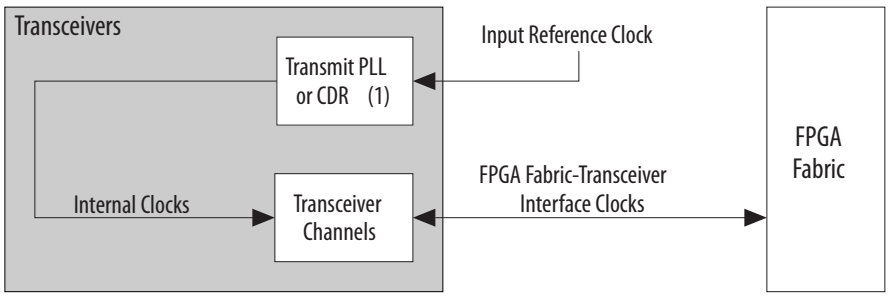
2

2015.03.17

AV53002 Subscribe Send Feedback

This chapter provides information about the Arria V transceiver clocking architecture. The chapter describes the clocks that are required for operation, internal clocking architecture, and clocking options when the transceiver interfaces with the FPGA fabric.

Figure 2-1: Transceiver Clocking Architecture Overview



Note: (1) The transmit phase-locked loop (PLL) can be a CMU PLL (channel PLL), fPLL (fractional PLL Clock) or an ATX PLL (for Arria V GZ devices only.)

Related Information

Arria V Device Handbook: Known Issues

Lists the planned updates to the *Arria V Device Handbook* chapters.

Input Reference Clocking

The reference clock for the transmitter PLL and CDR generates the clocks required for transceiver operation.

(11) ATX PLL is available only in Arria V GZ devices.

(12) The lower number indicates better jitter performance.

(13) Applicable for 10 Gbps channels only in GT and ST devices and for 12.5 Gbps channels in GZ devices. For better jitter performance, use dedicated refclk pins for data rates > 6.5536 Gbps.

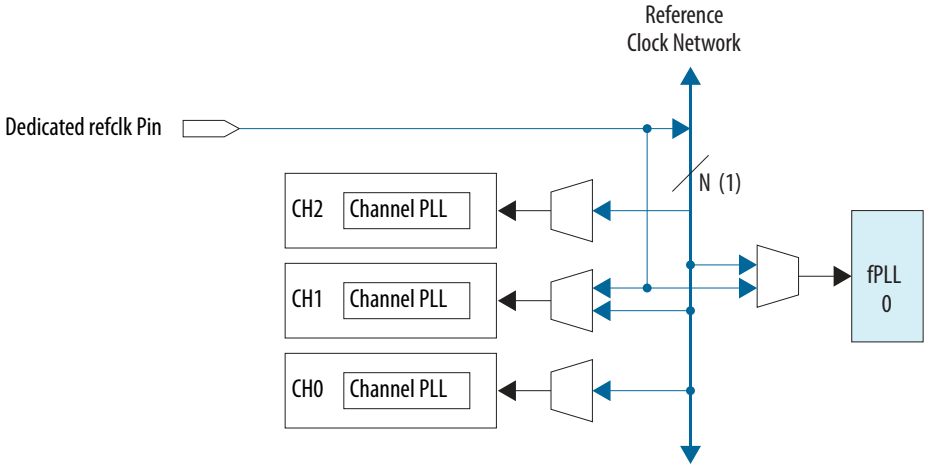
(14) For Arria V GZ devices, the dual-purpose RX/REFCLK pin can be used as a reference clock source for CMU PLL with data rates > 6.5536 Gbps.

Table 2-1: Input Reference Clock Sources

Sources	Transmitter PLL				CDR	Jitter Performance (12)
	ATX PLL (11)	CMU PLL > 6.5536 Gbps (13)	CMU PLL <= 6.5536 Gbps	fPLL		
Dedicated refclk pin	Yes	Yes	Yes	Yes	Yes	1
REFCLK network	Yes	Yes	Yes	Yes	Yes	2
Dual-purpose RX/REFCLK pin	Yes	No (14)	Yes	Yes	Yes	3
Fractional PLL	No	No	Yes	Yes	Yes	4
Generic CLK pin	No	No	No	No	No	5
Core clock network (GCLK, RCLK, PCLK)	No	No	No	No	No	6

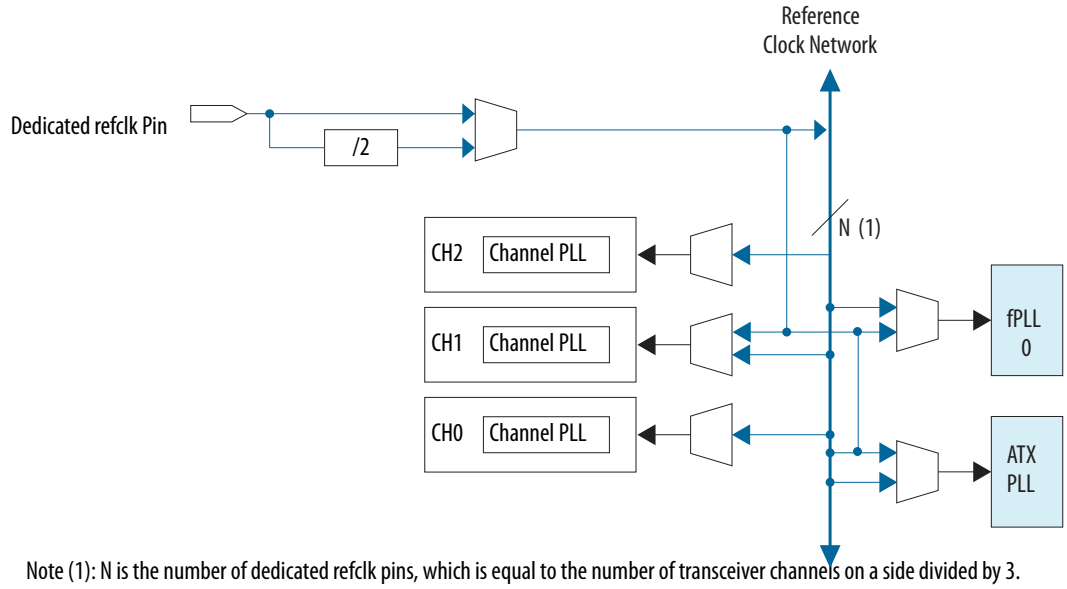
Figure 2-2: Dedicated refclk Pin and Reference Clock Network

The following figure shows the dedicated refclk pin connection to channel PLL. The direct refclk pin connection to channel PLL (which can either be configured as CMU PLL or CDR) is only available in channel 1 and 4 in a bank.



Note (1): N is the number of dedicated refclk pins, which is equal to the number of transceiver channels on a side divided by 3.

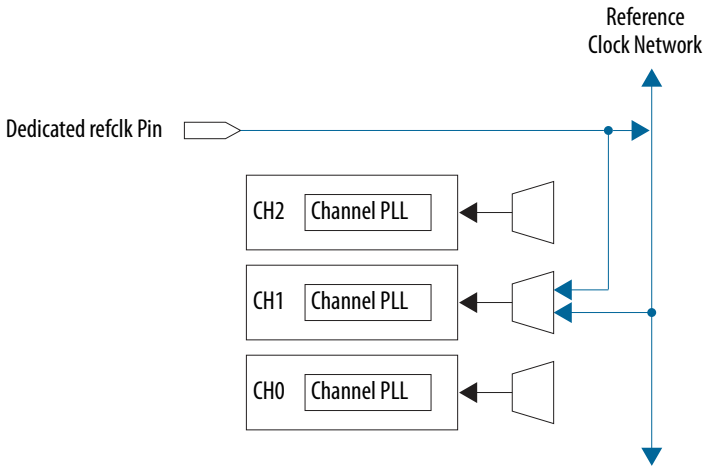
Figure 2-3: Dedicated refclk Pin and Reference Clock Network for Arria V GZ Devices



Note (1): N is the number of dedicated refclk pins, which is equal to the number of transceiver channels on a side divided by 3.

Note: ATX PLL is available only for Arria V GZ devices.

Figure 2-4: Input Reference Clock Source for CMU PLL Driving Channels with Serial Data Rates Beyond 6.5536 Gbps



(15) For more information about termination values supported, refer to the *DC Characteristics* section in *Arria V Device Datasheet*.

(16) In PCIe mode, you have the option of selecting the HCSL standard for the reference clock if compliance to the PCIe protocol is required. You can select this I/O standard option only if you have configured the transceiver in PCIe mode.

(17) For an example termination scheme refer to **Figure 2-5**

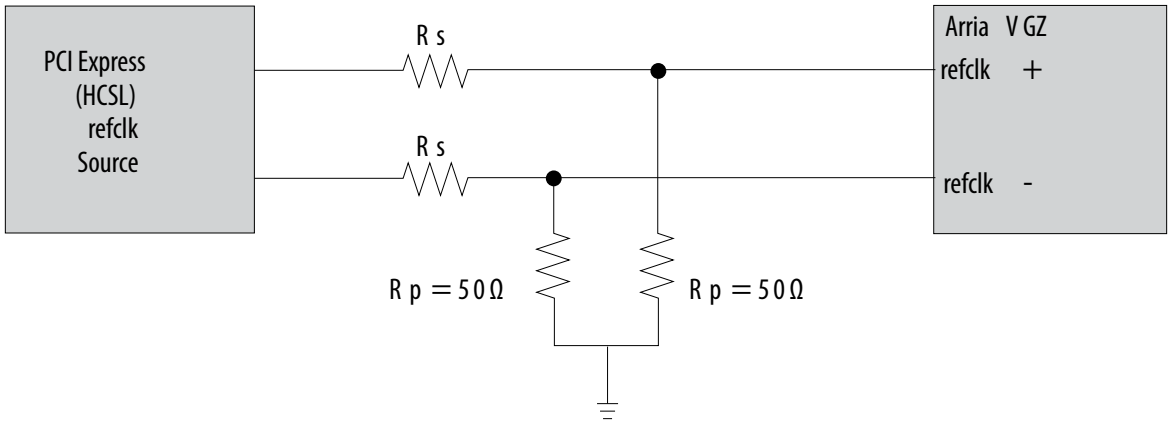
Table 2-2: Electrical Specifications for the Input Reference Clock for Arria V GZ Devices

Protocol	I/O Standard	Coupling	Termination
PCI Express (PCIe)	• 1.2V PCML, 1.4 PCML • 1.4V PCML • 1.5V PCML • 2.5V PCML • Differential LVPECL • LVDS	AC	On - Chip (15)
	• HCSL (16)	DC	Off - Chip (17)
All other protocols	• 1.2V PCML, 1.4 PCML • 1.4V PCML • 1.5V PCML • 2.5V PCML • Differential LVPECL • LVDS	AC	On - Chip (15)

Note: If you select the HCSL I/O standard for the PCIe reference clock, add the following assignment to your project's Quartus settings file (.qsf):

```
set_instance_assignment -name XCVR_REFCLK_PIN_TERMINA-
TION_DC_COUPLING_EXTERNAL_RESISTOR -to <refclk_pin_name>
```

Figure 2-5: Termination Scheme for a Reference Clock Signal When Configured as HCSL for Arria V GZ Devices



Note:
- No biasing is required if the reference clock signals are generated from a clock source that conforms to the PCIe specification.
- Select Rs and / or Rp resistor values as recommended by the PCIe clock source vendor.

Arria V Device Datasheet

Reference Clock Network

The dedicated refclk pin can provide the reference clock to multiple channel PLLs, fractional PLLs or an ATX PLL (for Arria V GZ devices).

Designs that use multiple transmitter PLL and CDRs with the same input reference clock frequency can share the same dedicated refclk pin. Each dedicated refclk pin can drive any transmitter PLL or CDR on the same side of device through the reference clock network.

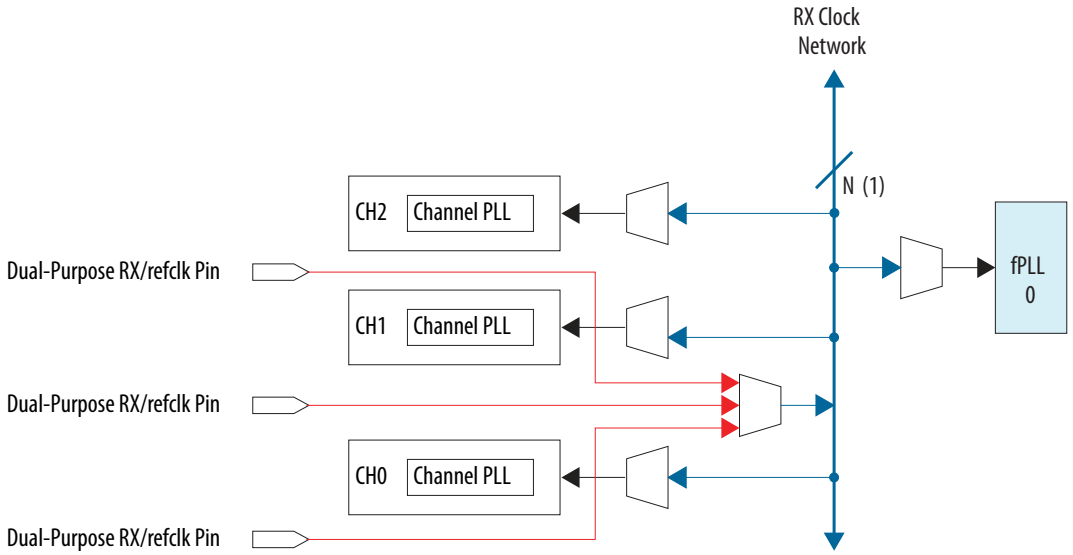
Dual-Purpose RX/refclk Pin

When not used as receiver, an RX differential pair can be used as an additional input reference clock source. The clock from the RX pins feed the RX clock network that spans all the channels on one side of the device.

Only one RX differential pair for every three channels can be used as input reference clock at a time. The following figure shows the use of dual-purpose RX/refclk differential pin as input reference clock source and the RX clock network.

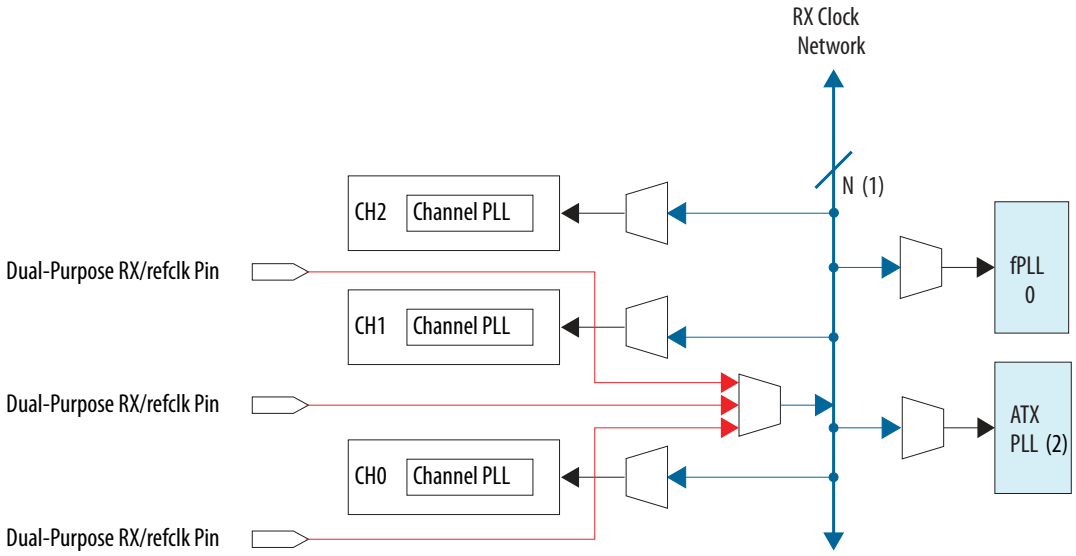
Note:
- An RX differential pair from another bank can be used as an input reference clock pin on the same side of the device.
- refclk switching cannot be performed when dual-purpose RX differential pins are used as refclk pins.

Figure 2-6: Dual-Purpose RX/refclk Pin as an Input Reference Clock



Note (1): N is the number of transceiver channels on a side divided by 3.

Figure 2-7: Dual-Purpose RX/refclk Pin as an Input Reference Clock for GZ Devices



Note (1): N is the number of transceiver channels on a side divided by 3.
Note (2): ATX PLL is available only for Arria V GZ devices.

Fractional PLL (fPLL)

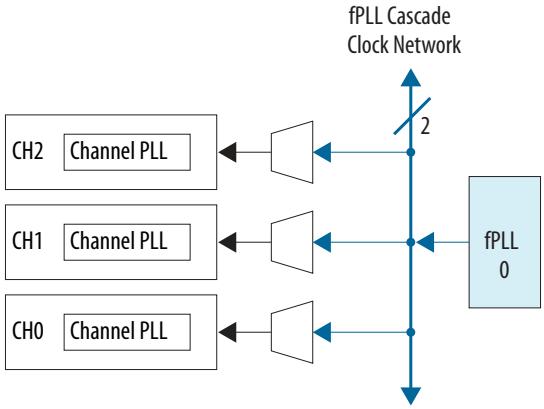
The fPLL clock output can be used as input reference clock source to transmitter PLL or CDR.

Cascading the fPLL to transmitter PLL or CDR enables you to use an input reference clock that is not supported by the transmitter PLL or CDR. The fPLL synthesizes a supported input reference clock for the transmitter PLL or CDR.

A fPLL is available for each group of three transceiver channels. Each fPLL drives one of two fPLL cascade clock network lines that can provide an input reference clock to any transmitter PLL or CDR on the same side of a device.

Note: An fPLL can also be used as a transmit PLL.

Figure 2-8: fPLL Clock Output as Input Reference Clock



Note: It is not recommended to use fractional PLL in fractional mode for transceiver applications as a TX PLL or for PLL cascading.

Internal Clocking

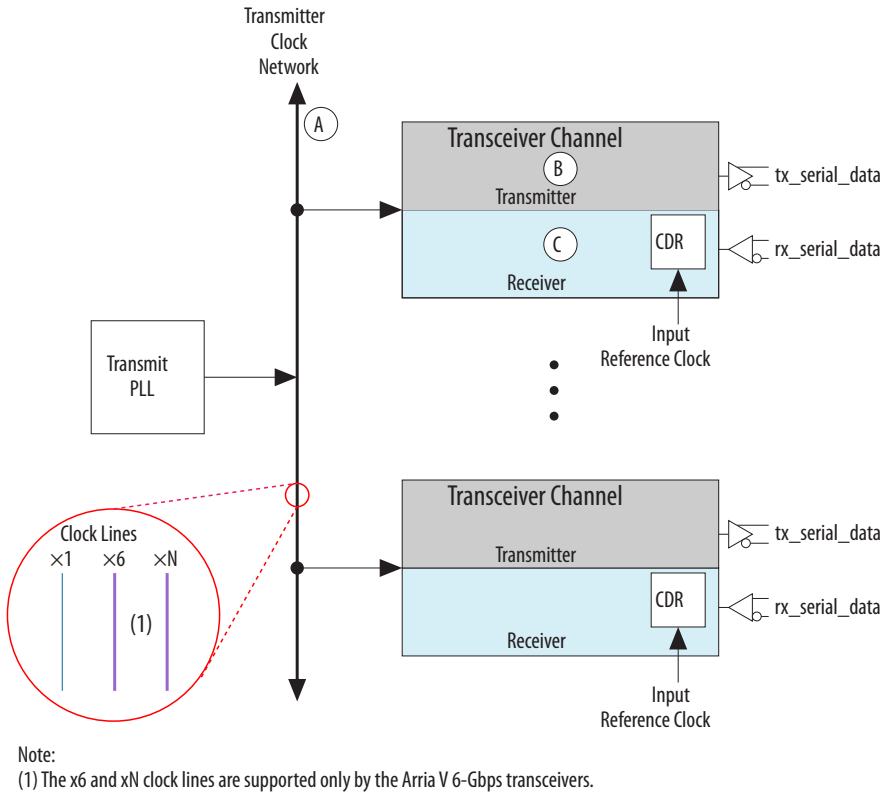
In the internal clocking architecture, different physical coding sublayer (PCS) configurations and channel bonding options result in various transceiver clock paths.

Table 2-3: Internal Clocking Subsections

The labels listed in the following table and shown in the figure following mark the three sections of the transceiver internal clocking.

Label	Scope	Description
A	Transmitter Clock Network	Clock distribution from transmitter PLLs to channels
B	Transmitter Clocking	Clocking architecture within transmitter channel datapath
C	Receiver Clocking	Clocking architecture within receiver channel datapath

Figure 2-9: Internal Clocking



Note: For Arria V GZ devices, the x6 clock lines can support data rates up to 12.5 Gbps and the xN clock lines can support data rates up to 9.8304 Gbps.

Transmitter Clock Network

The transmitter PLL is comprised of the ATX PLL (for GZ devices only) , CMU PLL, and fPLL.

All CMU PLLs are identical in architecture, but vary in the following:

- Usage capability: CMU PLL in channel 1 and 4 are capable of distributing a clock with accessibility to the transmitter clock network, while the rest only are able to clock the transmitter in the same channel only.
- Performance: Up to 6.5536 Gbps in GX and SX, except for the CMU PLL of channel 1 and 4 in GT and ST devices, which are capable of up to 10.3125 Gbps. In GZ devices, the CMU PLL in channel 1 and channel 4 can drive any transceiver channel up to 12.5 Gbps.

Table 2-4: Usage Capability of Each ATX PLL (for GZ devices) and CMU PLL Within a Transceiver Bank

CMU PLL Location in a Transceiver Bank	Clock Network Access	Maximum ATX / CMU PLL Performance (Gbps)	Maximum CMU PLL Performance (Gbps)		Usage Capability
		GZ Devices only	GX and SX Devices	GT and ST Devices	
CH 0	No	12.5	6.5536	6.5536	Clock transmitter within same channel only
CH 1	Yes	12.5	6.5536	10.3125	Clock transmitter within same channel only and other channels via clock network
CH 2	No	12.5	6.5536	6.5536	Clock transmitter within same channel only
CH 3	No	12.5	6.5536	6.5536	Clock transmitter within same channel only
CH 4	Yes	12.5	6.5536	10.3125	Clock transmitter within same channel only and other channels via clock network
CH 5	No	12.5	6.5536	6.5536	Clock transmitter within same channel only

The fPLLs adjacent to the transceiver banks provide an additional transmitter PLL source for clocking transceivers up to 3.125 Gbps. Two fPLLs are available as the transmitter PLL for every transceiver bank of six channels, or one fPLL for a bank of three channels.

The transmitter clock network routes the clock from the transmitter PLL to the transmitter channel. As shown in **Figure 2-9** , the transmitter clock network routes the clock from the transmit PLL to the transmitter channel. A clock divider provides two clocks to the transmitter channel:

- Serial clock—high-speed clock for the serializer
- Parallel clock—low-speed clock for the serializer and the PCS

Arria V transceivers support non-bonded and bonded transceiver clocking configurations:

- Non-bonded configuration—Only the serial clock from the transmit PLL is routed to the transmitter channel. The clock divider of each channel generates the local parallel clock. The x1 and xN (for Native PHY IP only) clock lines are used for non-bonded configurations. This configuration is available for both the 6-Gbps, 10-Gbps and 12.5 Gbps (GZ devices only) transceivers.
- Bonded configuration—Both the serial clock and parallel clock are routed from the central clock divider in channel 1 or 4 to the bonded transmitter channels. The x6 and xN clock lines are used for bonded configurations. This configuration is only available for 6 Gbps transceivers. Arria V GZ devices can support data rates upto 12.5 Gbps on the x6 clock lines and 8 Gbps using PCIe or 9.8304 Gbps using Native PHY IP on the xN clock lines.

The transmitter clock network is comprised of x1 (x1 and x1_fPLL), x6 and xN clock lines.

Table 2-5: Characteristics of x1, x6, and xN Clock Lines

Characteristics	x1	x1_fPLL	x6	x6_fPLL	xN
Clock Source	CMU PLL from CH 1 or CH 4 in a bank (serial clock only)	fPLL adjacent to transceivers (serial clock only)	Central clock divider from Ch 1 or Ch 4 in a bank (serial and parallel clock)	fPLL through the `x1_fPLL` line. The central clock divider resource of Ch 1 or Ch 4 in a bank is used (serial and parallel clock). However, the Ch 1 or Ch 4 can still be used as the receiver CDR.	x6 clock lines (serial and parallel clock)
Max Data Rate (Gbps)	10.3125 (GT and ST) 6.5536 (GX and SX)	3.125	6.5536	3.125	3.25 (18)
Clock Line Span	Within a transceiver bank	Within a group of 3 channels (0, 1, 2 or 3, 4, 5)	Within a transceiver bank	Within a transceiver bank	Across all channels in the same side of device
Non-bonded Configuration	Yes	Yes	Yes	No	Yes
Bonded Configu-ration	No	No	Yes	Yes	Yes

(18) Only for PCIe Gen2 configurations, xN clock lines can support a maximum data rate of 5 Gbps. There is no xN data rate limit check in the Quartus II software. The limit in the handbook is the golden reference.

Table 2-6: Data Rates and Spans Supported by Clock Sources and Clock Networks in Arria V GZ Devices

Clock Network	Transceiver Channel	Clock Source	Max Data Rate	Bonding	Span
x1	GX	ATX PLLs in a transceiver bank	12.5 Gbps (19)	No	Transceiver bank
		CMU PLLs in a transceiver bank	12.5 Gbps (19)		Transceiver bank
		Fractional PLLs in a transceiver bank	3.125 Gbps		fPLLs can only span upper or lower 3 channels in a transceiver bank.
xN (Native PHY)	GX	ATX PLLs in a transceiver bank provide a serial clock to the central clock dividers of Ch1 and Ch4. The central clock dividers in the transceiver bank drive the x6 clock lines. The xN clock lines receive only the serial clock from the x6 clock lines.	8 Gbps	No	xN lines span a side of the device. Specified datarate can drive up to 13 data channels above and up to 13 data channels below TX PLL.
		Channel PLLs in a transceiver bank provide a serial clock to the central clock dividers of Ch1 and Ch4. The central clock dividers in the transceiver bank drive the x6 clock lines. The xN clock lines receive only the serial clock from the x6 clock lines.	7.99 Gbps		
		Fractional PLLs in a transceiver bank provide a serial clock to the central clock dividers of Ch1 and Ch4. The central clock dividers in the transceiver bank drive the x6 clock lines. The xN clock lines receive only the serial clock from the x6 clock lines.	3.125 Gbps		
x6	GX	ATX PLLs in a transceiver bank provide a serial clock to the central clock dividers of Ch1 and Ch4. The central clock dividers in the	12.5 Gbps (19)	Yes	Transceiver bank

(19) For the fastest speed grade only. For the remaining speed grades, refer to the *Arria V Device Datasheet* .

Clock Network	Transceiver Channel	Clock Source	Max Data Rate	Bonding	Span
		transceiver bank drive the x6 clock lines. The x6 clock lines receive both the serial and parallel clock from the central clock dividers.			
		The channel (CMU) PLLs provide a serial clock to the central clock dividers of Ch1 and Ch4. The central clock dividers in the transceiver bank drive the x6 clock lines. The x6 clock lines receive both the serial and parallel clock from the central clock dividers.	12.5 Gbps (19)		
		Fractional PLLs provide a serial clock to the central clock dividers of Ch1 and Ch4. The central clock dividers in the transceiver bank drive the x6 clock lines. The x6 clock lines receive both the serial and parallel clock from the central clock dividers.	3.125 Gbps		
x6 PLL Feedback Compensation (20)	GX	One ATX PLL per bonded transceiver bank provides a serial clock to the central clock dividers of Ch 1 and Ch 4. The central clock dividers in the transceiver bank drive the x6 clock lines and provide feedback path to the ATX PLL. The x6 clock lines receive both the serial and parallel clocks from the central clock dividers.	12.5 Gbps (19)	Yes	x6 lines span a transceiver bank. The x6 lines across multiple transceiver banks can be bonded together through PLL feedback compensation path to span the entire side of the device.

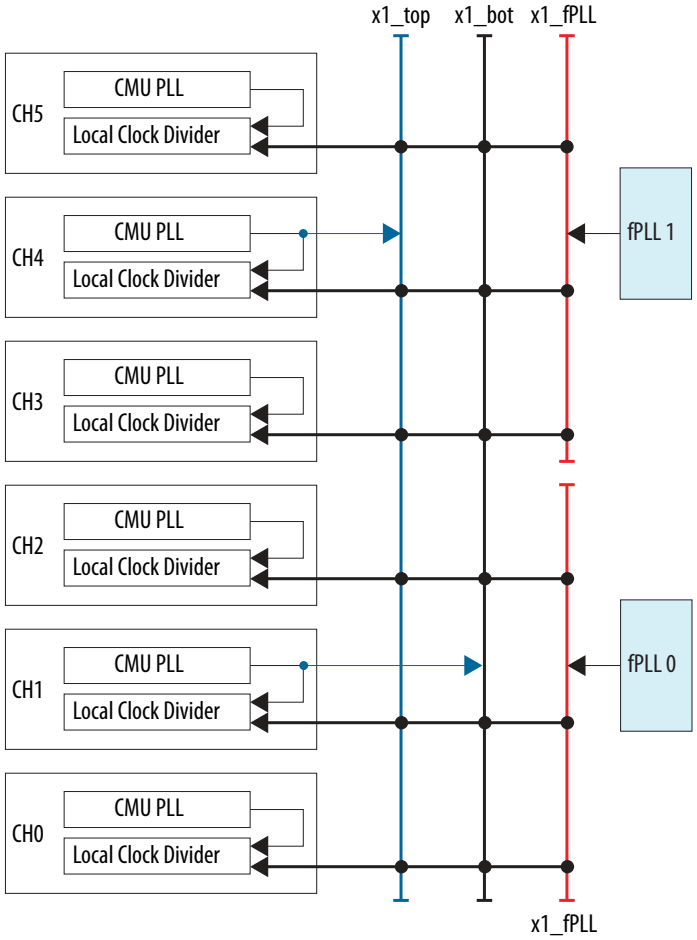
(20) The input reference clock frequency of the transmit PLL must be the same as the parallel clock frequency which clock the PCS bonded channels.

Clock Network	Transceiver Channel	Clock Source	Max Data Rate	Bonding	Span
		One CMU PLL per bonded transceiver bank provides a serial clock to the central clock dividers of Ch 1 and Ch 4. The central clock dividers in the transceiver bank drive the x6 clock lines and provide feedback path to the CMU PLL. The x6 clock lines receive both the serial and parallel clocks from the central clock dividers.	12.5 Gbps (19)		
xN (PCIe) (21)	GX	The ATX or channel (CMU) PLL provides a serial clock to the central clock dividers of Ch1 and Ch4. The central clock dividers in the transceiver bank drive the x6 clock lines. The xN clock lines receive the serial and parallel clocks from the x6 clock lines.	8 Gbps	Yes	xN lines span a side of the device, but can bond only up to eight contiguous data channels.

(21) For more information about PCIe x8 configurations, refer to the *Transceiver Configurations in Arria V GZ Devices* chapter.

Clock Network	Transceiver Channel	Clock Source	Max Data Rate	Bonding	Span
xN (Native PHY)	GX	ATX PLLs in a transceiver bank provide a serial clock to the central clock dividers of Ch1 and Ch4. The central clock dividers in the transceiver bank drive the x6 clock lines. The xN clock lines receive the serial and parallel clocks from the x6 clock lines.	9.8304 Gbps	Yes	xN lines span a side of the device. Specified datarate can bond up to 7 contiguous data channels above and up to 7 contiguous data channels below TX PLL.
			8 Gbps	Yes	xN lines span a side of the device. Specified datarate can bond up to 13 contiguous data channels above and up to 13 contiguous data channels below TX PL
		Channel (CMU) PLLs in a transceiver bank provide a serial clock to the central clock dividers of Ch1 and Ch4. The central clock dividers in the transceiver bank drive the x6 clock lines. The xN clock lines receive the serial and parallel clocks from the x6 clock lines.	7.99 Gbps	Yes	xN lines span a side of the device. Specified datarate can bond up to 13 contiguous data channels above and up to 13 contiguous data channels below TX PL
		Fractional PLLs (fPLLs) in a transceiver bank provide a serial clock to the central clock dividers of Ch1 and Ch4. The central clock dividers in the transceiver bank drive the x6 clock lines. The xN clock lines receive the serial and parallel clocks from the x6 clock lines.	3.125 Gbps		

Figure 2-10: x1 Clock Line Architecture (up to 6.5536 Gbps)

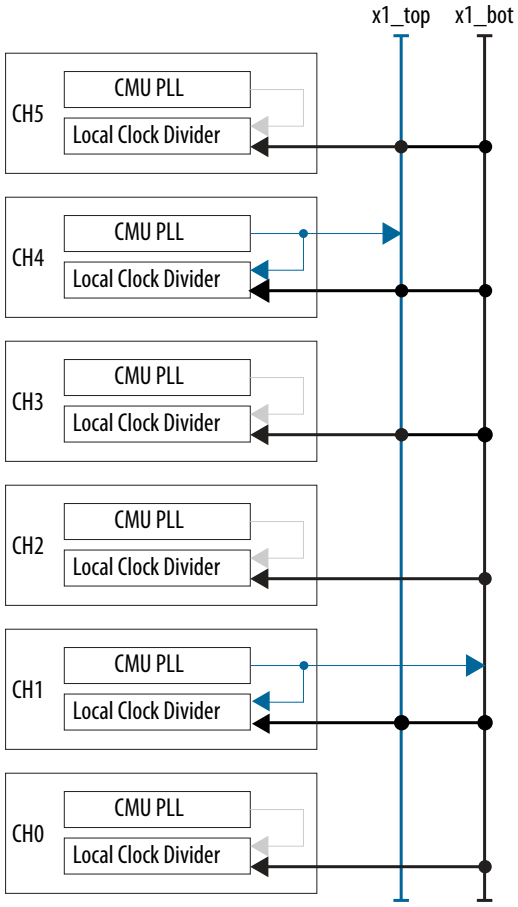


Note: All clock lines shown in this figure carry the serial clock only. x1_fPLL can support data rates upto 3.125 Gbps only.

The x1 clock lines are driven by serial clocks of CMU PLLs from channels 1 and 4. The serial clock in the x1 clock line is then distributed to the local and central clock dividers of every channel within a transceiver bank.

The x1_fPLL clock lines are driven by the serial clocks of the adjacent fPLL. The serial clock in the x1_fPLL clock lines, is then distributed to the local and central clock dividers of channels within a group of three channels (0, 1, 2 or 3, 4, 5).

Figure 2-11: x1 Clock Line Architecture (more than 6.5536 Gbps)

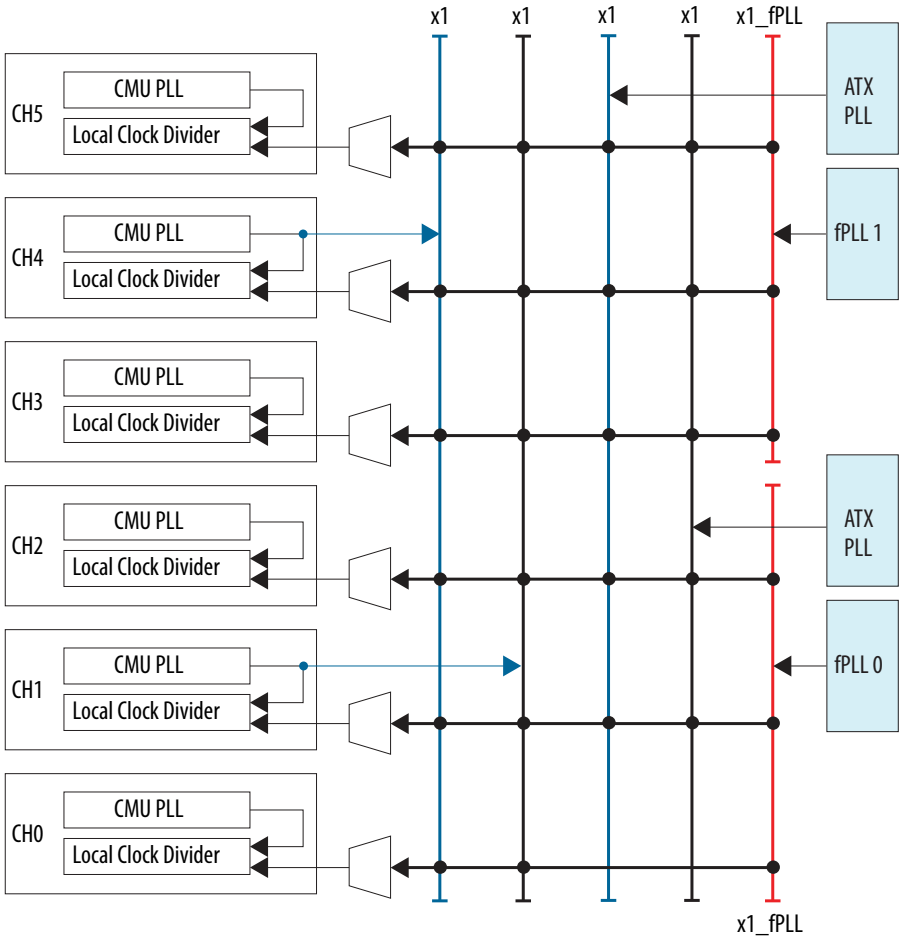


Note: All clock lines shown in this figure carry the serial clock only.

For serial data rates beyond 6.5536 Gbps (10-Gbps channels only in GT and ST devices). The x1 clock lines are driven by the serial clocks of CMU PLLs from channels 1 and 4. The serial clock in the x1 clock line is then distributed to the local and central clock dividers of every channel within a transceiver bank.

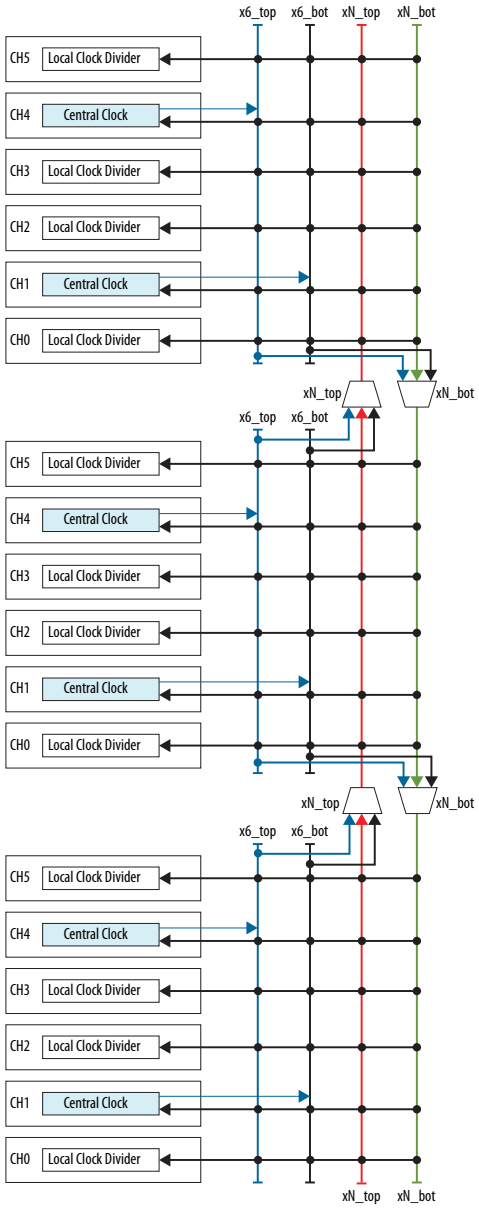
Note: When you configure the channel PLL as a CMU PLL to drive the local clock divider, or the central clock divider of its own channel, you cannot use the channel PLL as a CDR. Without a CDR, you can use the channel only as a transmitter channel.

Figure 2-12: x1 Clock Line Architecture (up to 12.5 Gbps) for GZ Devices



Note: All clock lines shown in this figure carry the serial clock only. In Arria V GZ devices, fPLLs support data rate up to 3.125 Gbps only.

Figure 2-13: x6 and xN Clock Line Architecture



Note: All the clock lines shown in this figure carry both the serial and parallel clocks.

The x6 clock lines are driven by serial and parallel clocks from the central clock divider in channels 1 and 4. For channels within a bank, the serial and parallel clocks in the x6 clock line is then distributed to every channel within a transceiver bank.

The xN clock lines extend the clocking reach of the x6 clock line to all channels within the same side of the device. To reach a xN clock line, the clocks must be provided on the x6 clock line. The serial and parallel clocks in the x6 clock line is distributed to every channel within a transceiver bank. The serial and parallel clocks are distributed to other channels beyond the bank using the xN clock line.

In bonded configurations, serial and parallel clocks from the x6 or xN clock lines are received by the clock divider of every bonded channel and fed directly to the serializer. In a non-bonded configuration, the

clock divider of every non-bonded channel receives the serial clock from the x6 or xN clock lines and generates the individual parallel clock to the serializer.

Note:
- In a bonded configuration, bonded channels must be placed contiguously without leaving a gap between the channels, except when the gap channel is a CMU PLL.
- xN bonded configuration is only supported by PIPE and Native PHY IP.

Transceiver Configurations in Arria V GZ Devices

Arria V Device Datasheet

Transmitter Clocking

Transmitter (TX) clocking refers to the clocking architecture that is internal to the TX channel of a transceiver.

The following figure shows how the clock divider provides the serial clock to the serializer, and the parallel clock to the serializer and TX PCS. When the byte serializer is not used, the parallel clock is used to clock all the blocks up to the read side of the TX phase compensation FIFO. For configurations with the byte serializer, the parallel clock is divided by a factor of two for the byte serializer and the read side of the TX phase compensation FIFO. The read side clock of the TX phase compensation FIFO is also forwarded to the FPGA fabric to interface the FPGA fabric with the transceiver.

Figure 2-14: Clocking Architecture for Transmitter PCS and PMA Configuration

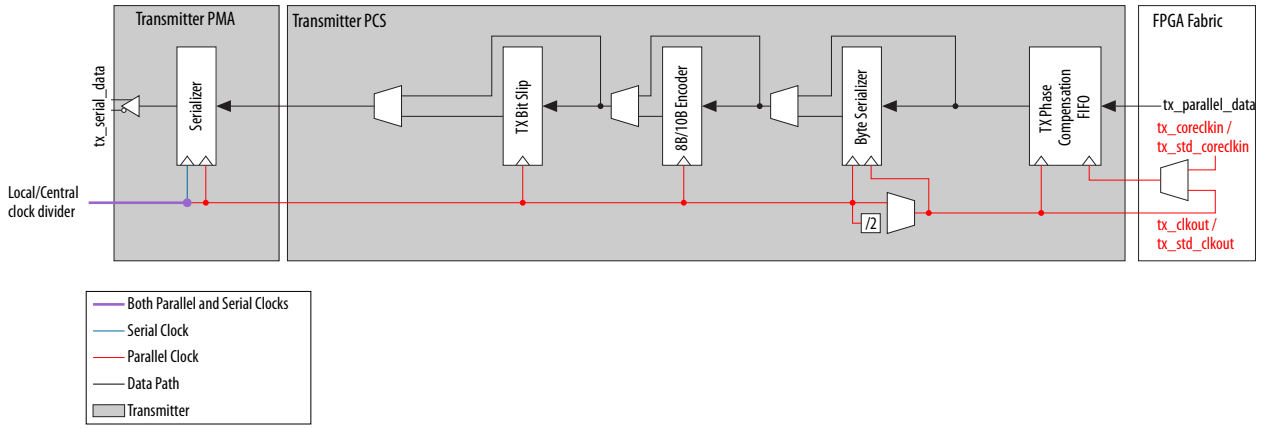

Table 2-7: Clock Sources for All TX PCS Blocks

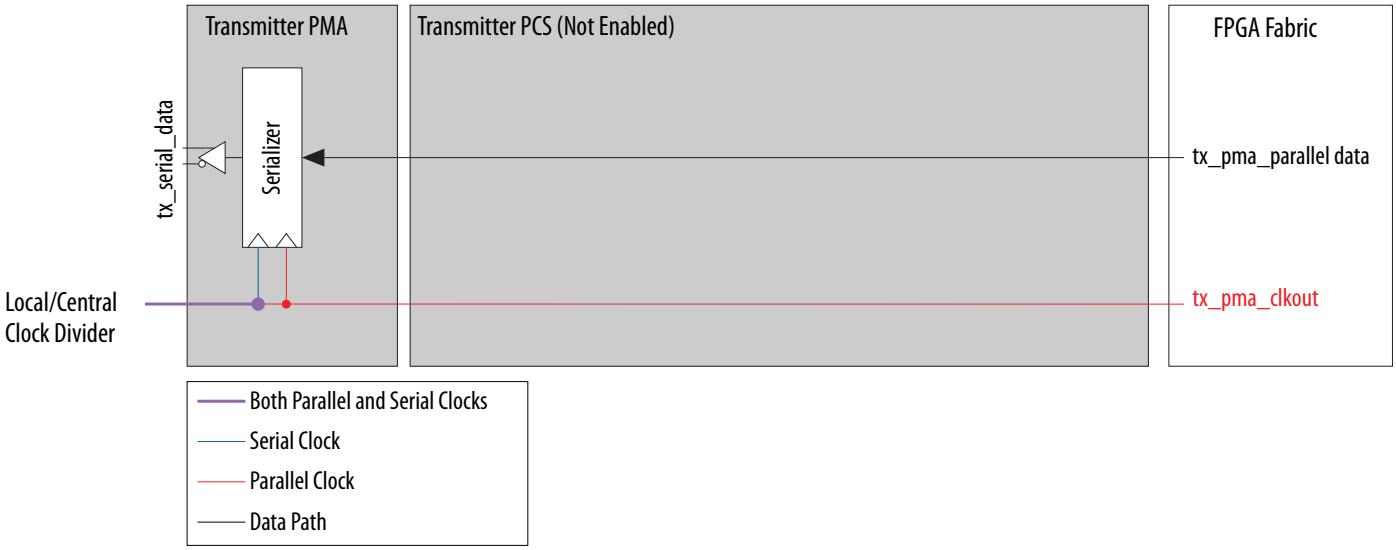
PCS Block	Side	Clock Source
TX Phase Compensation FIFO	Write	FPGA fabric write clock, driven either by tx_clkout or tx_coreclkin
	Read	Parallel clock (divided). Clock forwarded to FPGA fabric as tx_clkout
Byte Serializer	Write	Parallel clock (divided) either by factor of 1 (not enabled), or factor of 2 (enabled)
	Read	Parallel clock
8B/10B Encoder	—	Parallel clock

PCS Block	Side	Clock Source
TX Bit Slip	—	Parallel clock

The following figure shows how the clock divider provides the serial and parallel clock to the serializer in a transmitter PMA configuration. The parallel clock is forwarded to the FPGA fabric to interface the FPGA fabric with the TX PMA directly, bypassing the PCS blocks.

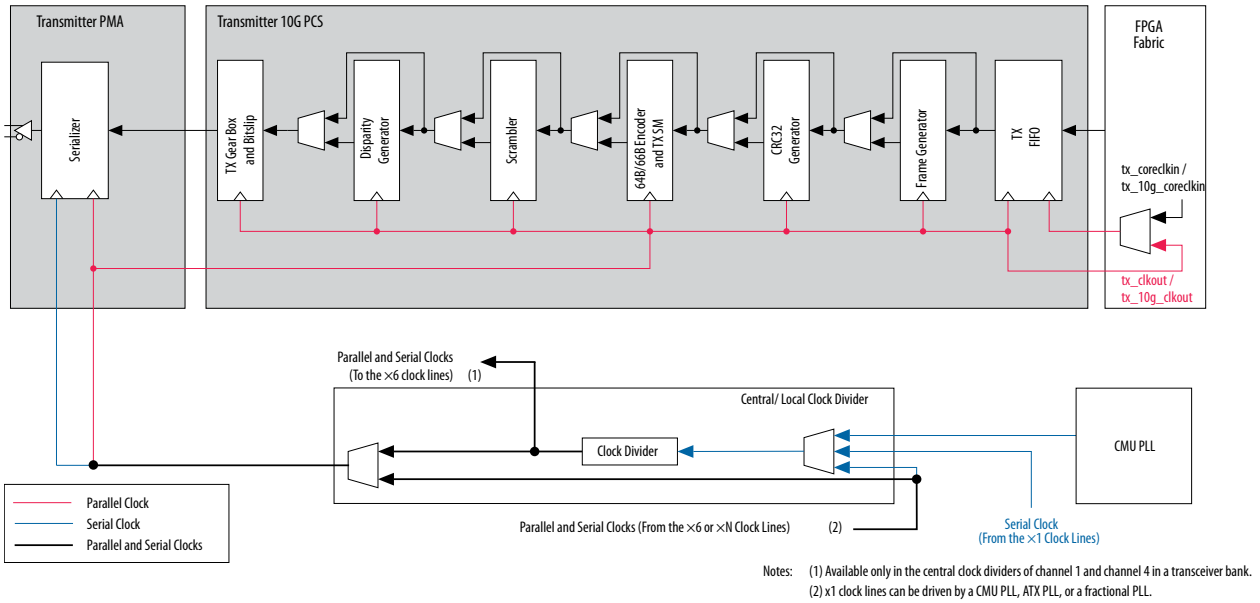
Figure 2-15: Clocking Architecture for Transmitter PMA Only Configuration



Transmitter 10G PCS Clocking for GZ Devices

The following figure shows the clocking scheme for the transmitter 10G PCS and transmitter physical medium attachment (PMA). The clock divider block provides the serial clock to the serializer of the transmitter PMA and the parallel clock to the transmitter PCS. In the 10G PCS channel, the parallel clock is used by all the blocks up to the read side of the transmitter (TX) FIFO.

Figure 2-16: Transmitter 10G PCS Clocking for GZ Devices



Non-Bonded Channel Configurations

The channel clock path for non-bonded configurations can be driven by the x1, or the x6 and xN clock lines.

Table 2-8: Clock Path for Non-Bonded Configurations

The following table describes the clock path for non-bonded configuration with the ATX PLL, CMU PLL, and fPLL as TX PLL using various clock lines.

Clock Line	Transmitter PLL	Clock Path
x1	ATX PLL(22)	ATX PLL » x1 » individual clock divider » serializer
	CMU	CMU PLL » x1 » individual clock divider » serializer
	fPLL	fPLL » x1_fPLL » individual clock divider » serializer
x6, xN	ATX PLL(22)	ATX PLL » central clock divider » x6 » xN » individual clock divider » serializer
	CMU	CMU PLL » central clock divider » x6 » xN » individual clock divider » serializer (23)
	fPLL	fPLL » x1_fPLL » central clock divider » x6 » individual clock divider » serializer (23)

(22) ATX PLL is available only for GZ devices.
(23) Non-bonded channels within same bank as TX PLL are driven by clocks from x6 clock line, and channels in other banks are driven from xN clock line.

Figure 2-17: Three Non-Bonded Transmitter Channels Driven by CMU PLL using x1 Clock Line Within a Transceiver Bank

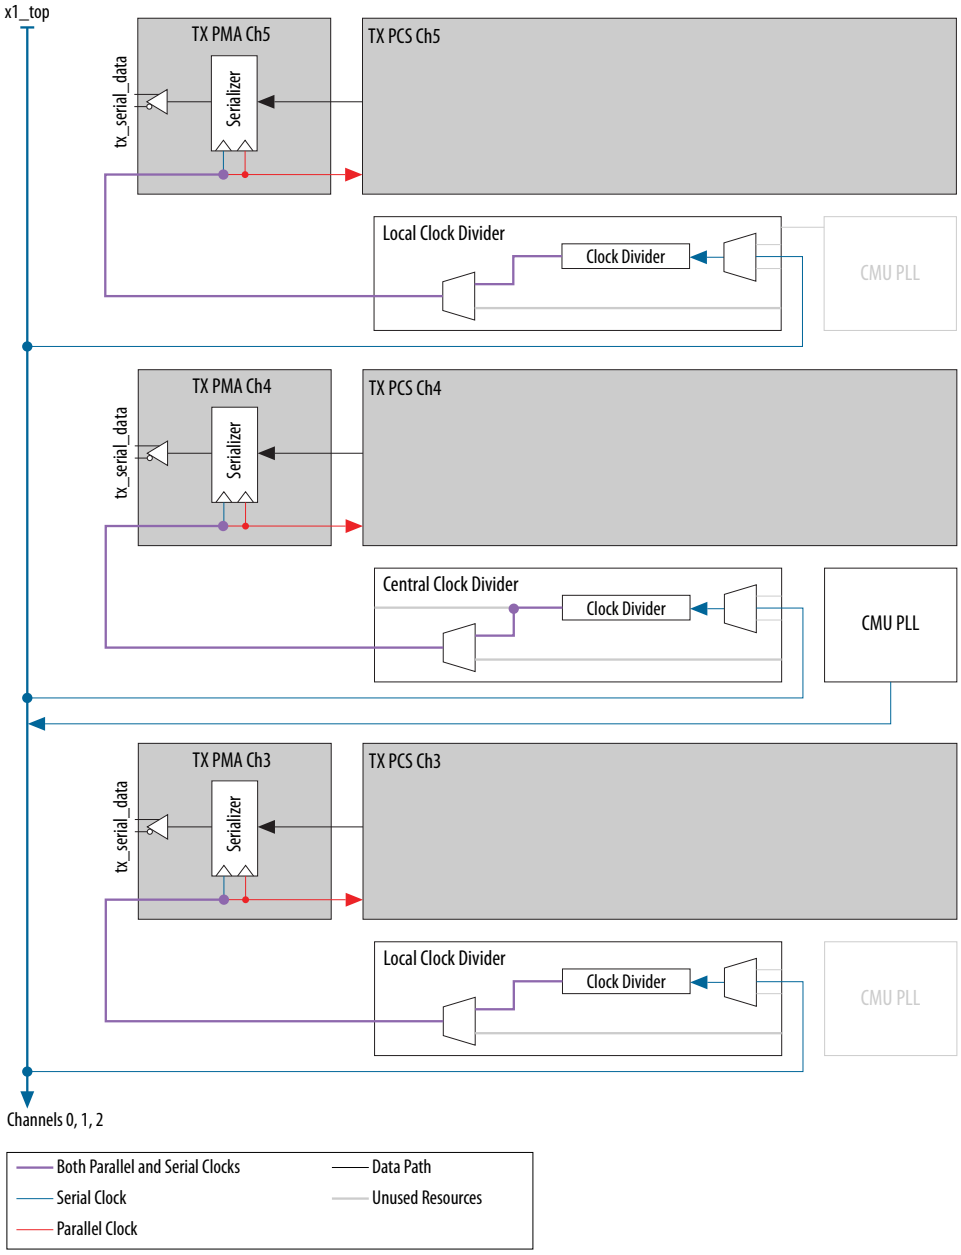


Figure 2-18: Three Non-Bonded Transmitter Channels Driven by fPLL using x1 Clock Line Within a Transceiver Bank

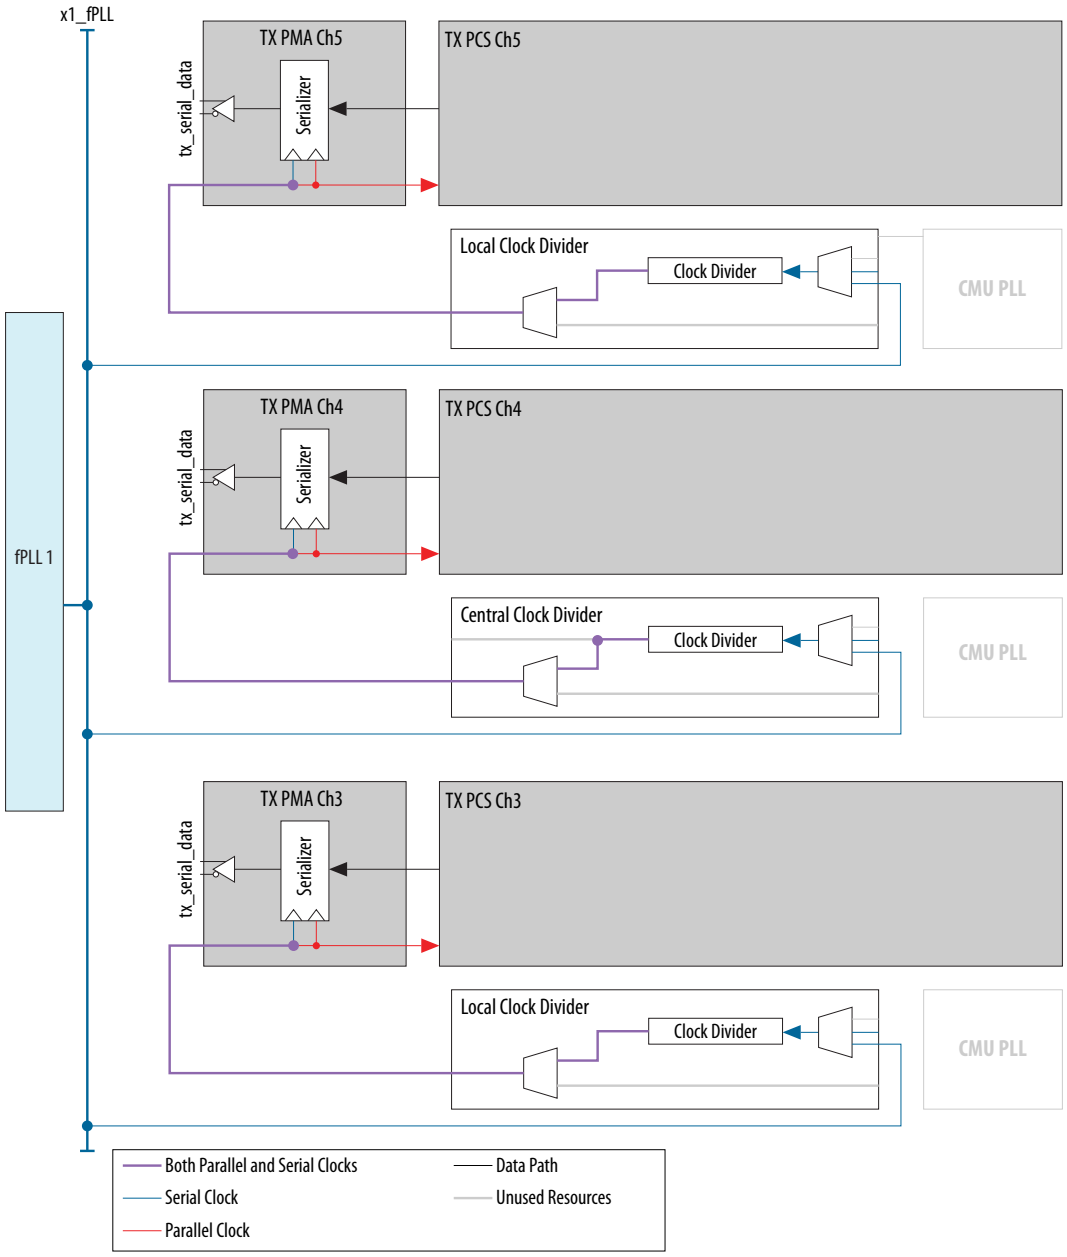

Figure 2-19: Three Non-Bonded Transmitter Channels Driven by ATX PLL using x1 Clock Line Within a Transceiver Bank for GZ Devices.

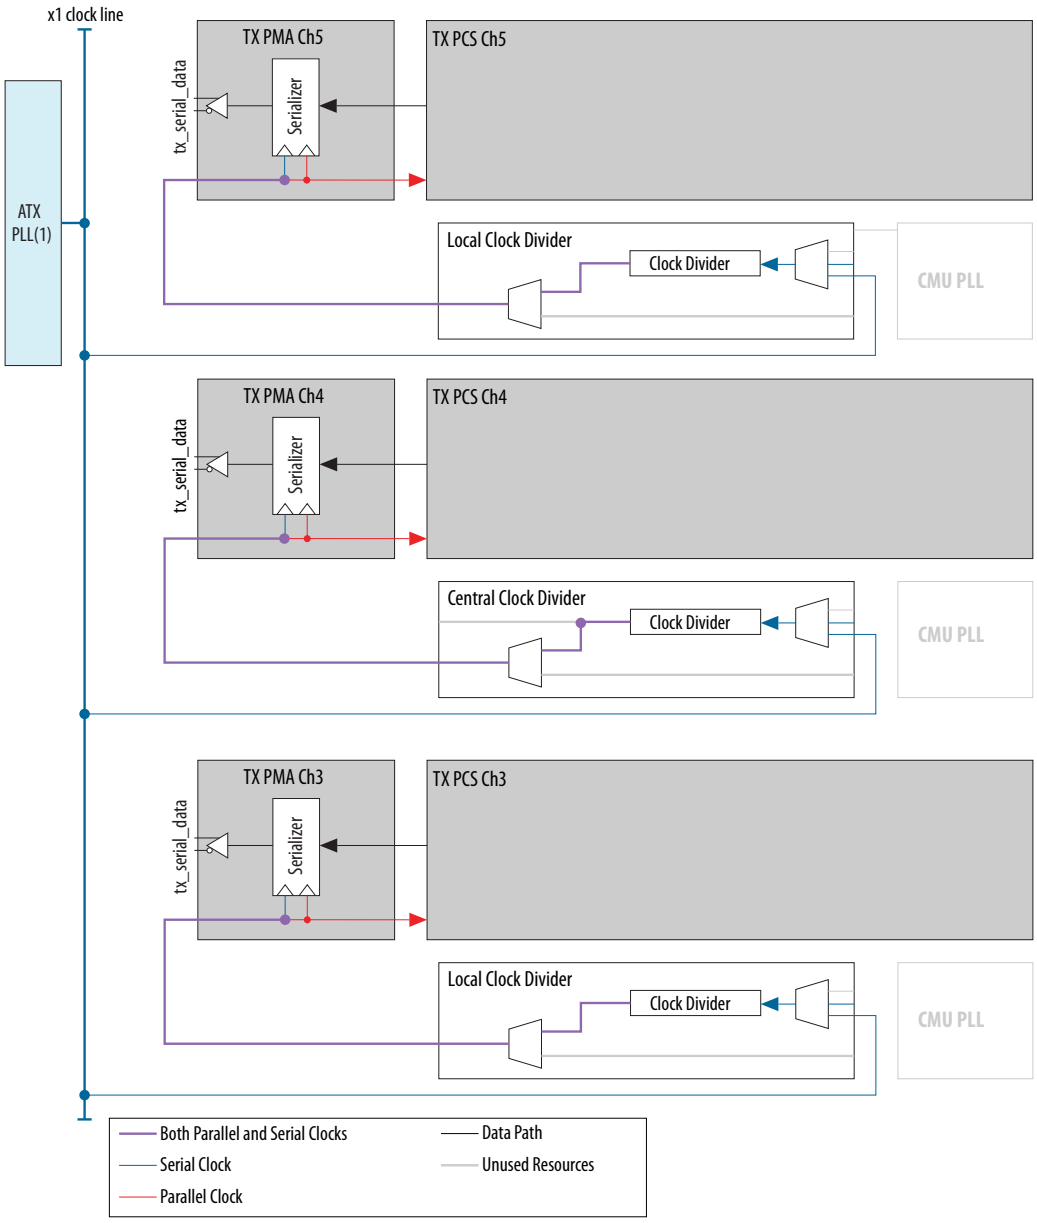

Note : (1) ATX PLL is available only for Arria V GZ devices.

Figure 2-20: Three Non-Bonded Transmitter Channels Driven by CMU PLL using x6 and xN Clock Lines Across Multiple Transceiver Banks

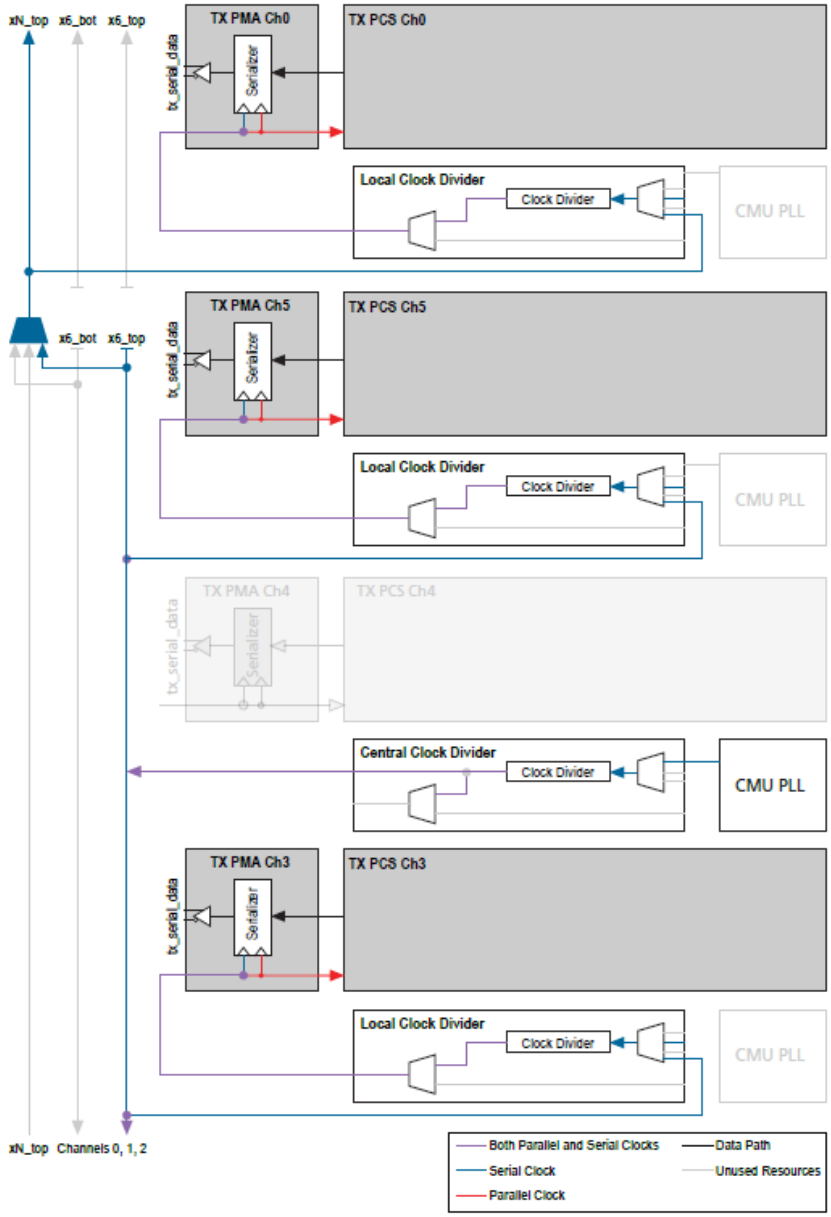

Figure 2-21: Three Non-Bonded Transmitter Channels Driven by fPLL using x6 and xN Clock Line Across Multiple Transceiver Banks

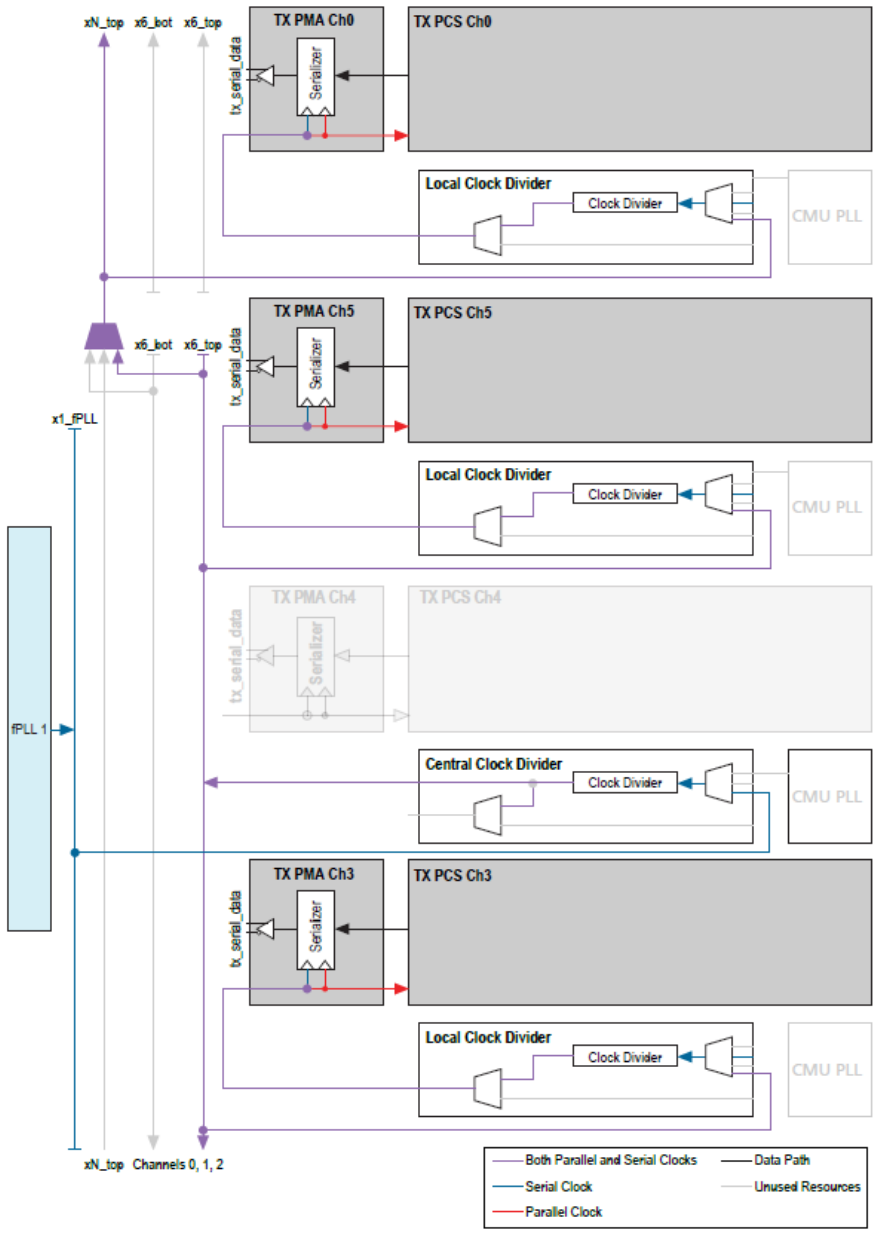


When the fPLL is used to drive more than three non-bonded channels, the channel where the central clock divider resides adjacent to the fPLL cannot be used as a transmitter. The fPLL uses a central clock divider to access the x6 clock network when driving more than three non-bonded channels, so the divider is no longer available to implement a transmitter. For xN non-bonded configurations, the ch 1 or ch 4 transceiver bank where the central clock divider resides cannot be used as a data channel since the parallel clock cannot be generated in this channel.

Bonded Channel Configurations

The channel clock path for bonded configurations is driven by the x6 and xN clock lines.

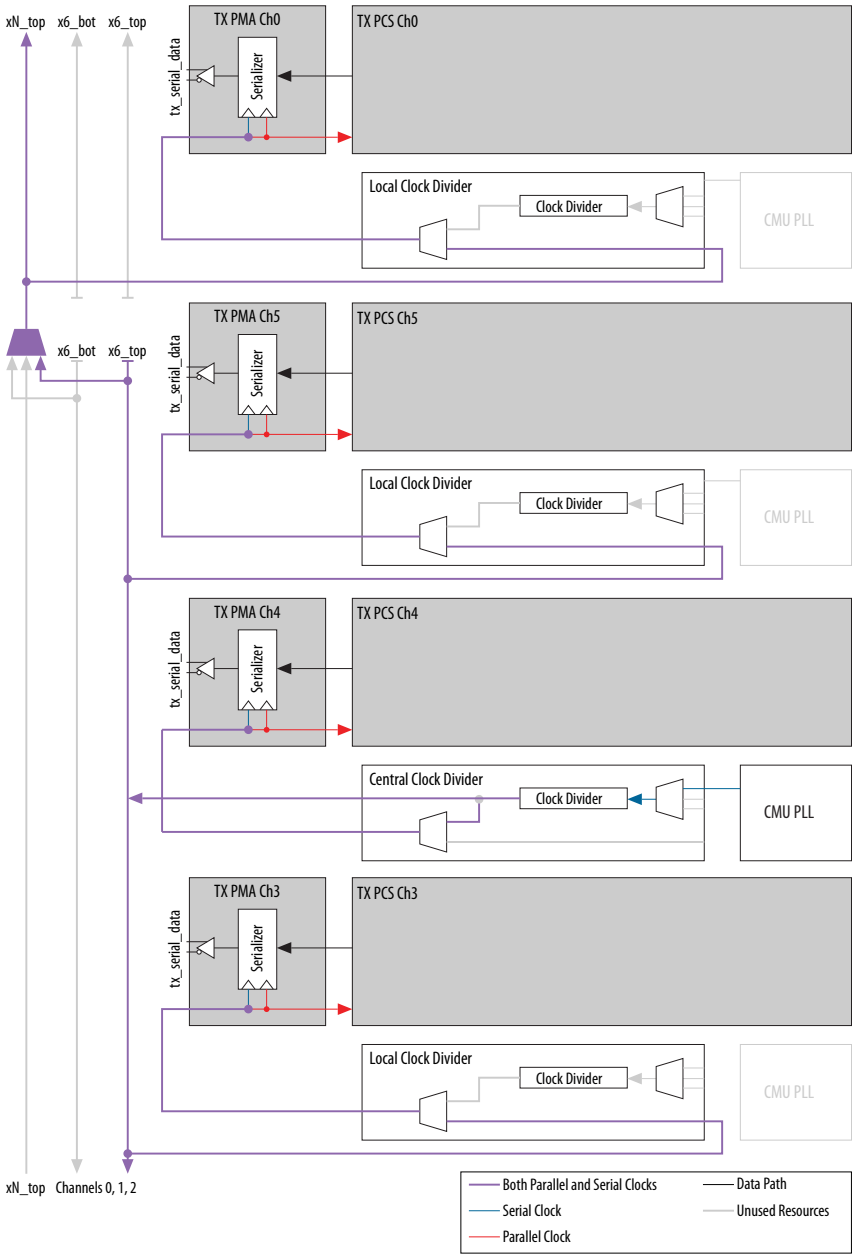
Table 2-9: Clock Path for Bonded Configurations

The following table describes the clock path for a bonded configuration with ATX PLL, CMU PLL, or fPLL as TX PLL using various clock lines.

Clock Line	Transmitter PLL	Clock Path
x6, xN	ATX PLL[25]	CMU PLL » central clock divider » x6 » xN » serializer
	CMU	CMU PLL » central clock divider » x6 » xN » serializer [24]
	fPLL	fPLL » x1_fPLL » central clock divider » x6 » serializer [24]
x6 PLL Feedback Compensation [26]	ATX PLL [25]	ATX PLL » central clock divider » x6 » serializer
	CMU	CMU PLL » central clock divider » x6 » serializer

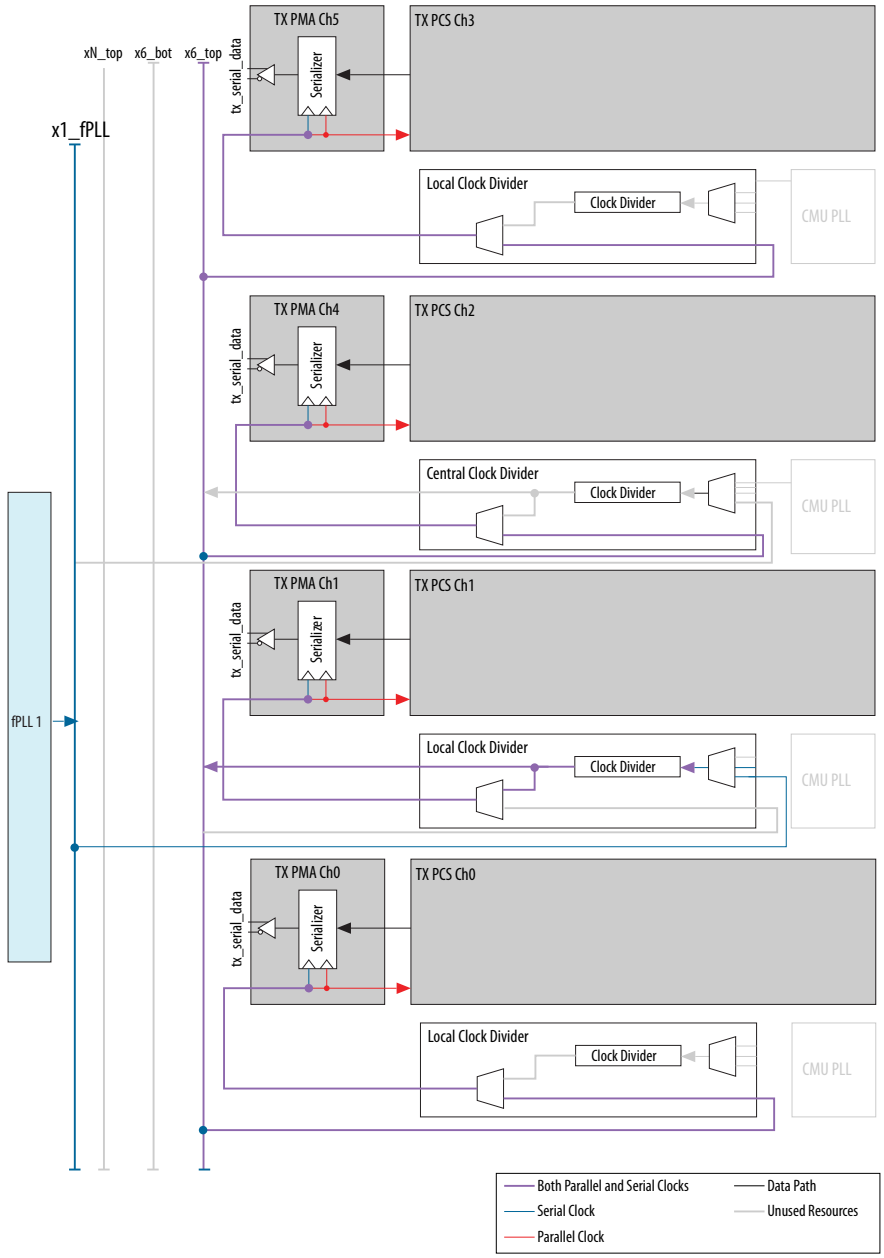
[24] Bonded channels within same bank as the TX PLL are driven by clocks from the x6 clock line, and channels in other banks are driven from the xN clock line.
[25] ATX PLL is available for GZ devices only.
[26] x6 PLL Feedback Compensation is available for GZ devices only.

Figure 2-22: Four Bonded Transmitter Channels Driven by CMU PLL using x6 and xN Clock Lines Across Multiple Transceiver Banks



Note: When channel PLL is configured as a CMU PLL to drive the local clock divider or the central clock divider of its own channel, the channel PLL cannot be used as a CDR. Without a CDR, the channel can be used only as a transmitter.

Figure 2-23: Four Bonded Transmitter Channels Driven by fPLL using x6 Clock Line Within a Transceiver Bank



Note:
- When using the fPLL to drive bonded channels, assign logical channel 0 to the channel where the central clock divider is used for fPLL clocks to access the x6 clock line. Using the preceding figure as an example, assign `tx_serial_data[0]` to the transmitter channel 4 pin location.
- For xN bonded configurations, the channel where the central clock divider resides (ch 1 or ch 4) can be used as a data channel as the parallel clock can be generated in this channel.

Bonded Channel Configurations Using the PLL Feedback Compensation Path for GZ Devices

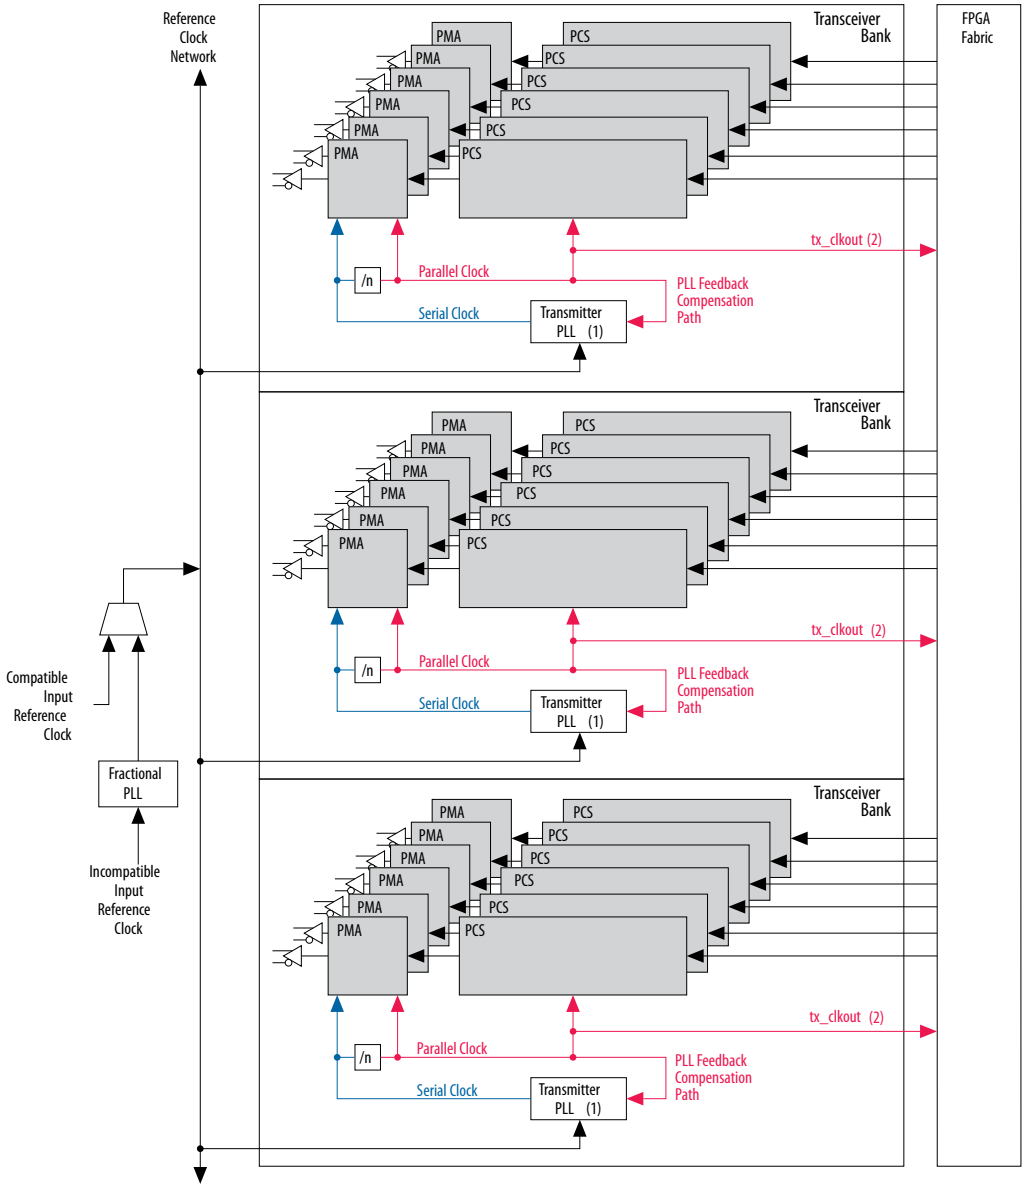
You can bond channels across multiple banks by using the PLL feedback compensation path.

The PLL feedback compensation path loops the parallel clock, which is used by the PCS blocks, back to the transmitter PLL. The PLL feedback compensation path synchronizes the parallel clock used to clock the PCS blocks in all transceiver banks with the `refclk`. You can use the PLL feedback compensation path to reduce channel-to-channel skew, which is introduced by the clock divider in each transceiver bank.

To bond channels using the PLL feedback compensation path, the input reference clock frequency used by the transmitter PLL must be the same as the parallel clock that clocks the PCS of the same channel.

Note: If the input reference clock frequency is not equal to the parallel clock frequency, use a fractional PLL to synthesize an input reference clock with the same frequency as the parallel clock.

Figure 2-24: Three Transceiver Bank Channels Bonded Using the PLL Feedback Compensation Path for GZ Devices



Notes: (1) The transmitter PLL can be an ATX PLL, or a CMU PLL. You can have up to six channels per bank with an ATX PLL and four channels per bank with a CMU PLL.
(2) tx_clkout from any of the banks can be used with the FPGA fabric-transceiver interface for all the bonded channels.

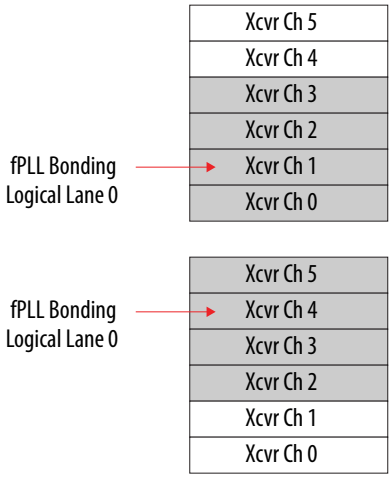
Note:
- Every transceiver bank with a bonded channel configured using the PLL feedback compensation path consumes a transmit PLL.
- fPLL does not support PLL feedback compensation when used as a TX PLL.

Transceiver Channel Placement Guidelines for fPLL in Transmit PLL Bonded Configuration (Except GZ Devices)

The fPLL as transmit PLL, when configured in bonded configuration, has placement restrictions. All channels need to be placed within one transceiver bank. For the example shown in the following figure, all four channels must be placed within one transceiver bank. A link cannot span across two banks. The channel placement must also be contiguous.

Figure 2-25: Transceiver Channel Placement for fPLL in a Transmit PLL Bonded Configuration

The following figure shows the allowed channel placement when using a x4 bonded configuration. The logical lane 0 must be placed in either Ch1 or Ch4.

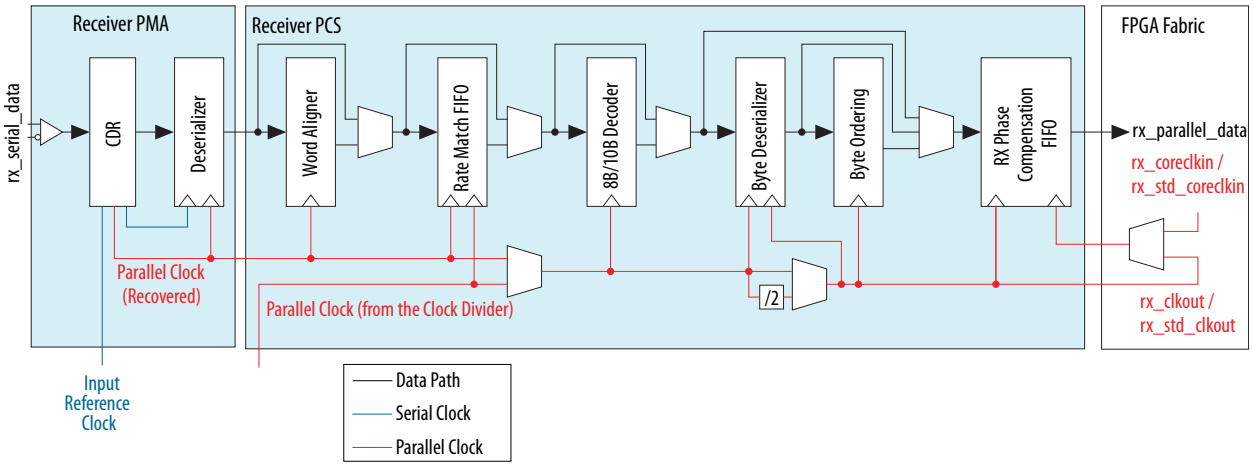


Note: A QSF assignment statement can be used to change the Logical Lane 0 assignment to a different transceiver channel.

Receiver Clocking

Receiver clocking refers to the clocking architecture internal to the receiver channel of a transceiver.

Figure 2-26: Clocking Architecture for Receiver PCS and PMA Configuration



The CDR in the PMA of each channel recovers the serial clock from the incoming data and generates the parallel clock (recovered) by dividing the serial clock (recovered). The deserializer uses both clocks. The receiver PCS can use the following clocks depending on the configuration of the receiver channel:

- Parallel clock (recovered) from the CDR in the PMA
- Parallel clock from the clock divider that is used by the channel's transmitter PCS

(27) Available for Arria V GZ devices only.

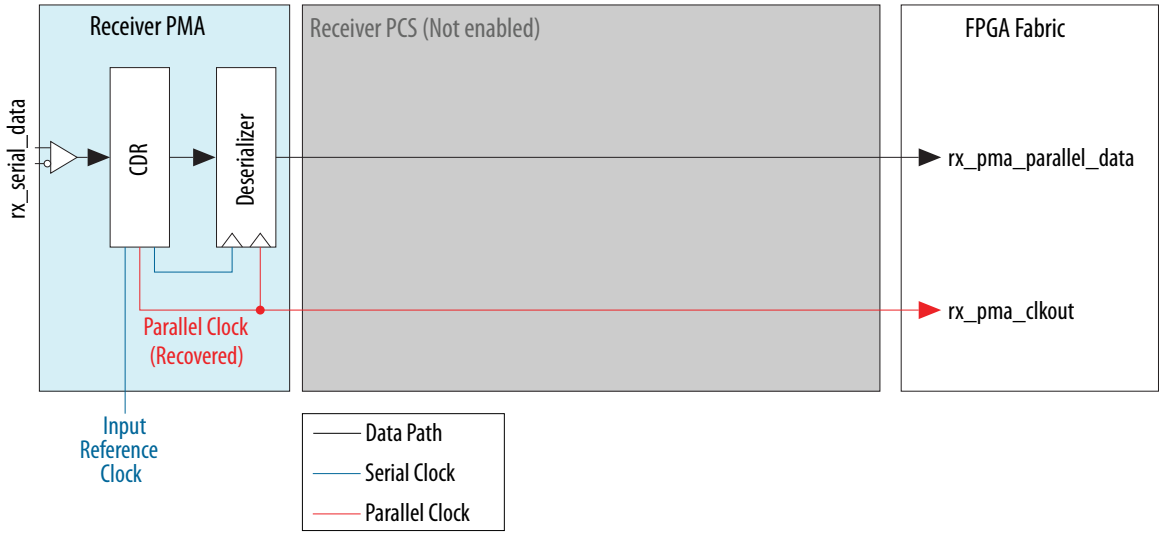
(28) For more information about loopback mode, refer to the *Transceiver Loopback Support* chapter in Arria V Devices.

Table 2-10: Clock Sources for All Receiver PCS Blocks

PCS	Block	Side	Clock Source
Standard	Word aligner	-	Parallel clock (recovered)
	Rate match FIFO	Write	Parallel clock (recovered)
		Read	Parallel clock from the clock divider
	8B/10B decoder	-	• Rate match FIFO is not used-Parallel clock (recovered) • Rate match FIFO is used-Parallel clock from the clock divider
	Byte deserializer	Write	• Rate match FIFO is not used-Parallel clock (recovered) • Rate match FIFO is used-Parallel clock from the clock divider
		Read	Divided down version of the write side clock depending on the deserialization factor of 1 or 2, also called the parallel clock (divided)
	Byte ordering	-	Parallel clock (divided)
	Receiver (RX) phase compensation FIFO	Write	Parallel clock (divided). This clock is also forwarded to the FPGA fabric.
		Read	Clock sourced from the FPGA fabric
10G[27]	All other PCS blocks		• Regular mode: parallel clock (recovered) • Loopback mode: parallel clock from the clock divider.[28]

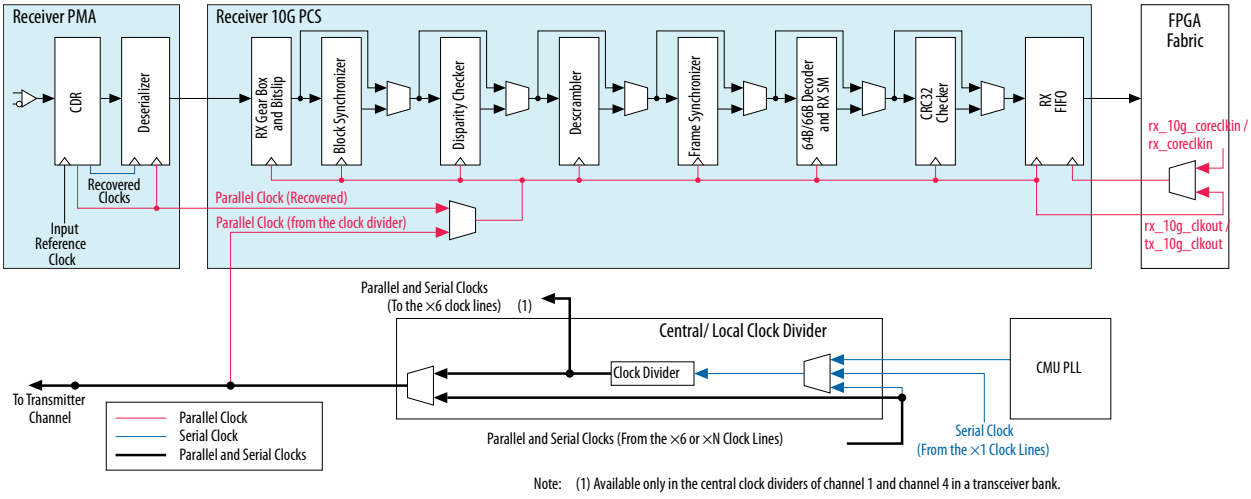
Figure 2-27: Clocking Architecture for Receiver PMA Only Configuration

The parallel recovered clock from the CDR and deserializer is forwarded to the FPGA fabric to interface FPGA fabric with the receiver PMA directly, bypassing the PCS blocks.



Clocking Architecture for Receiver 10G PCS and the Receiver PMA for GZ Devices.

Figure 2-28: Clocking Architecture for 10G PCS and the Receiver PMA for GZ Devices



Related Information

- Transceiver Loopback Support in Arria V Devices

Receiver Non-Bonded Channel Configurations

The receiver clocking in non-bonded mode varies, depending on whether the rate match FIFO is enabled. When the rate match FIFO is not enabled, the receiver PCS in every channel uses the parallel recovered clock. When the rate match FIFO is enabled, the receiver PCS in every channel uses both the parallel recovered clock and parallel clock from the clock divider.

For Arria V GZ devices, in non-bonded configurations the receiver 10G PCS uses only the parallel clock (recovered) for all its blocks.

Figure 2-29: Three Non-Bonded Receiver Channels without Rate Match FIFO Enabled

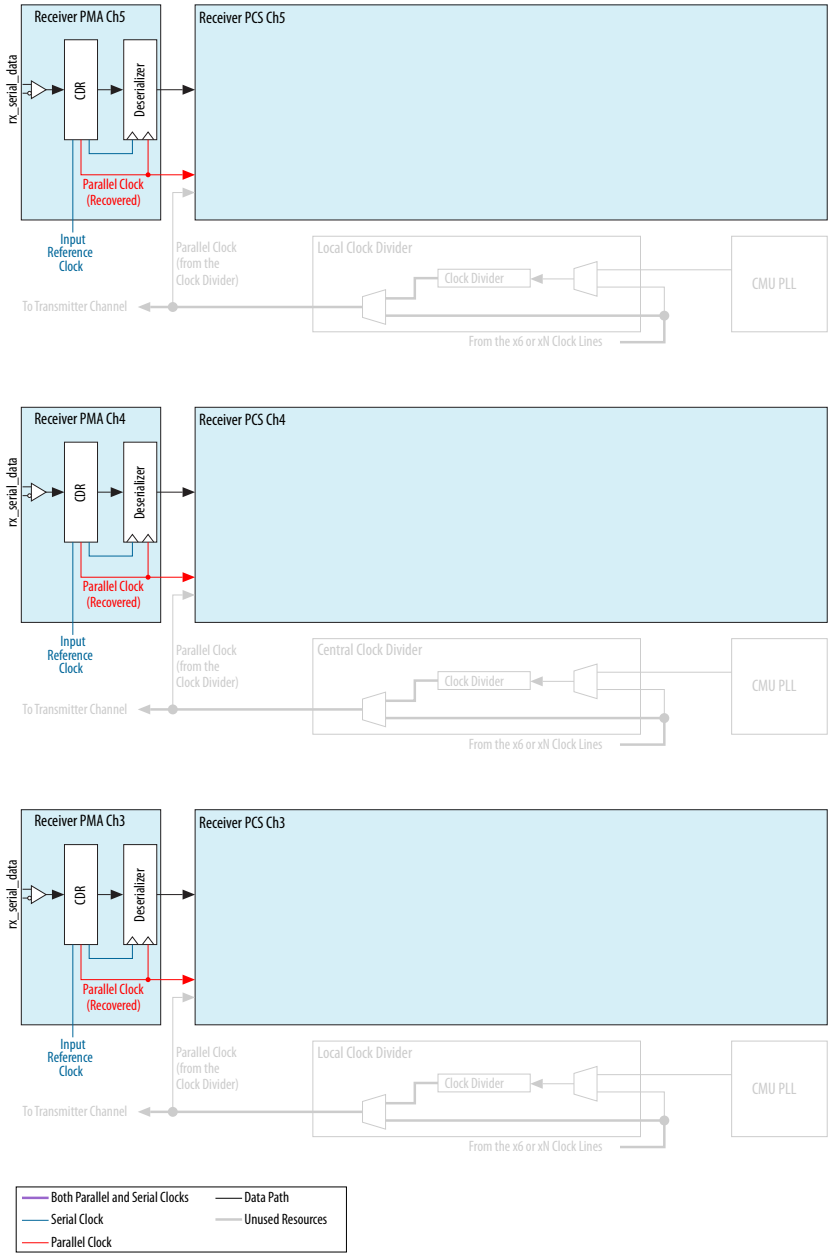


Figure 2-30: Two Non-Bonded Receiver Channels with Rate Match FIFO Enabled

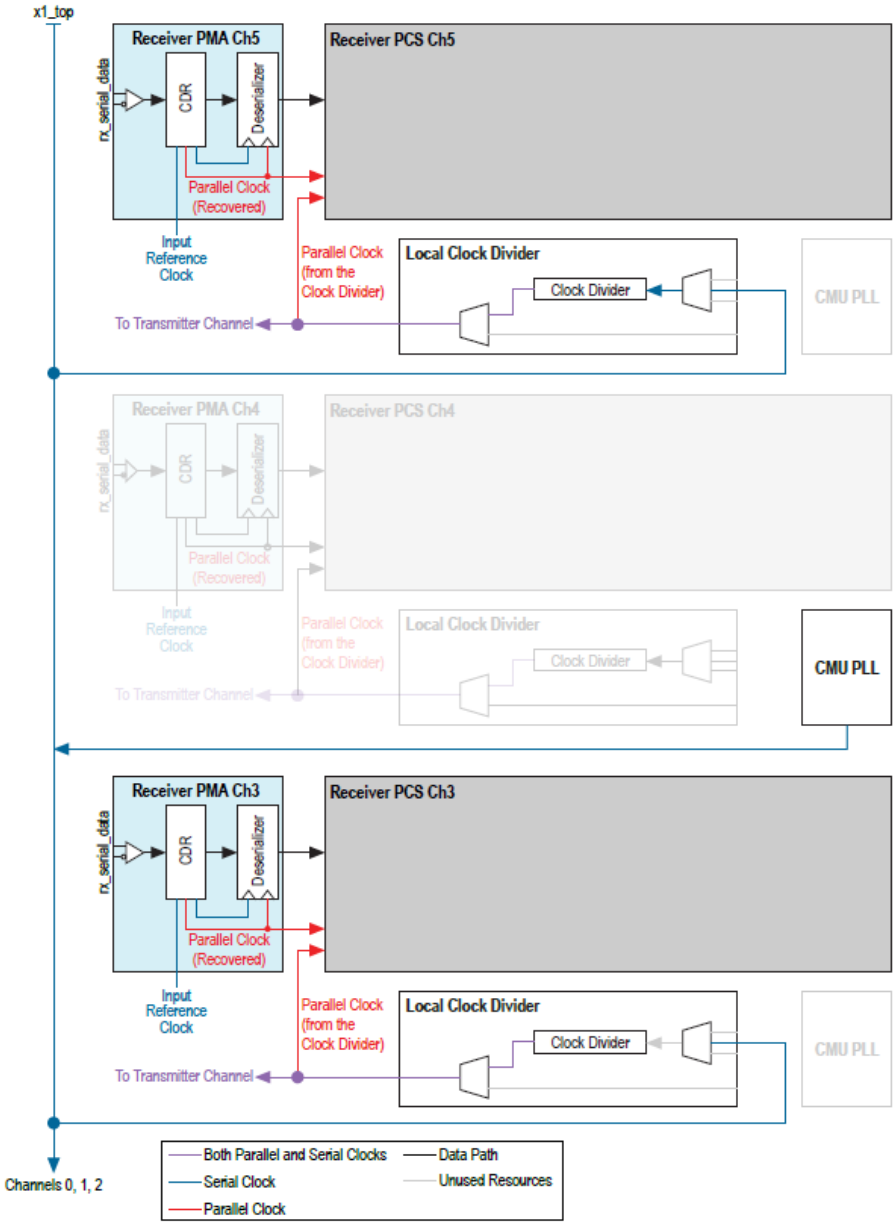

Receiver Bonded Channel Configurations

Receiver channels can only be bonded in configurations where rate match FIFOs are enabled. When bonded, the receiver PCS requires the parallel clock (recovered) and, the parallel clock from the central clock divider in channel 1 or 4.

For Arria V GZ devices, in bonded configurations the receiver 10G PCS uses only the parallel clock (recovered) for all its blocks.

Figure 2-31: Five Bonded Receiver Channels with Rate Match FIFO Enabled

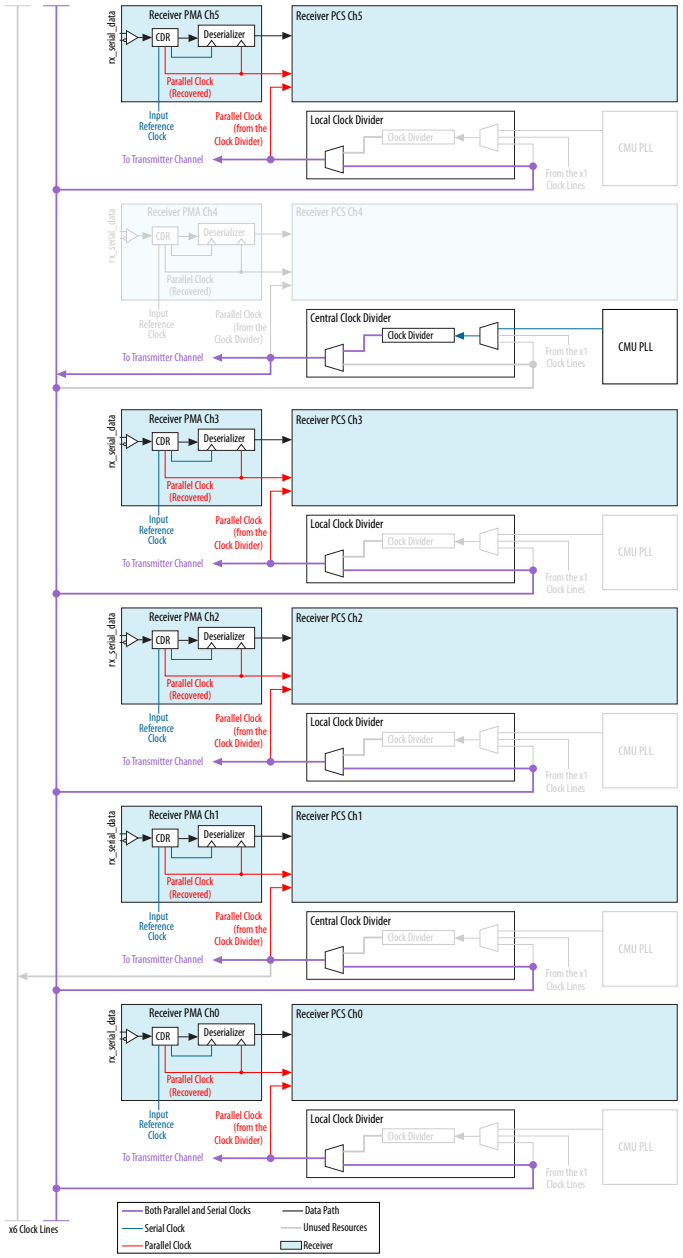

Figure 2-32: Six Bonded Receiver Channels with Rate Match FIFO Enabled Using Fractional PLL

All six channels in the transceiver bank are in a bonded configuration. This configuration is possible because the fractional PLL is used as a transmit PLL instead of a channel PLL in the transceiver bank. Using the fractional PLL enables you to configure the channel PLLs of both channels 1 and 4 as CDRs to perform receiver operations.

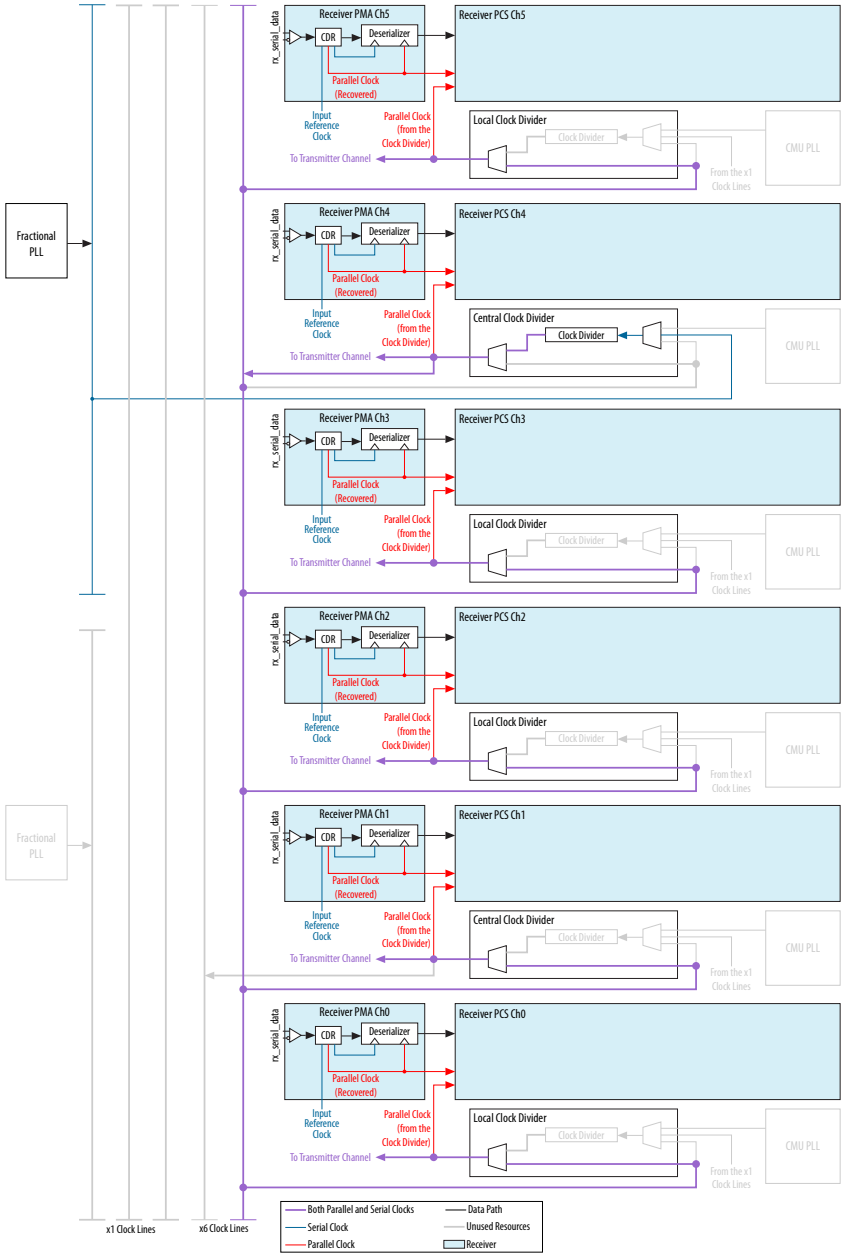

Figure 2-33: Six Channels Configured in Bonded Configuration Using ATX PLL for GZ Devices

All six channels in the transceiver bank in a bonded configuration. Six channel bonding is possible because the ATX PLL is used as a transmitter PLL instead of a channel PLL in the transceiver bank. Using the ATX PLL or fractional PLL allows you to use the channel PLLs of both channels 1 and 4 as CDRs to perform receiver operations.

FPGA Fabric–Transceiver Interface Clocking

This section describes the clocking options available when the transceiver interfaces with the FPGA fabric.

The FPGA fabric–transceiver interface clocks can be subdivided into the following three categories:

- Input reference clocks—Can be an FPGA fabric–transceiver interface clock. This may occur when the FPGA fabric-transceiver interface clock is forwarded to the FPGA fabric, where it can then clock logic.

  Note: The input reference clock can only be routed into the FPGA fabric if a transceiver is also instantiated.
- Transceiver datapath interface clocks—Used to transfer data, control, and status signals between the FPGA fabric and the transceiver channels. The transceiver channel forwards the `tx_clkout` signal to the FPGA fabric to clock the data and control signals into the transmitter. The transceiver channel also forwards the recovered `rx_clkout` clock (in configurations without the rate matcher) or the `tx_clkout` clock (in configurations with the rate matcher) to the FPGA fabric to clock the data and status signals from the receiver into the FPGA fabric.
- Other transceiver clocks—The following transceiver clocks form a part of the FPGA fabric–transceiver interface clocks:
  - `phy_mgmt_clk`—Avalon®-MM interface clock used for controlling the transceivers, dynamic reconfiguration, and calibration
  - `fixed_clk`—the 125 MHz fixed-rate clock used in the PCIe (PIPE) receiver detect circuitry

Table 2-11: FPGA Fabric–Transceiver Interface Clocks

Clock Name	Clock Description	Interface Direction	FPGA Fabric Clock Resource Utilization
tx_pll_refclk, rx_cdr_refclk	Input reference clock used for clocking logic in the FPGA fabric	Transceiver-to-FPGA fabric	GCLK, RCLK, PCLK
tx_clkout, tx_pma_clkout	Clock forwarded by the transceiver for clocking the transceiver datapath interface		
rx_clkout, rx_pma_clkout	Clock forwarded by the receiver for clocking the receiver datapath interface		
tx_coreclkin	User-selected clock for clocking the transmitter datapath interface	FPGA fabric-to-transceiver	
rx_coreclkin	User-selected clock for clocking the receiver datapath interface		
fixed_clk	PCIe receiver detect clock		
phy_mgmt_clk[29]	Avalon-MM interface management clock		

Note:
- For Arria V GZ devices, you can forward the pll_refclk, tx_clkout, and rx_clkout clocks to a fractional PLL so that the fractional PLL can synthesize a clock for the FPGA logic. A second fractional PLL can be reached by periphery clocks, depending on your device and channel placement, and may require using a RGCLK or GCLK.
- For more information about the GCLK, RCLK, and PCLK resources available in each device, refer to the Clock Networks and PLLs in Arria V Devices chapter

Table 2-12: Configuration Specific Port Names for tx_clkout and rx_clkout

Configuration	Port Name for tx_clkout	Port Name for rx_clkout
Custom	tx_clkout	rx_clkout

[29] The phy_mgmt_clk is a free-running clock that is not derived from the transceiver blocks.

Configuration	Port Name for tx_clkout	Port Name for rx_clkout
Native - 10G PCS[30]	tx_10g_clkout	rx_10g_clkout
Native - Standard PCS	tx_std_clkout	rx_std_clkout
Native - PMA Direct	tx_pma_clkout	rx_pma_clkout
Interlaken [30]	tx_clkout	rx_clkout
Low Latency	tx_clkout	rx_clkout
PCIe	pipe_pclk	pipe_pclk
XAUI	xgmii_tx_clk	xgmii_rx_clk

Clock Networks and PLLs in Arria V Devices chapter

Transceiver Datapath Interface Clocking

There are two types of design considerations for clock optimization when interfacing the transceiver datapath to the FPGA fabric:

- PCS with FIFO in phase compensation mode – share clock network for identical channels
- PCS with FIFO in registered mode or PMA direct mode – refer to *AN580: Achieving Timing Closure in Basic (PMA Direct) Functional Mode for additional timing closure techniques between transceiver and FPGA fabric*

Note: For Arria V (GX, GT, ST and SX) devices, the PMA clock for channel 1 and channel 2 of GXB_L0 and GXB_R0 cannot be routed out of the FPGA fabric.

Related Information

AN580: Achieving Timing Closure in Basic (PMA Direct) Functional Mode

Transmitter Datapath Interface Clocking

In 6-Gbps transceivers, the write side of the transmitter phase compensation FIFO makes up the transmitter datapath interface.

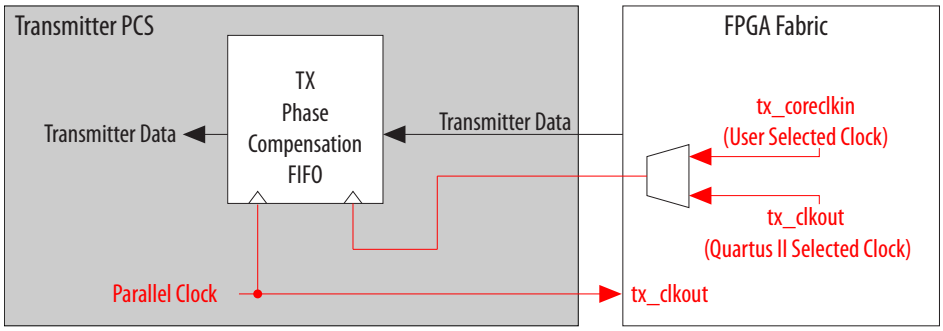
For the 6-Gbps transceivers, the write side of the transmitter phase compensation FIFO makes up the transmitter datapath interface. This interface is clocked with the transmitter datapath interface clock.

The following figure shows the 6-Gbps transmitter datapath interface clocking. The transmitter PCS forwards the following clocks to the FPGA fabric:

- `tx_clkout`—for each transmitter channel in a non-bonded configuration
- `tx_clkout[0]`—for all transmitter channels in a bonded configuration

[30] Available for Arria V GZ devices only.

Figure 2-34: Transmitter Datapath Interface Clocking for 6-Gbps Transceivers

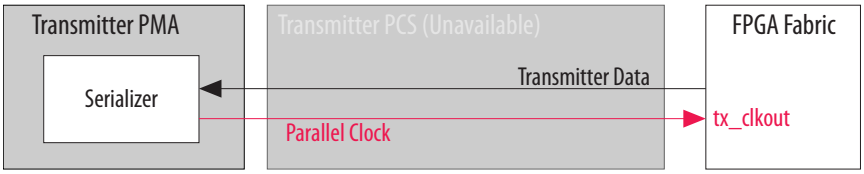


All configurations that use the PCS channel must have a 0 parts per million (ppm) difference between write and read clocks of the transmitter phase compensation FIFO.

For the 10-Gbps transceivers Arria V GT/ST devices, there are no PCS blocks. The only transmit datapath available is a direct connection from the FPGA fabric to the serializer of the transmitter PMA.

The following figure shows the 10-Gbps transmitter datapath interface clocking. For each transmitter channel in a non-bonded configuration, the FPGA fabric forwards the following `tx_clkout` clock to the transmitter PMA.

Figure 2-35: Transmitter Datapath Interface Clocking for 10-Gbps Transceivers (for Arria V GT/ST Devices)



You can clock the transmitter datapath interface by one of the following options:

- The Quartus II-selected transmitter datapath interface clock
- The user-selected transmitter datapath interface clock

Note: To reduce GCLK, RCLK, and PCLK resource utilization in your design, you can select the user-selection option to share the transceiver datapath interface clocks.

  Information about interface clocking for each configuration.

Quartus II-Software Selected Transmitter Datapath Interface Clock

The Quartus II software automatically picks the appropriate clock from the FPGA fabric to clock the transmitter datapath interface.

Figure 2-36: 6-Gbps Transmitter Datapath Interface Clocking for Non-Bonded Channels

The figure shows the transmitter datapath interface of two 6 Gbps transceiver non-bonded channels clocked by their respective transmitter PCS clocks which are forwarded to the FPGA fabric.

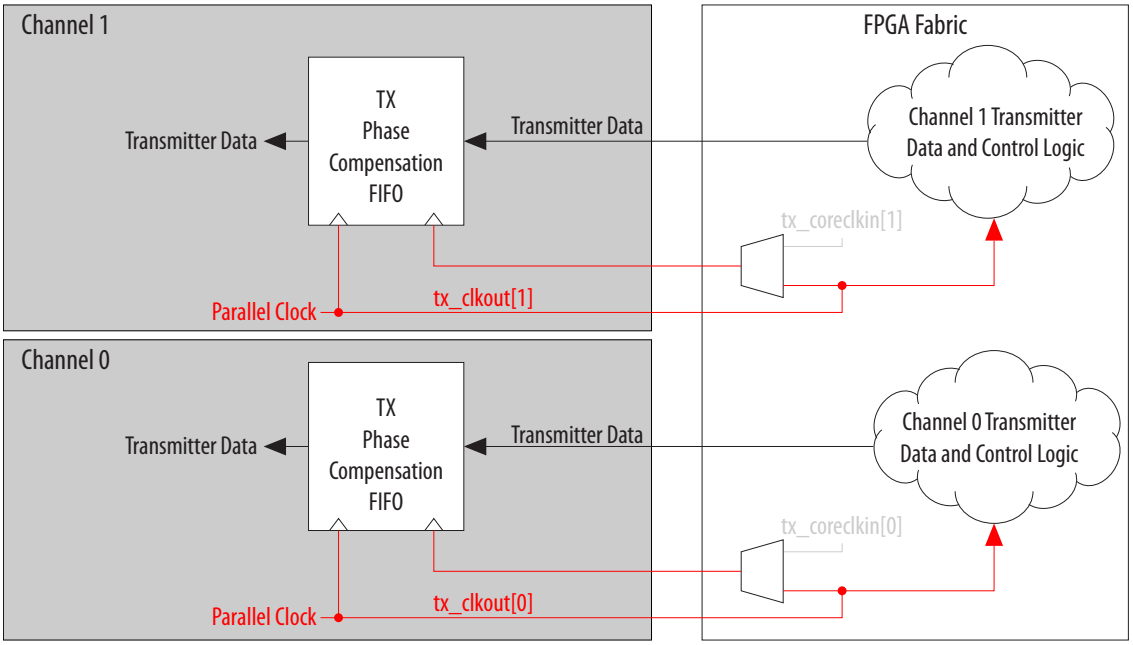

Figure 2-37: Arria V GT/ST 10-Gbps Transmitter Datapath Interface Clocking for Non-Bonded Channels

The figure shows the Arria V GT/ST transmitter datapath interface of two 10-Gbps transceiver non-bonded channels clocked by their respective transmitter PMA clocks, which are forwarded to the FPGA fabric.

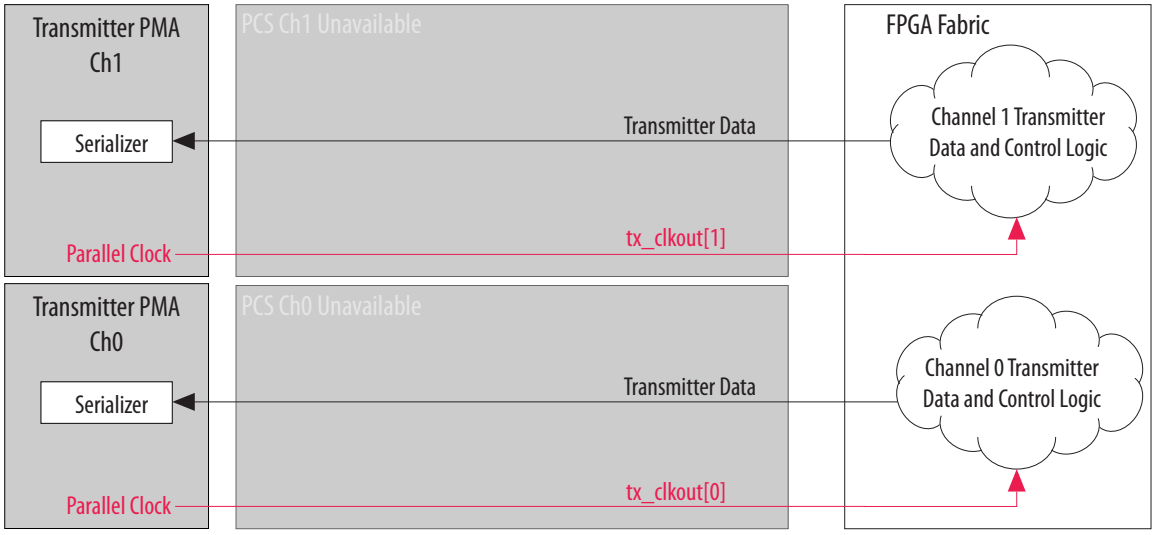

Figure 2-38: 6-Gbps Transmitter Datapath Interface Clocking for Three Bonded Channels

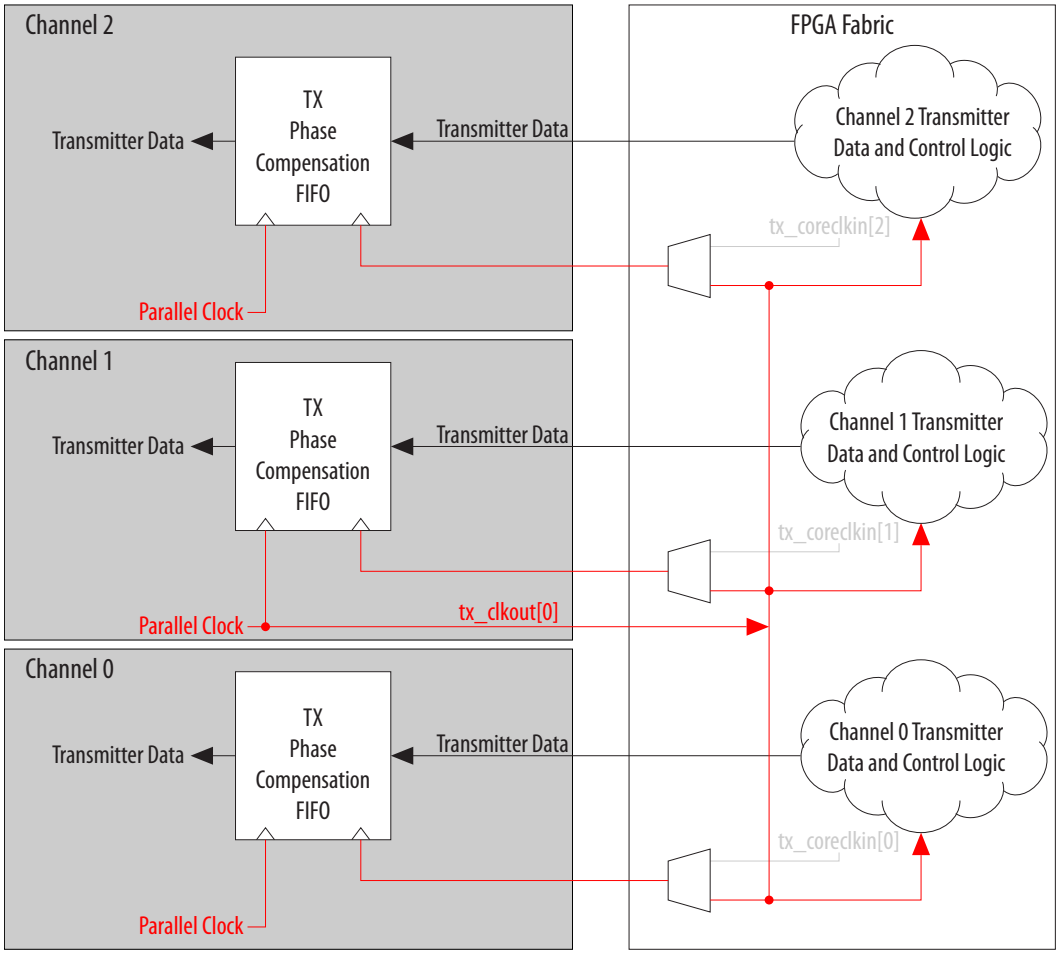
The following figure shows the 6-Gbps transmitter datapath interface of three bonded channels clocked by the `tx_clkout[0]` clock. The `tx_clkout[0]` clock is derived from the central clock divider of channel 1 or 4 in a transceiver bank.



Selecting a Transmitter Datapath Interface Clock

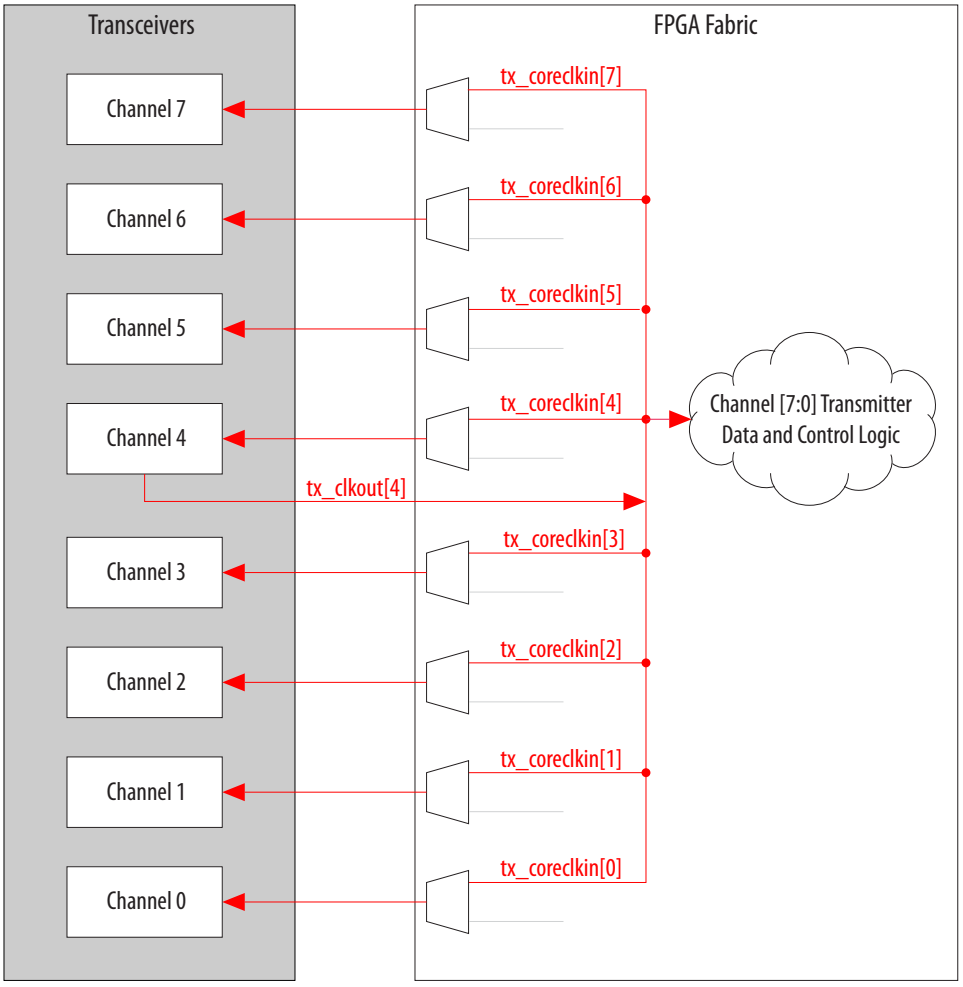
Multiple non-bonded transmitter channels use a large portion of GCLK, RCLK, and PCLK resources. Selecting a common clock driver for the transmitter datapath interface of all identical transmitter channels saves clock resources.

Multiple transmitter channels that are non-bonded lead to high utilization of GCLK, RCLK, and PCLK resources (one clock resource per channel). You can significantly reduce GCLK, RCLK, and PCLK resource use for transmitter datapath clocks if the transmitter channels are identical.

Note: Identical transmitter channels have the same input reference clock source, transmit PLL configuration, transmitter PMA, and PCS configuration, but may have different analog settings, such as transmitter voltage output differential (VOD), transmitter common-mode voltage (VCM), or pre-emphasis.

To achieve the clock resource savings, select a common clock driver for the transmitter datapath interface of all identical transmitter channels. The following figure shows eight identical channels clocked by a single clock (`tx_clkout` of channel 4).

Figure 2-39: Eight Identical Channels with a Single User-Selected Transmitter Interface Clock



To clock eight identical channels with a single clock, perform these steps:

1. Instantiate the `tx_coreclkin` port for all the identical transmitter channels (`tx_coreclkin[7:0]`).
2. Connect `tx_clkout[4]` to the `tx_coreclkin[7:0]` ports.
3. Connect `tx_clkout[4]` to the transmitter data and control logic for all eight channels.

Note: Resetting or powering down channel 4 causes a loss of the clock for all eight channels.

The common clock must have a 0 ppm difference for the read side of the transmitter phase compensation FIFO of all the identical channels. A frequency difference causes the FIFO to under run or overflow, depending on whether the common clock is slower or faster, respectively.

You can drive the 0 ppm common clock by one of the following sources:

- `tx_clkout` of any channel in non-bonded channel configurations
- `tx_clkout[0]` in bonded channel configurations
- Dedicated refclk pins

Note: The Quartus II software does not allow gated clocks or clocks that are generated in the FPGA logic to drive the `tx_coreclkin` ports.

You must ensure a 0 ppm difference. The Quartus II software is unable to ensure a 0 ppm difference because it allows you to use external pins, such as dedicated `refclk` pins.

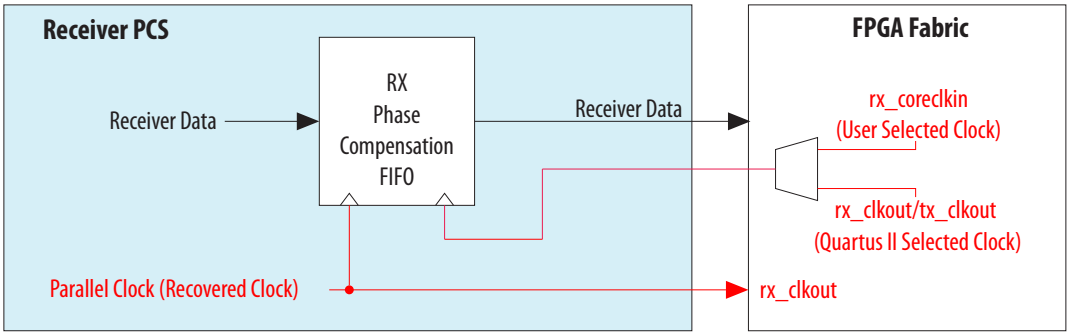
Receiver Datapath Interface Clock

The 6-Gbps receiver datapath interface is comprised of the read side RX phase compensation FIFO.

The read side of the RX phase compensation FIFO makes up the 6-Gbps receiver datapath interface. The receiver datapath interface clock clocks this interface. The receiver PCS forwards the following clocks to the FPGA fabric:

- `rx_clkout`—for each receiver channel in a non-bonded configuration when you do not use a rate matcher
- `tx_clkout`—for each receiver channel in a non-bonded configuration when you use a rate matcher
- `single rx_clkout[0]`—for all receiver channels in a bonded configuration

Figure 2-40: 6-Gbps Receiver Datapath Interface Clocking

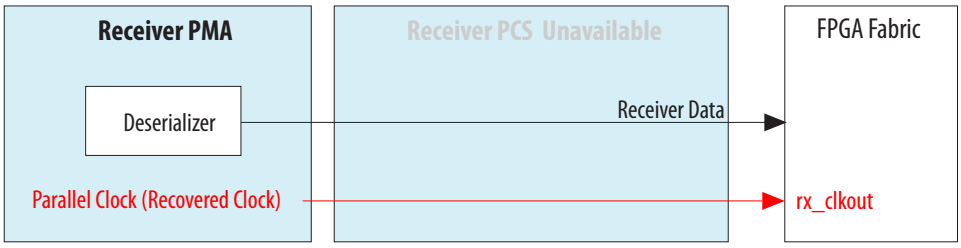


All configurations that use the PCS channel must have a 0 ppm difference between the receiver datapath interface clock and the read side clock of the RX phase compensation FIFO.

For the 10-Gbps transceivers in Arria V GT/ST devices, there are no PCS blocks. The only receiver datapath available is a direct connection from the receiver PMA deserializer to the FPGA fabric.

For each receiver channel in a non-bonded configuration, the receiver PMA forwards the `rx_clkout` clock to the FPGA fabric.

Figure 2-41: Arria V GT/ST 10-Gbps Receiver Datapath Interface Clocking



Note: For more information about interface clocking for each configuration, refer to the Transceiver Custom Configuration in Arria V Devices and Transceiver Protocol Configurations in Arria V Devices chapters.

You can clock the receiver datapath interface by one of the following options:

- The Quartus II-selected receiver datapath interface clock
- The user-selected receiver datapath interface clock

Note: To reduce GCLK, RCLK, and PCLK resource utilization in your design, you can select the user-selection option to share the transceiver datapath interface clocks.

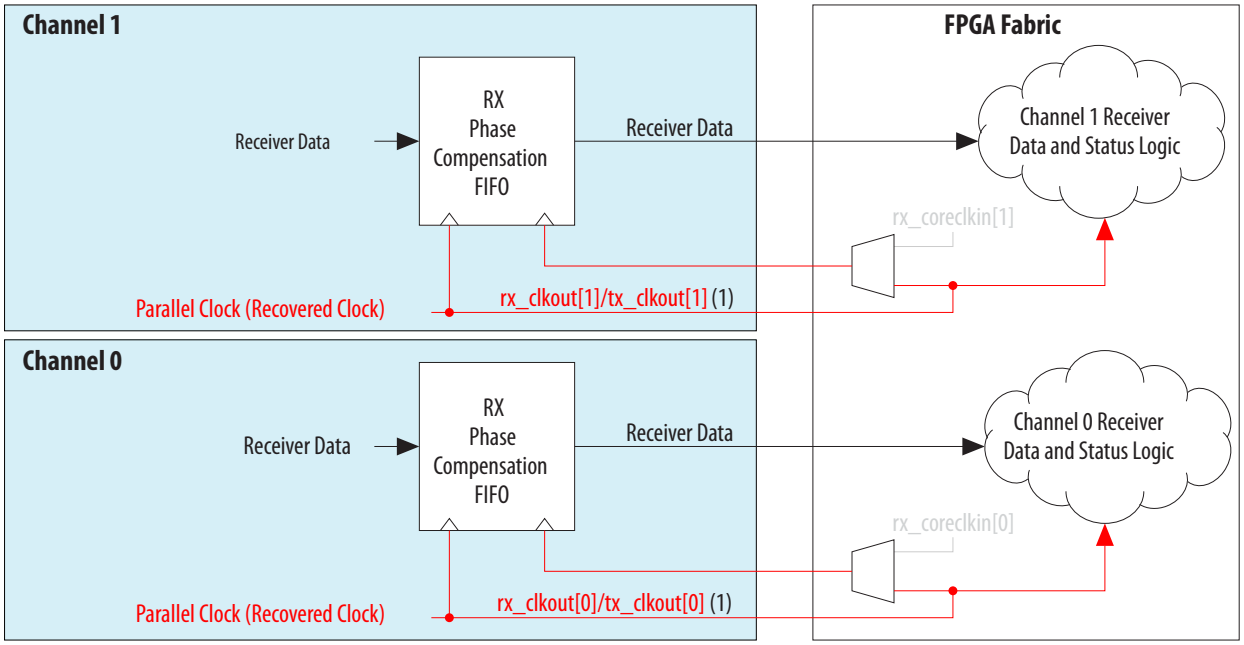
Quartus II Software-Selected Receiver Datapath Interface Clock

Quartus II software automatically picks the appropriate clock from the FPGA fabric to clock the receiver datapath interface.

Figure 2-42: 6-Gbps Receiver Datapath Interface Clocking for Non-Bonded Channels

The figure shows receiver datapath interface of two 6-Gbps transceiver non-bonded channels clocked by their respective receiver PCS clocks, which are forwarded to the FPGA fabric.



Note : (1) If you use a rate matcher, the tx_clkout clock is used.

Figure 2-43: Arria V GT/ST 10-Gbps Receiver Datapath Interface Clocking for Non-Bonded Channels

The figure shows Arria V GT/ST receiver datapath interface of two 10-Gbps transceiver non-bonded channels clocked by their respective receiver CDR recovered PMA clocks, which are forwarded to the FPGA fabric.

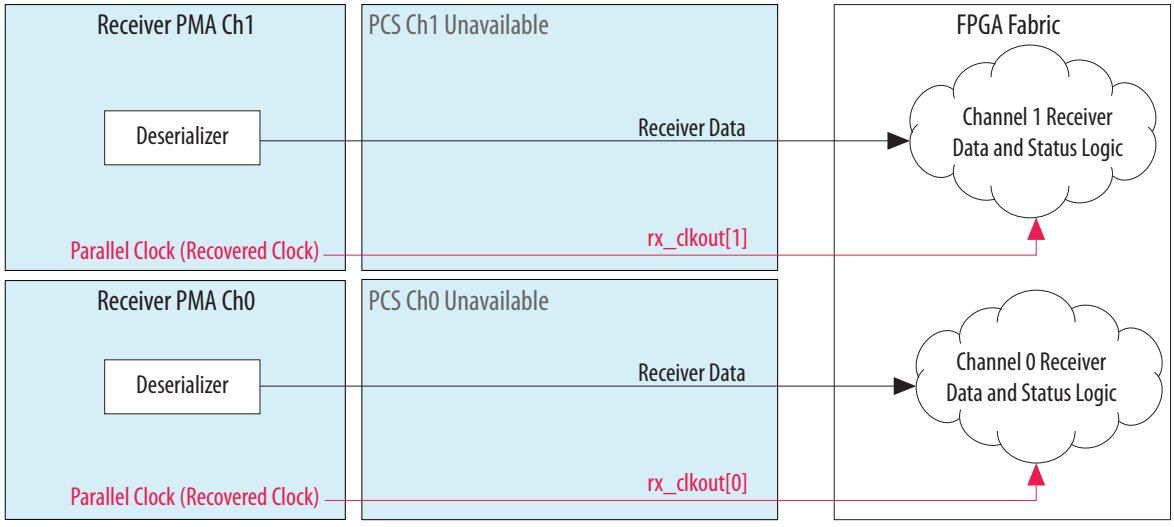


Figure 2-44: 6-Gbps Receiver Datapath Interface Clocking for Three Bonded Channels

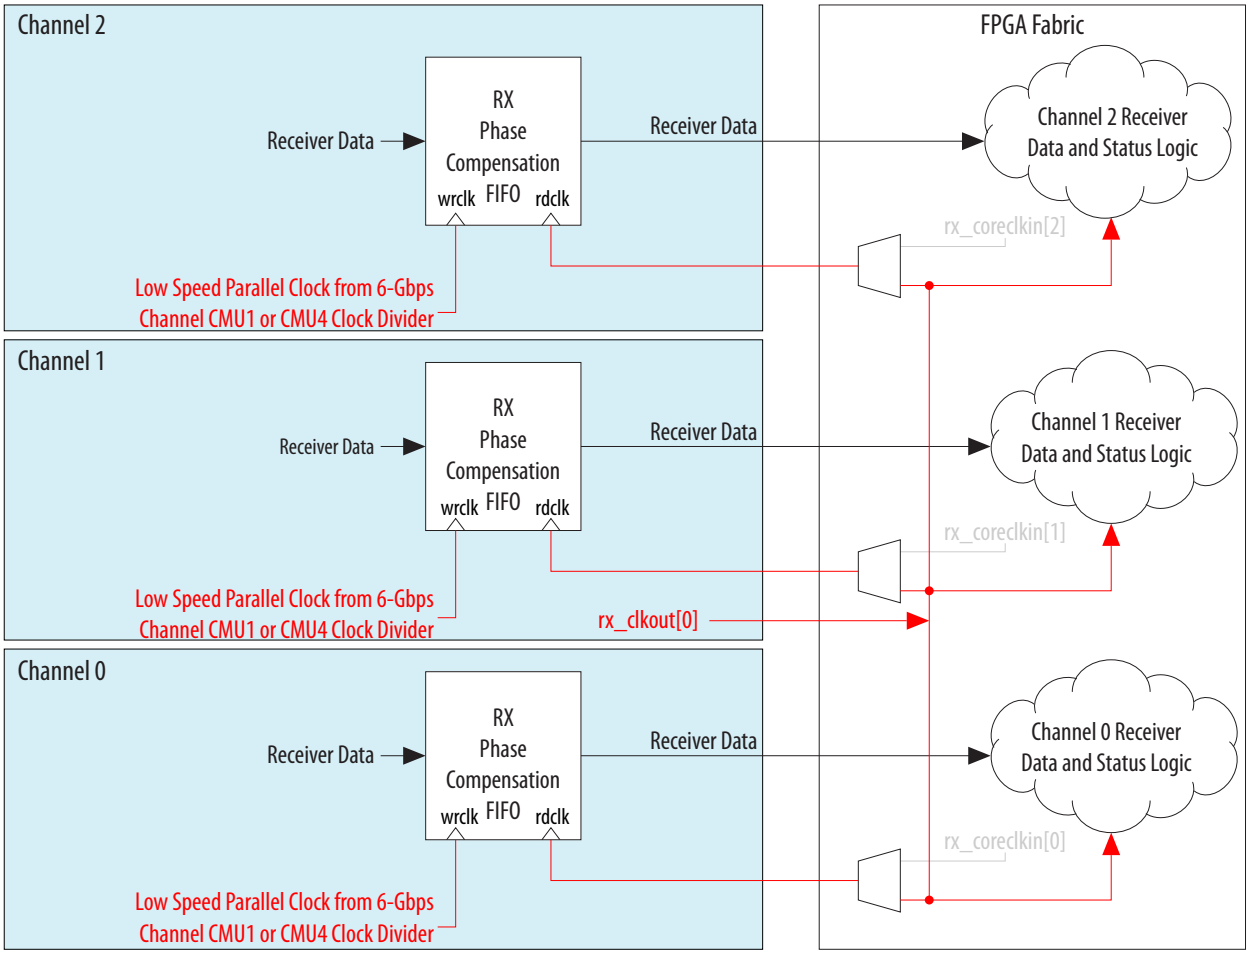
The figure shows the 6-Gbps receiver datapath interface of three bonded channels clocked by the `rx_clkout[0]` clock. The `rx_clkout[0]` clock is derived from the central clock divider of channel 1 or 4 in a transceiver bank.



Selecting a Receiver Datapath Interface Clock

Multiple non-bonded receiver channels use a large portion of GCLK, RCLK, and PCLK resources. Selecting a common clock driver for the receiver datapath interface of all identical receiver channels saves clock resources.

Non-bonded multiple receiver channels lead to high utilization of GCLK, RCLK, and PCLK resources—one clock resource per channel. You can significantly reduce GCLK, RCLK, and PCLK resource use for the receiver datapath clocks if the receiver channels are identical.

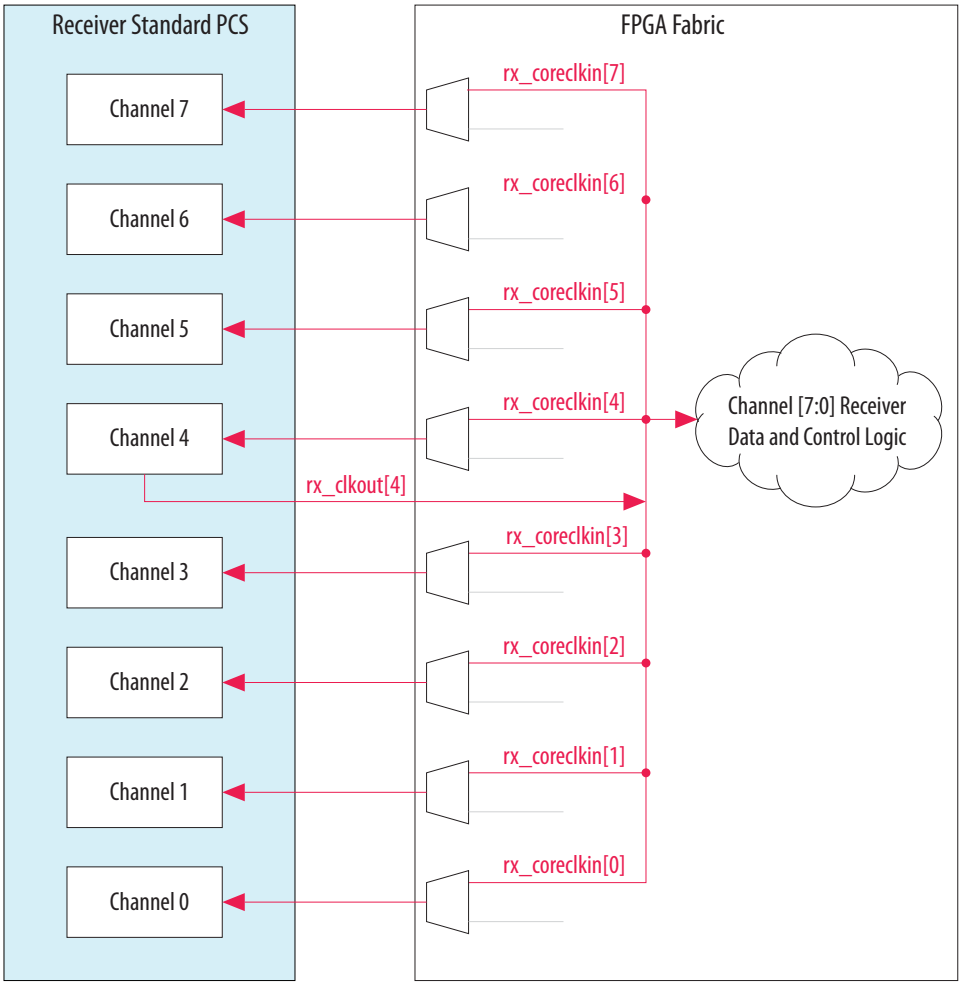
Note: Identical receiver channels are defined as channels that have the same input reference clock source for the CDR and the same receiver PMA and PCS configuration. Identical receiver channels need to be PPM aligned with regards to their remote transmitters. These channels may have different analog settings, such as receiver common mode voltage (V_{ICM}), equalization, or DC gain setting.

To achieve clock resource savings, select a common clock driver for the receiver datapath interface of all identical receiver channels. To select a common clock driver, perform these steps:

1. Instantiate the `rx_coreclkin` port for all the identical receiver channels.
2. Connect the common clock driver to their receiver datapath interface, and receiver data and control logic.

The following figure shows eight identical channels that are clocked by a single clock (`rx_clkout` of channel 4).

Figure 2-45: Eight Identical Channels with a Single User-Selected Receiver Interface Clock



To clock eight identical channels with a single clock, perform these steps:

- Instantiate the `rx_coreclkin` port for all the identical receiver channels (`rx_coreclkin[7:0]`).
- Connect `rx_clkout[4]` to the `rx_coreclkin[7:0]` ports.
- Connect `rx_clkout[4]` to the receiver data and control logic for all eight channels.

Note: Resetting or powering down channel 4 leads to a loss of the clock for all eight channels.

The common clock must have a 0 ppm difference for the write side of the RX phase compensation FIFO of all the identical channels. A frequency difference causes the FIFO to under run or overflow, depending on whether the common clock is faster or slower, respectively.

You can drive the 0 ppm common clock driver from one of the following sources:

- `tx_clkout` of any channel in non-bonded receiver channel configurations with the rate matcher
- `rx_clkout` of any channel in non-bonded receiver channel configurations without the rate matcher
- `tx_clkout[0]` in bonded receiver channel configurations
- Dedicated `refclk` pins

Note: The Quartus II software does not allow gated clocks or clocks generated in the FPGA logic to drive the `rx_coreclkin` ports.

Note: You must ensure a 0 ppm difference. The Quartus II software is unable to ensure a 0 ppm difference because it allows you to use external pins, such as dedicated `refclk` pins.

GXB 0 PPM Core Clock Assignment for GZ Devices

The common clock should have a 0 ppm difference with respect to the read side of the TX FIFO (in the 10G PCS channel) or TX phase compensation FIFO (in the Standard PCS channel) of all the identical channels. A frequency difference causes the FIFO to under-run or overflow, depending on whether the common clock is slower or faster, respectively.

The 0 ppm common clock driver can be driven by one of the following sources:

- `tx_clkout` in non-bonded channel configurations
- `tx_clkout[0]` in bonded channel configurations
- `rx_clkout` in non-bonded channel configurations
- `refclk` when there is 0 PPM difference between `refclk` and `tx_clkout`

Table 2-13: 0 PPM Core Clock Settings

The following table lists the 0 PPM core clock settings that you make in the Quartus II Assignment Editor.

Assignments[31]	Description
To	`tx_dataout/rx_datain pins` of all channels whose `tx/rx_coreclk` ports are connected together and driven by the 0 PPM clock driver.
Assignment Name	0 PPM coreclk setting
Value	ON

Note: For more information about QSF assignments and how 0 PPM is used with various transceiver PHYs, refer to the *Altera Transceiver PHY IP Core User Guide*.

[31] You can find the full hierarchy name of the 0 PPM clock driver using the Node Finder feature in the Quartus II Assignment Editor.

Document Revision History

The table below lists the revision history for this chapter.

Table 2-14: Document Revision History

Date	Version	Changes
March 2015	2015.03.17	Updated the note in the Table "Characteristics of x1, x6, and xN Clock Lines".
September 2014	2014.09.30	• Updated the chapter to indicate that it is not recommended to use fractional PLL in fractional mode as a TX PLL or for PLL cascading. • Modified *Figure: Three Transceiver Bank Channels Bonded Using the PLL Feedback Compensation Path for GZ Devices* to indicate that fPLL does not support PLL feedback compensation when used as a TX PLL.
March 2014	2014.03.07	• Updated the Table "Input Reference Clock Sources". • Updated the Figure "Input Reference Clock Source for CMU PLL Driving Channels with Serial Data Rates Beyond 6.5536 Gbps". • Updated the Table "Characteristics of x1, x6, and xN Clock Lines". • Updated the Figure "Four Bonded Transmitter Channels Driven by fPLL using x6 Clock Line Within a Transceiver Bank" to indicate that when fPLL is used as a transmit PLL, all transceiver channels need to be placed in one transceiver bank. • Updated the tables "Clock Path for Non-Bonded Configurations" and "Clock Path for Bonded Configurations". • Corrected an error in the "Quartus II-Software Selected Transmitter Datapath Interface Clock" section.
October 2013	2013.10.18	• Updated "Input Reference Clocking" section.
May 2013	2013.05.06	• Updated for Quartus II software version 13.0 feature support. • Updated "Input Reference Clocking" section for Arria V GZ devices. • Updated "Internal Clocking" section for Arria V GZ devices. • Updated "FPGA Fabric Transceiver Interface Clocking" section for Arria V GZ devices. • Added link to the known document issues in the Knowledge Base.

Date	Version	Changes
March 2013	2013.03.15	• Updated Table 2-1: Input Reference Clock Sources • Updated Table 2-4: Characteristics of x1, x6, and xN Clock Lines • Updated Figure 2-8: x1 Clock Line Architecture (more than 6.5536 Gbps) • Updated "Transmitter Clock Network".
November 2012	2012.11.19	• Reorganized content and updated template. • Updated for the Quartus II software version 12.1.
June 2012	1.2	• Updated for the Quartus II software version 12.0. • Added basic clocking information from obsoleted “basics” chapter.
November 2011	1.1	Updated chapter for clarity and Quartus II software version 11.1.
August 2011	1.0	Initial release.

Transceiver Reset Control in Arria V Devices

3

2014.09.30

AV53003

Subscribe Send Feedback

Altera's recommended reset sequence ensures that both the physical coding sublayer (PCS) and physical medium attachment (PMA) in each transceiver channel are initialized and functioning correctly.

There are multiple reset options available to reset the analog and digital portions of the transmitter and receiver.

Table 3-1: Available Reset Options

Transceiver PHY IP Core	Embedded Reset Controller	User-Coded Reset Controller	Transceiver PHY Reset Controller IP	Avalon Memory-Mapped Reset Registers
XAUI	X			X
PCIe	X			X
10GBASE-R	X			X
Interlaken For Arria V GZ	X			X

PHY IP Embedded Reset Controller

The embedded reset controller in the PHY IP enables you to initialize the transceiver physical coding sublayer (PCS) and physical medium attachment (PMA) blocks.

To simplify your transceiver-based design, the embedded reset controller provides an option that requires only one control input to implement an automatic reset sequence. Only one embedded reset controller is available for all the channels in a PHY IP instance.

The embedded reset controller automatically performs the entire transceiver reset sequence whenever the `phy_mgmt_clk_reset` signal is triggered. In case of loss-of-link or loss-of-data, the embedded reset controller asserts the appropriate reset signals. You must monitor `tx_ready` and `rx_ready`. A high on these status signals indicates the transceiver is out of reset and ready for data transmission and reception.

Note: Deassert the `mgmt_rst_reset` signal of the transceiver reconfiguration controller at the same time as `phy_mgmt_clk_reset` to start calibration.

Note: You must have a valid and stable ATX PLL reference clock before deasserting the `phy_mgmt_clk_reset` and `mgmt_rst_reset` signals for successful ATX PLL calibration.

ATX PLLs are available in Arria V GZ devices.

Note: The PHY IP embedded reset controller is enabled by default in all transceiver PHY IP cores except the Native PHY IP core.

Embedded Reset Controller Signals

The following figure shows the embedded reset controller and signals in the PHY IP instance. These signals reset your transceiver when you use the embedded reset controller.

Figure 3-1: Embedded Reset Controller

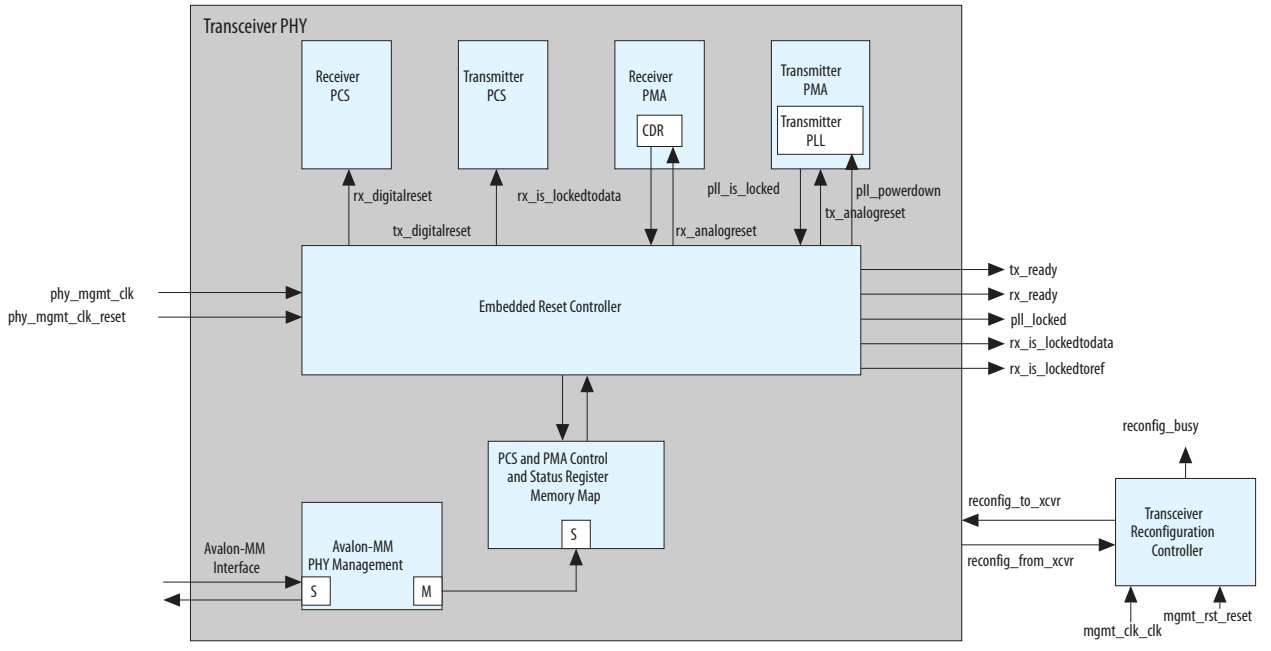

Table 3-2: Embedded Reset Controller Reset Control and Status Signals

Signal Name	Signal	Description
phy_mgmt_clk	Control Input	Clock for the embedded reset controller.
phy_mgmt_clk_reset	Control Input	A high-to-low transition of this asynchronous reset signal initiates the automatic reset sequence control. Hold this signal high to keep the reset signals asserted.
tx_ready	Status Output	A continuous high on this signal indicates that the transmitter (TX) channel is out of reset and is ready for data transmission. This signal is synchronous to phy_mgmt_clk.
rx_ready	Status Output	A continuous high on this signal indicates that the receiver (RX) channel is out of reset and is ready for data reception. This signal is synchronous to phy_mgmt_clk.
reconfig_busy	Status Output	An output from the Transceiver Reconfiguration Controller block indicates the status of the dynamic reconfiguration controller. At the first mgmt_clk_clk clock cycle after power-up, reconfig_busy remains low. This signal is asserted from the second mgmt_clk_clk clock cycle to indicate that the calibration process is in progress . When the calibration process is completed, the reconfig_busy signal is deasserted. This signal is also routed to the embedded reset controller by the Quartus® II software by embedding the signal in the reconfig_to_xcvr bus between the PHY IP and the Transceiver Reconfiguration Controller.
pll_locked	Status Output	This signal is asserted when the TX PLL achieves lock to the input reference clock. When this signal is asserted high, the embedded reset controller deasserts the tx_digitalreset signal.
rx_is_lockedtodata	Status Output	This signal is an optional output status port. When asserted, this signal indicates that the CDR is locked to the RX data and the CDR has changed from lock-to-reference (LTR) to lock-to-data (LTD) mode.
rx_is_lockedtoref	Status Output	This is an optional output status port. When asserted, this signal indicates that the CDR is locked to the reference clock.
mgmt_clk_clk	Clock	Clock for the Transceiver Reconfiguration Controller. This clock must be stable before releasing mgmt_rst_reset.

Signal Name	Signal	Description
mgmt_rst_reset	Reset	Reset for the Transceiver Reconfiguration Controller

Resetting the Transceiver with the PHY IP Embedded Reset Controller During Device Power-Up

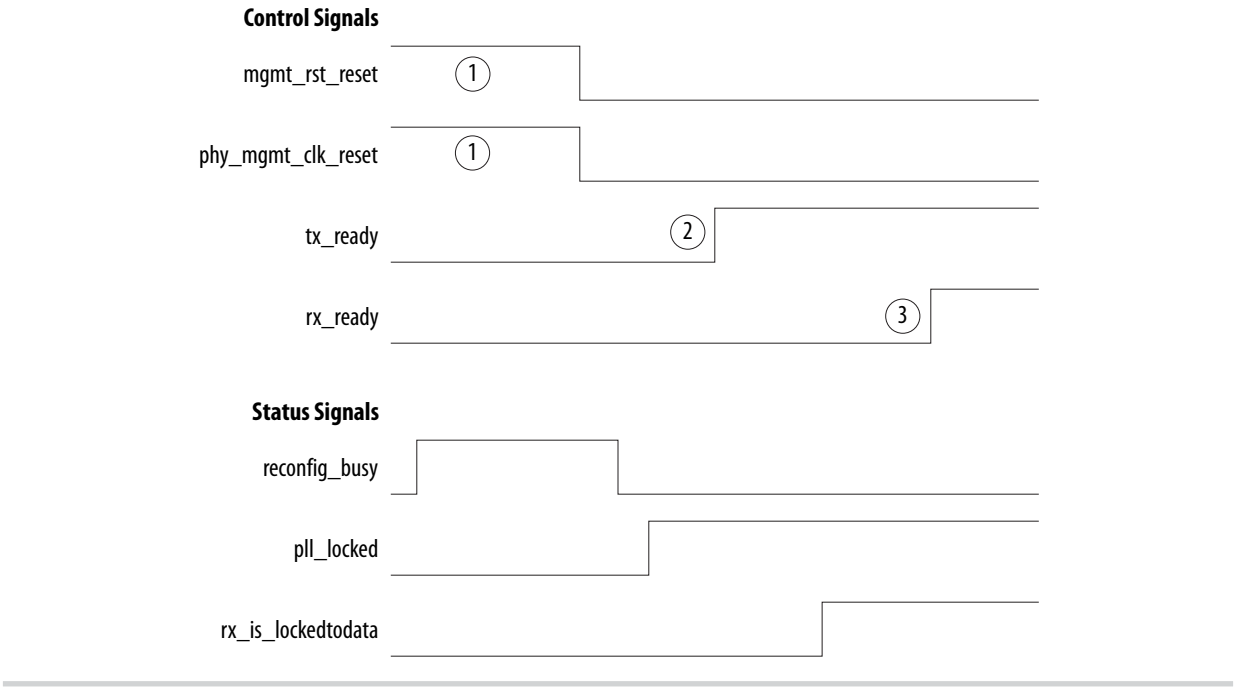
Follow this reset sequence to ensure a reliable link initialization after the initial power-up.

The numbers in the following figure correspond to the following numbered list, which guides you through the transceiver reset sequence during device power-up.

1. During device power-up, `mgmt_rst_reset` and `phy_mgmt_clk_reset` must be asserted to initialize the reset sequence. `phy_mgmt_clk_reset` holds the transceiver blocks in reset and `mgmt_rst_reset` is required to start the calibration IPs. Both these signals should be held asserted for a minimum of two `phy_mgmt_clk` clock cycles. If `phy_mgmt_clk_reset` and `mgmt_rst_reset` are driven by the same source, deassert them at the same time. If the two signals are not driven by the same source, `phy_mgmt_clk_reset` must be deasserted before `mgmt_rst_reset`.
2. After the transmitter calibration and reset sequence are complete, the `tx_ready` status signal is asserted and remains asserted to indicate that the transmitter is ready to transmit data.
3. After the receiver calibration and reset sequence are complete, the `rx_ready` status signal is asserted and remains asserted to indicate that the receiver is ready to receive data.

Note: If the `tx_ready` and `rx_ready` signals do not stay asserted, the reset sequence did not complete successfully and the link will be down.

Figure 3-2: Reset Sequence Timing Diagram Using Embedded Reset Controller during Device Power-Up



Resetting the Transceiver with the PHY IP Embedded Reset Controller During Device Operation

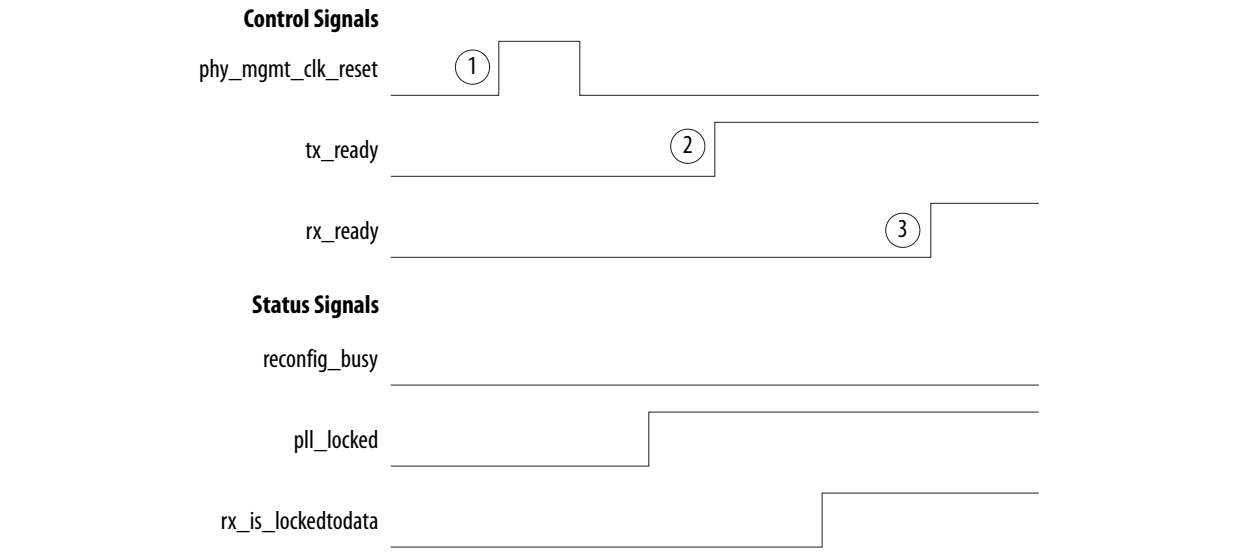
Follow this reset sequence to reset the entire transceiver at any point during the device operation, to re-establishing a link, or after certain dynamic reconfigurations.

The numbers in the following figure correspond to the numbered list, which guides you through the transceiver reset sequence during device operation.

1. Assert `phy_mgmt_clk_reset` for two `phy_mgmt_clk` clock cycles to re-start the entire transceiver reset sequence.
2. After the transmitter reset sequence is complete, the `tx_ready` status signal is asserted and remains asserted to indicate that the transmitter is ready to transmit data.
3. After the receiver reset sequence is complete, the `rx_ready` status signal is asserted and remains asserted to indicate that the receiver is ready to receive data.

Note: If the `tx_ready` and `rx_ready` signals do not stay asserted, the reset sequence did not complete successfully and the link will be down.

Figure 3-3: Reset Sequence Timing Diagram Using Embedded Reset Controller during Device Operation



Note: To reset the transmitter and receiver analog and digital blocks separately without repeating the entire reset sequence, use the Avalon Memory Map registers.

User-Coded Reset Controller

You must implement external reset controller logic (user-coded reset controller) if you disable the embedded reset controller to initialize the transceiver physical coding sublayer (PCS) and physical medium attachment (PMA) blocks.

You can implement a user-coded reset controller with one of the following:

- Using your own Verilog/VHDL code to implement the reset sequence
- Using the Quartus II IP Catalog, which provides a ready-made reset controller IP to place your own Verilog/VHDL code

When using manual mode, you must create a user-coded reset controller to manage the input signals.

Note: You must disable the embedded reset controller before using the user-coded reset controller.

Note: The embedded reset controller can only be disabled for non-protocol transceiver PHY IPs, such as 10GBASE-R PHY, custom PHY, low latency PHY and deterministic latency PHY. Native PHY IP does not have an embedded reset controller, so you must implement your own reset logic.

If you implement your own reset controller, consider the following:

- The user-coded reset controller must be level sensitive (active high)
- The user-coded reset controller does not depend on `phy_mgmt_clk_reset`
- You must provide a clock and reset to the reset controller logic
- The internal signals of the PHY IP embedded reset controller are configured as ports
- You can hold the transceiver channels in reset by asserting the appropriate reset control signals

Note: You must have a valid and stable ATX PLL reference clock before deasserting the `pll_powerdown` and `mgmt_rst_reset` signals for successful ATX PLL calibration.

ATX PLLs are available in Arria V GZ devices.

User-Coded Reset Controller Signals

Use the signals in the following figure and table with a user-coded reset controller.

Figure 3-4: Interaction Between the Transceiver PHY Instance, Transceiver Reconfiguration Controller, and the User-Coded Reset Controller

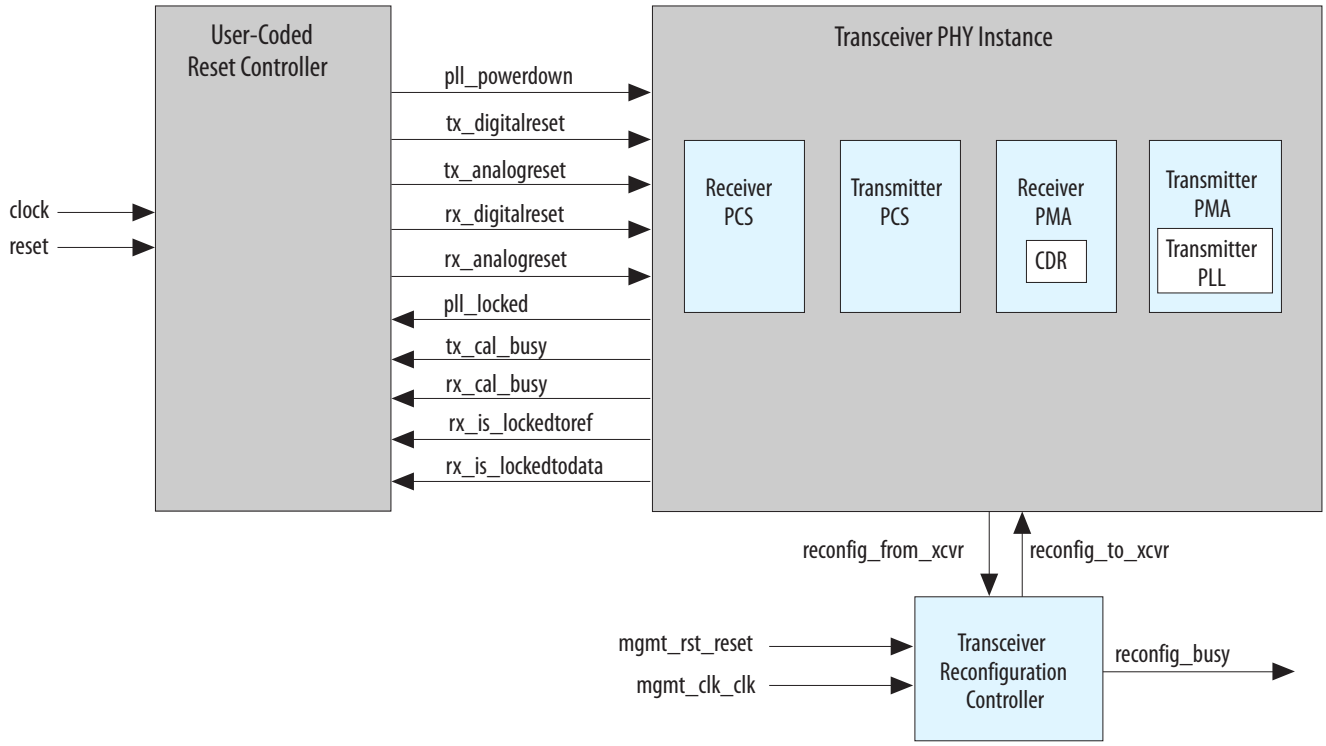

Table 3-3: Signals Used by the Transceiver PHY instance, Transceiver Reconfiguration Controller, and User-Coded Reset Controller

Signal Name	Signal Type	Description
mgmt_clk_clk	Clock	Clock for the Transceiver Reconfiguration Controller. This clock must be stable before releasing mgmt_rst_reset.
mgmt_rst_reset	Reset	Reset for the Transceiver Reconfiguration Controller
pll_powerdown	Control	Resets the TX PLL when asserted high
tx_analogreset	Control	Resets the TX PMA when asserted high
tx_digitalreset	Control	Resets the TX PCS when asserted high
rx_analogreset	Control	Resets the RX PMA when asserted high
rx_digitalreset	Control	Resets the RX PCS when asserted high
reconfig_busy	Status	A high on this signal indicates that reconfiguration is active
tx_cal_busy	Status	A high on this signal indicates that TX calibration is active
rx_cal_busy	Status	A high on this signal indicates that RX calibration is active

Signal Name	Signal Type	Description
pll_locked	Status	A high on this signal indicates that the TX PLL is locked
rx_is_lockedtoref	Status	A high on this signal indicates that the RX CDR is in the lock to reference (LTR) mode
rx_is_lockedtodata	Status	A high on this signal indicates that the RX CDR is in the lock to data (LTD) mode

Resetting the Transmitter with the User-Coded Reset Controller During Device Power-Up

Follow this reset sequence when designing your User-Coded Reset Controller to ensure a reliable transmitter initialization after the initial power-up.

The numbers in the figure correspond to the following numbered list, which guides you through the transmitter reset sequence during device power-up.

1. To reset the transmitter, begin with:
   - Assert `mgmt_rst_reset` at power-up to start the calibration IPs. Hold `mgmt_rst_reset` active for a minimum of two reset controller clock cycles.
   - Assert and hold `pll_powerdown`, `tx_analogreset`, and `tx_digitalreset` at power-up to reset the transmitter. You can deassert `tx_analogreset` at the same time as `pll_powerdown`.
   - Assert `pll_powerdown` for a minimum duration of 1 µs ($t_{pll\_powerdown}$). If you use ATX PLL calibration (available in Arria V GZ devices), deassert `pll_powerdown` before `mgmt_rst_reset` so that the ATX PLL is not powered down during calibration. Otherwise, `pll_powerdown` can be deasserted anytime after `mgmt_rst_reset` is deasserted.
   - Make sure there is a stable reference clock to the PLL before deasserting `pll_powerdown` and `mgmt_rst_reset`.
2. After the transmitter PLL locks, the `pll_locked` status gets asserted after t_{pll_lock}.
3. After the transmitter calibration completes, the `tx_cal_busy` status is deasserted. Depending on the transmitter calibrations, this could happen before or after the `pll_locked` is asserted.
4. Deassert `tx_digitalreset` after the gating conditions occur for a minimum duration of $t_{tx\_digitalreset}$. The gating conditions are:
   - `pll_powerdown` is deasserted
   - `pll_locked` is asserted
   - `tx_cal_busy` is deasserted

The transmitter is out of reset and ready for operation.

Note: During calibration, `pll_locked` might assert and deassert as the calibration IP runs.

Figure 3-5: Reset Sequence Timing Diagram for Transmitter using the User-Coded Reset Controller during Device Power-Up

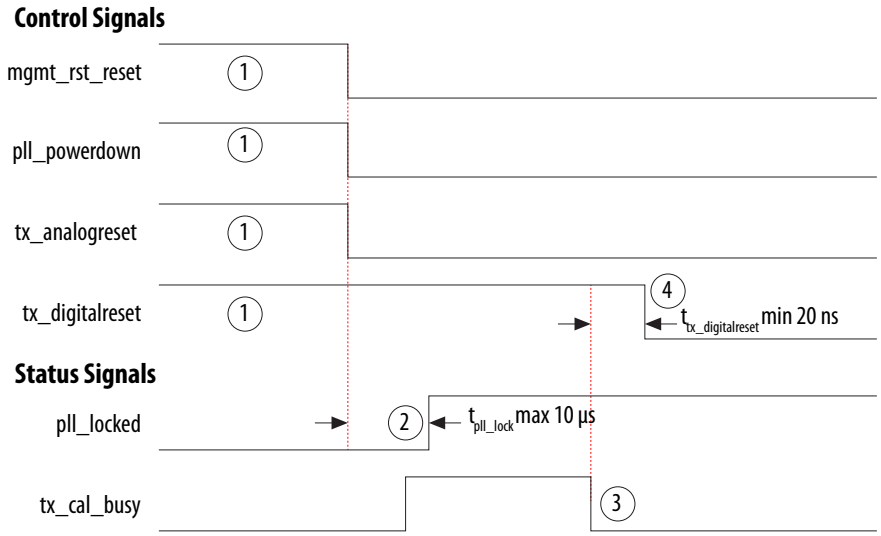

Table 3-4: Guidelines for Resetting the PLL, TX PMA, and TX PCS

To Reset	You Must Reset

PLL	`pll_powerdown`
	`tx_analogreset`
	`tx_digitalreset`

TX PMA	`tx_analogreset` `tx_digitalreset`
TX PCS	`tx_digitalreset`

Resetting the Transmitter with the User-Coded Reset Controller During Device Operation

Follow this reset sequence if you want to reset the PLL, or analog or digital blocks of the transmitter at any point during device operation. This might be necessary for re-establishing a link or after certain dynamic reconfigurations.

The numbers in the following figure correspond to the following numbered list, which guides you through the transmitter reset sequence during device operation.

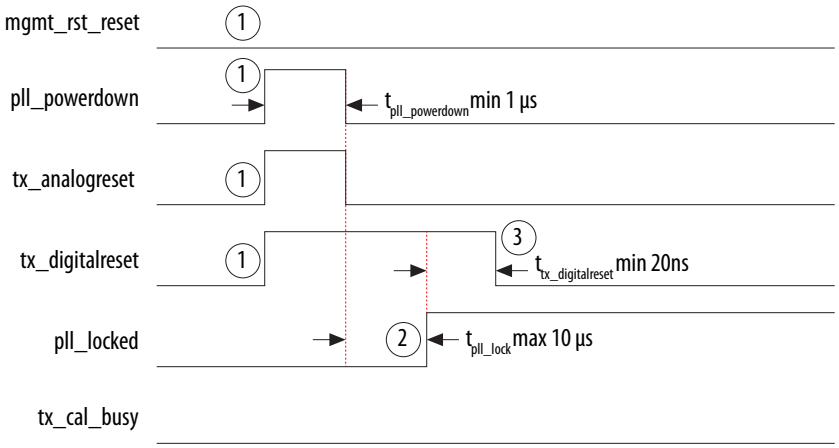
1. To reset the transmitter:

- Assert `pll_powerdown`, `tx_analogreset` and `tx_digitalreset`. `tx_digitalreset` must be asserted every time `pll_powerdown` and `tx_analogreset` are asserted to reset the PCS blocks.
- Hold `pll_powerdown` asserted for a minimum duration of $t_{pll\_powerdown}$.
- Deassert `tx_analogreset` at the same time or after `pll_powerdown` is deasserted.

2. After the transmitter PLL locks, the `pll_locked` status is asserted after t_{pll_lock}. While the TX PLL locks, the `pll_locked` status signal may toggle. It is asserted after t_{pll_lock}.
3. Deassert `tx_digitalreset` after a minimum duration of $t_{tx\_digitalreset}$, and after all the gating conditions are removed:

- `pll_powerdown` is deasserted
- `pll_locked` is deasserted
- `tx_cal_busy` is deasserted

Figure 3-6: Reset Sequence Timing Diagram for Transmitter using the User-Coded Reset Controller during Device Operation



Resetting the Receiver with the User-Coded Reset Controller During Device Power-Up Configuration

Follow this reset sequence to ensure a reliable receiver initialization after the initial power-up.

The numbers in the following figure correspond to the following numbered list, which guides you through the receiver reset sequence during device power-up.

1. Assert `mgmt_rst_reset` at power-up to start the calibration IPs. Hold `mgmt_rst_reset` active for a minimum of two `mgmt_clk_clock` cycles. Hold `rx_analogreset` and `rx_digitalreset` active at power-up to hold the receiver in reset. You can deassert them after all the gating conditions are removed.
2. After the receiver calibration completes, the `rx_cal_busy` status is deasserted.
3. Deassert `rx_analogreset` after a minimum duration of $t_{rx\_analogreset}$ after `rx_cal_busy` is deasserted.
4. `rx_is_lockedtodata` is a status signal from the receiver CDR indicating that the CDR is in the lock to data (LTD) mode. Ensure `rx_is_lockedtodata` is asserted and stays asserted for a minimum duration

of t_{LTD} before deasserting `rx_digitalreset`. If `rx_is_lockedtodata` is asserted and toggles, you must wait another additional t_{LTD} duration before deasserting `rx_digitalreset`.

5. Deassert `rx_digitalreset` after a minimum duration of t_{LTD} after `rx_is_lockedtodata` stays asserted. Ensure `rx_analogreset` and `rx_cal_busy` are deasserted before deasserting `rx_digitalreset`.

The receiver is now out of reset and ready for operation.

Note: `rx_is_lockedtodata` might toggle when there is no data at the receiver input.

Note: `rx_is_lockedtoref` is a don't care when `rx_is_lockedtodata` is asserted.

Note: `rx_analogreset` must always be followed by `rx_digitalreset`.

Figure 3-7: Reset Sequence Timing Diagram for Receiver using the User-Coded Reset Controller during Device Power-Up

Resetting the Receiver with the User-Coded Reset Controller During Device Operation

Follow this reset sequence to reset the analog or digital blocks of the receiver at any point during the device operation. This might be necessary for re-establishing a link or after certain dynamic reconfigurations.

The numbers in the following figure correspond to the following numbered list, which guides you through the receiver reset sequence during device operation.

1. Assert `rx_analogreset` and `rx_digitalreset` at any point independently. However, you must assert `rx_digitalreset` every time `rx_analogreset` is asserted to reset the PCS blocks.
2. Deassert `rx_analogreset` after a minimum duration of 40 ns ($t_{rx\_analogreset}$).
3. `rx_is_lockedtodata` is a status signal from the receiver CDR that indicates that the CDR is in the lock to data (LTD) mode. Ensure `rx_is_lockedtodata` is asserted and stays asserted before deasserting `rx_digitalreset`.
4. Deassert `rx_digitalreset` after a minimum duration of t_{LTD} after `rx_is_lockedtodata` stays asserted. Ensure `rx_analogreset` is deasserted.

Note: `rx_is_lockedtodata` might toggle when there is no data at the receiver input. `rx_is_lockedtoref` is a don't care when `rx_is_lockedtodata` is asserted.

Transceiver Reset Using Avalon Memory Map Registers

You can use Memory Map registers within the PHY IP instance to control the reset signals through the Avalon Memory Map interface.

This gives the flexibility of resetting the PLL, and transmitter and receiver analog and digital blocks separately without repeating the entire reset sequence.

Transceiver Reset Control Signals Using Avalon Memory Map Registers

The following table lists the memory map registers for CDR lock mode and channel reset. These signals help you reset your transceiver when you use Memory Map registers within the PHY IP.

Table 3-5: Transceiver Reset Control Using Memory Map Registers

Register Name	Description
pma_rx_set_locktodata	This register is for CDR manual lock mode only. When you set the register to high, the RX CDR PLL is in the lock to data (LTD) mode. The default is low when both registers have the CDR in auto lock mode.
pma_rx_set_locktoref	This register is for CDR manual lock mode only. When you set the register to high, the RX CDR PLL is in the lock to reference (LTR) mode if pma_rx_set_lockedtodata is not asserted. The default is low when both registers have the CDR in auto lock mode.
reset_tx_digital	When you set this register to high, the tx_digitalreset signal is asserted in every channel that is enabled for reset control through the reset_ch_bitmask register. To deassert the tx_digitalreset signal, set the reset_tx_digital register to 0.
reset_rx_analog	When you set this register to high, the rx_analogreset signal is asserted in every channel that is enabled for reset control through the reset_ch_bitmask register. To deassert the rx_analogreset signal, set the reset_rx_analog register to 0.
reset_rx_digital	When you set this register to high, the rx_digitalreset signal is asserted in every channel that is enabled for reset control through the reset_ch_bitmask register. To deassert the rx_digitalreset signal, set the reset_rx_digital register to 0.
reset_ch_bitmask	The registers provide an option to enable or disable certain channels in a PHY IP instance for reset control. By default, all channels in a PHY IP instance are enabled for reset control.
pll_powerdown	When asserted, the TX phase-locked loop (PLL) is turned off.

Clock Data Recovery in Manual Lock Mode

Use the clock data recovery (CDR) manual lock mode to override the default CDR automatic lock mode depending on your design requirements.

The two control signals to enable and control the CDR in manual lock mode are rx_set_locktoref and rx_set_locktodata.

Related Information

"Transceiver PHY Reset Controller IP Core" chapter of the Altera Transceiver PHY IP Core User Guide.

Refer to the description of the `rx_digitalreset` signal in the "Top-Level Signals" table for information about using the manual lock mode.

Control Settings for CDR Manual Lock Mode

Use the following control settings to set the CDR lock mode:

Table 3-6: Control Settings for the CDR in Manual Lock Mode

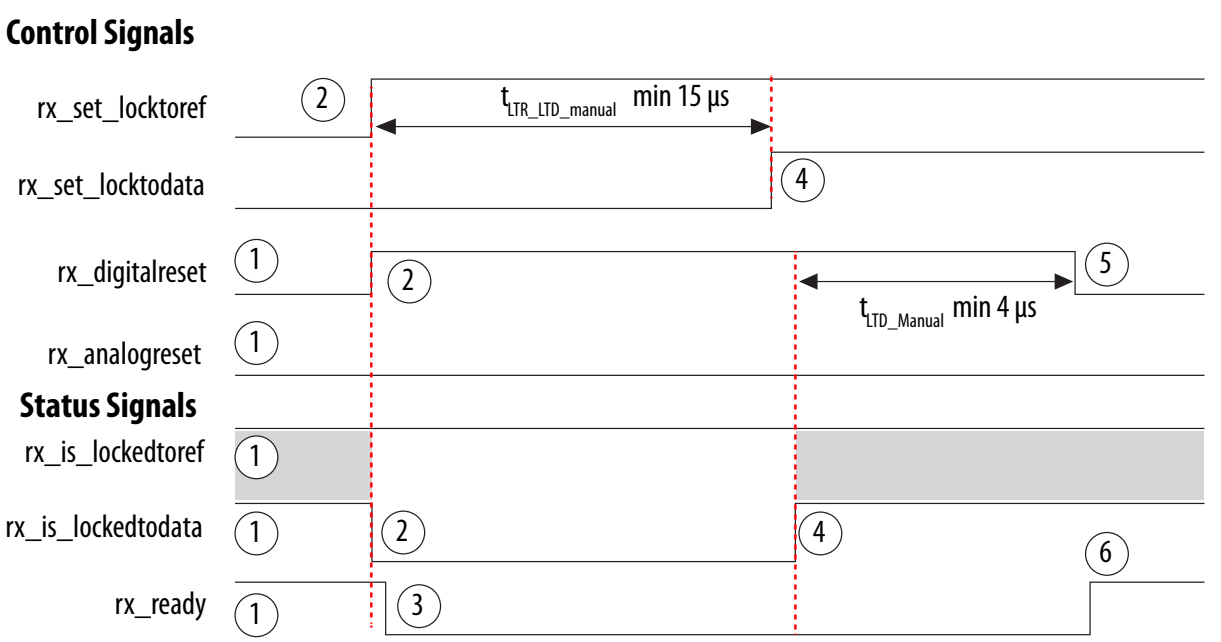
rx_set_locktoref	rx_set_locktodata	CDR Lock Mode
0	0	Automatic
1	0	Manual-RX CDR LTR
X	1	Manual-RX CDR LTD

Resetting the Transceiver in CDR Manual Lock Mode

The numbers in this list correspond to the numbers in the following figure, which guides you through the steps to put the CDR in manual lock mode.

1. Make sure that the calibration is complete (`rx_cal_busy` is low) and the transceiver goes through the initial reset sequence. The `rx_digitalreset` and `rx_analogreset` signals should be low. The `rx_is_lockedtoref` is a don't care and can be either high or low. The `rx_is_lockedtodata` and `rx_ready` signals should be high, indicating that the transceiver is out of reset. Alternatively, you can start directly with the CDR in manual lock mode after the calibration is complete.
2. Assert the `rx_set_locktoref` signal high to switch the CDR to the lock-to-reference mode. The `rx_is_lockedtodata` status signal is deasserted. Assert the `rx_digitalreset` signal high at the same time or after `rx_set_lockedtoref` is asserted if you use the user-coded reset. When the Transceiver PHY reset controller is used, the `rx_digitalreset` is automatically asserted.
3. After the `rx_digitalreset` signal gets asserted, the `rx_ready` status signal is deasserted.
4. Assert the `rx_set_locktodata` signal high after $t_{LTR\_LTD\_manual}$ to switch the CDR to the lock-to-data mode. The `rx_is_lockedtodata` status signal gets asserted, which indicates that the CDR is now set to LTD mode. The `rx_is_lockedtoref` status signal can be a high or low and can be ignored.
5. Deassert the `rx_digitalreset` signal after t_{LTD_Manual}.
6. After the `rx_digitalreset` signal is deasserted, the `rx_ready` status signal gets asserted if you are using the Transceiver PHY Reset Controller, indicating that the receiver is now ready to receive data with the CDR in manual mode.

Figure 3-9: Reset Sequence Timing Diagram for Transceiver when CDR is in Manual Lock Mode



Resetting the Transceiver During Dynamic Reconfiguration

Reset is required for transceiver during dynamic reconfiguration except in the PMA Analog Control Reconfiguration mode.

In general, follow these guidelines when dynamically reconfiguring the transceiver:

1. Hold the targeted channel and PLL in the reset state before dynamic reconfiguration starts.
2. Repeat the sequence as needed after dynamic reconfiguration is complete, which is indicated by deassertion of the `reconfig_busy`, `tx_cal_busy`, `rx_cal_busy` signals.

Guidelines for Dynamic Reconfiguration if Transmitter Duty Cycle Distortion Calibration is Required During Device Operation

If transmitter duty cycle distortion calibration is required during device operation, ensure the general guidelines for transceiver dynamic reconfiguration are followed. Additionally, use the following recommendations:

1. Do not connect `tx_cal_busy` to the transceiver Reset Controller IP.
2. Disable the embedded reset controller and use an external reset controller.

Note: If channel reconfiguration is required before TX DCD calibration, ensure the following:

- The TX PLL, TX channel, and Transceiver Reconfiguration Controller blocks must not be in the reset state during TX DCD calibration. Ensure the following signals are not asserted during TX DCD calibration:
  - `pll_powerdown`
  - `tx_digitalreset`
  - `tx_analogreset`
  - `mgmt_rst_reset`

  Repeat the reset sequence when TX DCD calibration is complete.

  Arria V GZ devices do not require channel reconfiguration before TX dynamic reconfiguration calibration.

Note: Reset signals for the PMA are required only in PMA-direct mode.

Transceiver Blocks Affected by the Reset and Powerdown Signals

The following table lists blocks that are affected by specific reset and powerdown signals.

Table 3-7: Transceiver Blocks Affected

Transceiver Power-Down

To maximize power savings, enable PMA hard power-down across all channels on a side of the device where you do not use the transceivers.

The hard power-down granularity control of the transceiver PMA is per side (Arria V GX & Arria V GT) or per transceiver bank (Arria V GZ). To enable PMA hard power-down on the left or right side of the device, ground the transceiver power supply of the respective side.

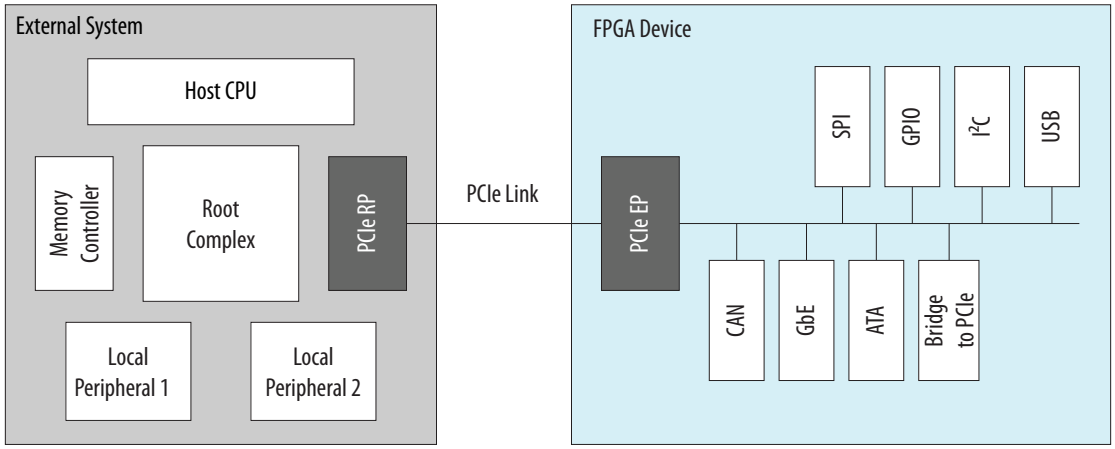
PCI Express

The Arria V devices have PCIe Hard IP that is designed for performance, ease-of-use, and increased functionality. The Hard IP consists of the media access control (MAC) lane, data link, and transaction layers. The PCIe Hard IP supports the PCIe Gen1 end point and root port up to x8 lane configurations. The PCIe endpoint support includes multifunction support for up to eight functions and Gen2 x4 lane configurations.

[33] The 9.8304 Gbps CPRI implementation (supported with 10-Gbps channels only) is implemented using PMA Direct mode. The PMA interfaces with the FPGA fabric directly, so you must implement the required PCS functionality in user logic (soft PCS).

Figure 4-1: PCIe Multifunction for Arria V Devices

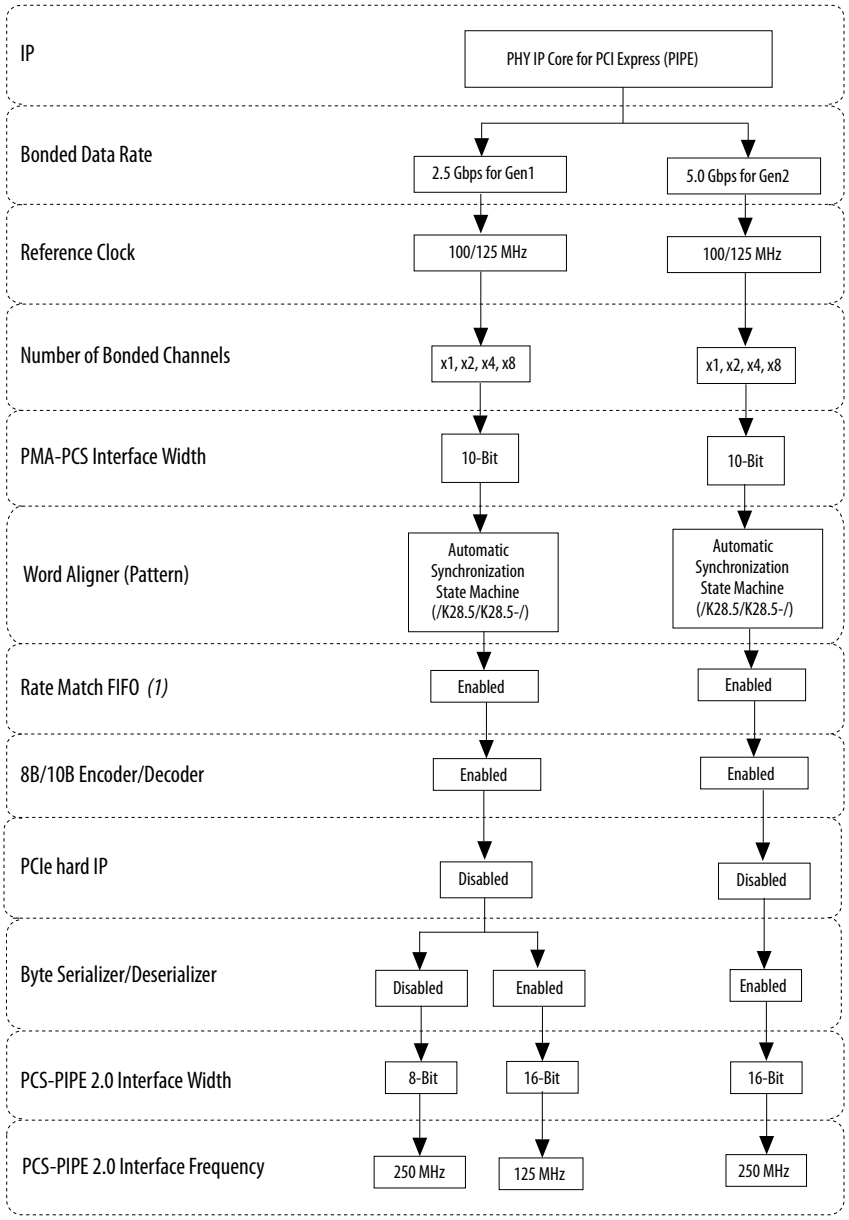


The Arria V PCIe Hard IP operates independently from the core logic, which allows the PCIe link to wake up and complete link training in less than 100 ms while the Arria V device completes loading the programming file for the rest of the device.

In addition, the Arria V device PCIe Hard IP has improved end-to-end datapath protection using error correction code (ECC).

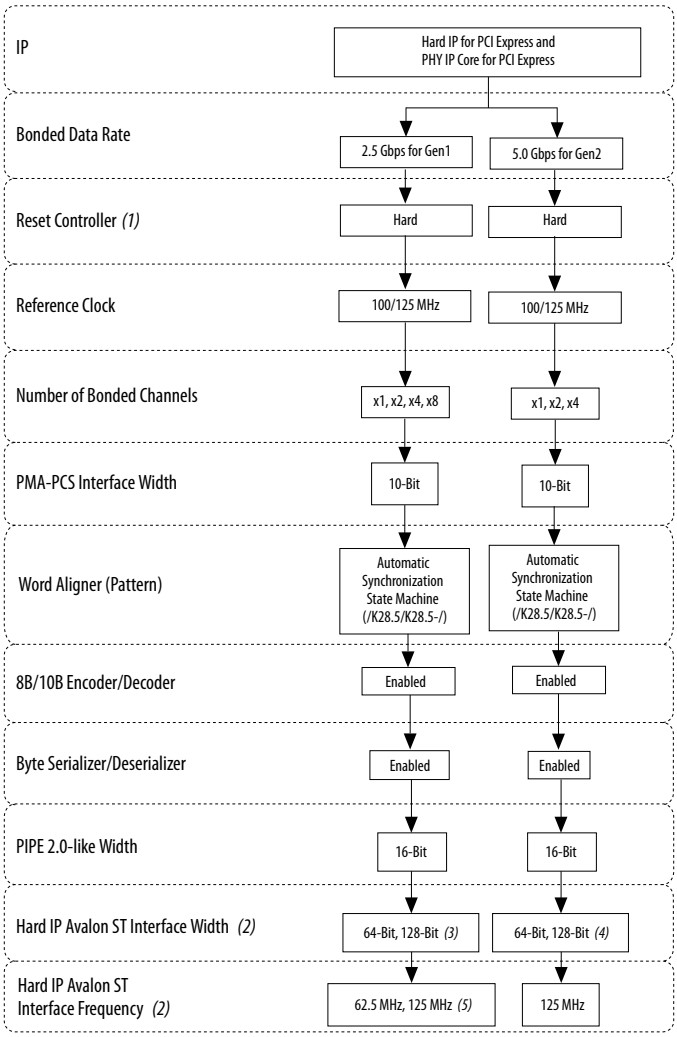
PCIe Transceiver Datapath

Figure 4-2: PCIe Gen1 and Gen2 PIPE Datapath Configuration



(1) When the PIPE low latency synchronous mode is enabled, the Rate Match FIFO operates in Low Latency mode.

Figure 4-3: PCIe Gen1 and Gen2 Hard IP and PHY IP Core for PCI Express Datapath Configuration

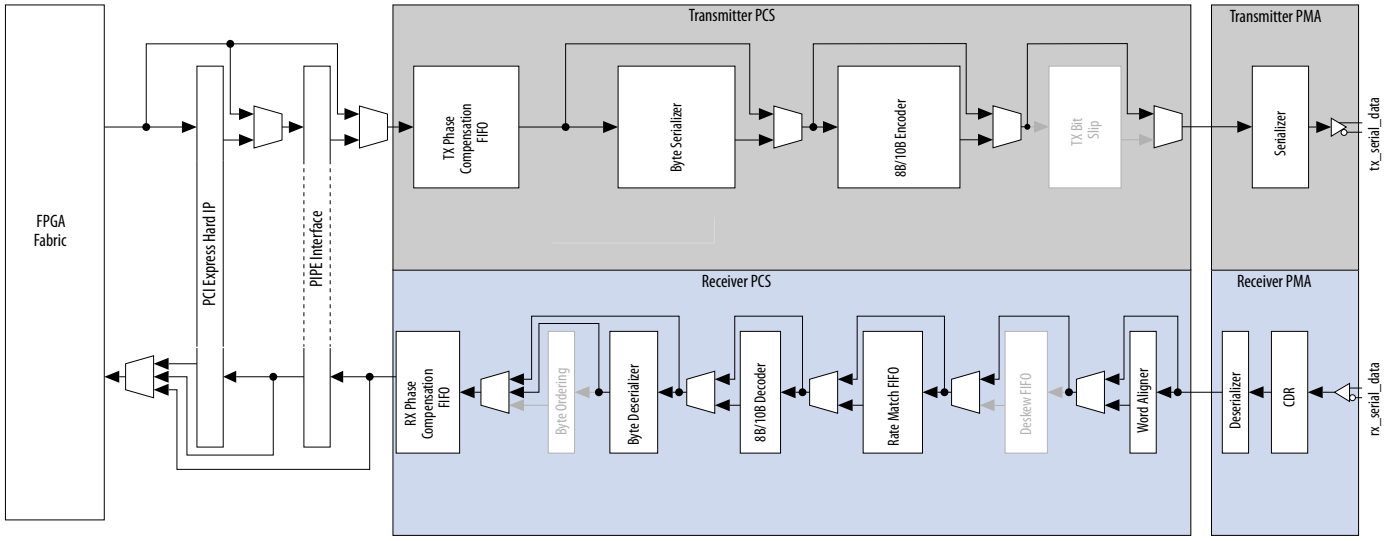


Notes:
(1) The PHY IP Core for PCI Express (PIPE configuration) employs the Embedded Reset Controller IP. It does not use the Hard or Soft Reset Controller employed in the Hard IP for PCI Express (HIP configuration).
(2) Does not apply to PHY IP Core for PCI Express configuration. Applies only to Hard IP for PCI Express configuration.
(3) 64-bit is for x1, x2, and x4 only. 128-bit is for x8 only.
(4) 64-bit is for x1 and x2 only. 128-bit is for x4 only.
(5) 62.5 MHz interface frequency is for x1 with 64-bit Hard IP Avalon ST Interface Width only.

The transceiver datapath clocking varies between non-bonded (x1) and bonded (x2, x4, and x8) configurations.

Transceiver Channel Datapath

Figure 4-4: Transceiver Channel Datapath in a PIPE Configuration



Related Information

Transceiver Architecture in Arria V Devices

PCIe Supported Features

The PIPE configuration for the 2.5 Gbps (Gen1) and 5 Gbps (Gen2) data rates supports these features:

- PCIe-compliant synchronization state machine
- ±300 parts per million (ppm)—total 600 ppm—clock rate compensation
- 8-bit FPGA fabric–transceiver interface
- 16-bit FPGA fabric–transceiver interface
- Transmitter buffer electrical idle
- Receiver detection
- 8B/10B encoder disparity control when transmitting compliance pattern
- Power state management (Electrical Idle only)
- Receiver status encoding

PIPE Interface

In a PIPE configuration, each channel has a PIPE interface block that transfers data, control, and status signals between the PHY-MAC layer and the transceiver channel PCS and PMA blocks.

The PIPE interface block complies with version 2.0 of the PIPE specification. If you use the PIPE hard IP block, the PHY-MAC layer is implemented in the hard IP block. Otherwise, you can implement the PHY-MAC layer using soft IP in the FPGA fabric.

If you use the PIPE hard IP block, the PHY-MAC layer is implemented in the hard IP block. Otherwise, you can implement the PHY-MAC layer using soft IP in the FPGA fabric, which will be supported in future versions of the Quartus II software.

Note: The PIPE interface block is used in a PIPE configuration and cannot be bypassed.

In addition to transferring data, control, and status signals between the PHY-MAC layer and the transceiver, the PIPE interface block implements the following functions that are required in a PCIe-compliant physical layer device:

- Forces the transmitter buffer into an electrical idle state
- Initiates the receiver detect sequence
- Controls the 8B/10B encoder disparity when transmitting a compliance pattern
- Manages the PCIe power states (Electrical Idle only)
- Indicates the completion of various PHY functions, such as receiver detection and power state transitions on the `pipe_phystatus` signal
- Encodes the receiver status and error conditions on the `pipe_rxstatus[2:0]` signal, as specified in the PCIe specification

Transmitter Electrical Idle Generation

The PIPE interface block places the channel transmitter buffer in an electrical idle state when the electrical idle input signal is asserted.

During electrical idle, the transmitter buffer differential and common configuration output voltage levels are compliant to the PCIe Base Specification 2.1 for the PCIe Gen2 data rate.

The PCIe specification requires that the transmitter buffer be placed in electrical idle in certain power states.

Power State Management

The PCIe specification defines four power states: P0, P0s, P1, and P2.

The physical layer device must support these power states to minimize power consumption:

- P0 is the normal operating state during which packet data is transferred on the PCIe link.
- P0s, P1, and P2 are low-power states into which the physical layer must transition as directed by the PHY-MAC layer to minimize power consumption.

The PIPE interface in the transceivers provides an input port for each transceiver channel configured in a PIPE configuration.

Note: When transitioning from the P0 power state to lower power states (P0s, P1, and P2), the PCIe specification requires that the physical layer device implements power saving measures. The transceivers do not implement these power saving measures except to place the transmitter buffer in electrical idle in the lower power states.

8B/10B Encoder Usage for Compliance Pattern Transmission Support

The PCIe transmitter transmits a compliance pattern when the Link Training and Status State Machine (LTSSM) enters a polling compliance substate. The polling compliance substate assesses if the transmitter is electrically compliant with the PCIe voltage and timing specifications.

Receiver Status

The PCIe specification requires that the PHY encode the receiver status on a 3-bit status signal (`pipe_rxstatus[2:0]`).

This status signal is used by the PHY-MAC layer for its operation. The PIPE interface block receives the status signals from the transceiver channel PCS and PMA blocks, and encodes the status on the

pipe_rxstatus[2:0] signal to the FPGA fabric. The encoding of the status signals on the pipe_rxstatus[2:0] signal is compliant with the PCIe specification.

Receiver Detection

The PIPE interface block in Arria V transceivers provides an input signal (pipe_txdetectrx_loopback) for the receiver detect operation that is required by the PCIe protocol during the detect substate of the LTSSM.

When the pipe_txdetectrx_loopback signal is asserted in the P1 power state, the PCIe interface block sends a command signal to the transmitter buffer in that channel to initiate a receiver detect sequence. In the P1 power state, the transmitter buffer must always be in the electrical idle state.

After receiving this command signal, the receiver detect circuitry creates a step voltage at the output of the transmitter buffer. If an active receiver that complies with the PCIe input impedance requirements is present at the far end, the time constant of the step voltage on the trace is higher than if the receiver is not present. The receiver detect circuitry monitors the time constant of the step signal that is seen on the trace to determine if a receiver was detected. The receiver detect circuitry monitor requires a 125-MHz clock for operation that you must drive on the fixedclk port.

Note: For the receiver detect circuitry to function reliably, the AC-coupling capacitor on the serial link and the receiver termination values used in your system must be compliant with the PCIe Base Specification 2.1.

The PCI Express PHY (PIPE) IP core provides a 1-bit PHY status (pipe_phystatus) and a 3-bit receiver status signal (pipe_rxstatus[2:0]) to indicate whether a receiver was detected or not, in accordance to the PIPE 2.0 specifications.

Clock Rate Compensation Up to ±300 ppm

In compliance with the PCIe protocol, the receiver channels are equipped with a rate match FIFO to compensate for the small clock frequency differences of up to ± 300 ppm between the upstream transmitter and local receiver clocks.

Related Information

Transceiver Architecture in Arria V Devices

PCIe Reverse Parallel Loopback

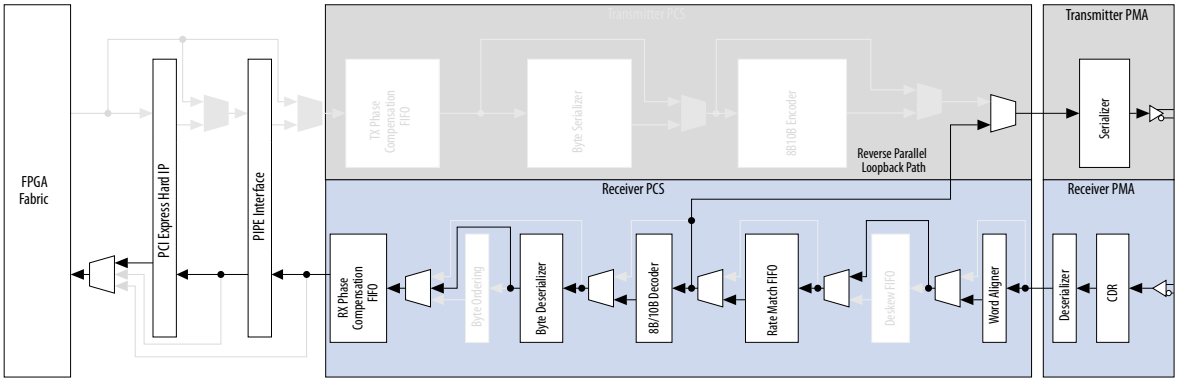
The PCIe reverse parallel loopback is only available in the PCIe functional configuration for the Gen1 data rate. The received serial data passes through the receiver CDR, deserializer, word aligner, and rate matching FIFO buffer. It is then looped back to the transmitter serializer and transmitted out through the transmitter buffer. The received data is also available to the FPGA fabric through the port.

This loopback mode is compliant with the PCIe specification 2.1.

Arria V devices provide the pipe_txdetectrx_loopback input signal to enable this loopback mode. If the pipe_txdetectrx_loopback signal is asserted in the P1 power state, receiver detection is performed. If the signal is asserted in the P0 power state, reverse parallel loopback is performed.

Note: The PCIe reverse parallel loopback is the only loopback option that is supported in PIPE configurations.

Figure 4-5: PIPE Reverse Parallel Loopback Mode Datapath



PIPE Transceiver Channel Placement Guidelines

Table 4-2: PIPE Channel Placement for PCIe Gen1

Placement by the Quartus II software may vary with design, resulting in higher channel utilization.

Configuration	Data Channel Placement	Minimum Channel Utilization	Default Logical Data Channel Number for Master
x1	Any channel	2 (1 data channel, 1 clock channel)	Data_channel[0]
x2	2 contiguous channels	3 (2 data channels, 1 clock channel)	Data_channel[1]
x4	4 contiguous channels	5 (4 data channels, 1 clock channel)	Data_channel[1]
x8	8 contiguous channels	9 (8 data channels, 1 clock channel)	Data_channel[0]

To override the default data channel number for the Master channel, do following:

1. Assign the Master channel to the same bank of CMU PLL.
2. Apply the following Quartus II QSF assignment:

```
set_parameter -name master_ch_number <logical_data_channel_number>
-to <"test:pcie_i|altera_xcvr_pipe:test_inst|av_xcvr_pipe_nr:pipe_nr_inst|
av_xcvr_pipe_native:transceiver_core">
```

To support PIPE placement identical to PCIe HIP x8, use following two Quartus II QSF assignments:

```
set_parameter -name master_ch_number 4 -to <"test:pcie_i|altera_xcvr_pipe:test_inst|
av_xcvr_pipe_nr:pipe_nr_inst|
av_xcvr_pipe_native:transceiver_core”>

set_parameter -name dummy_ch_required 1 -to <"test:pcie_i|
altera_xcvr_pipe:test_inst|av_xcvr_pipe_nr:pipe_nr_inst|
av_xcvr_pipe_native:transceiver_core">
```

Note: For more information about the hard IP implementation of PCIe and restrictions, refer to the “Transceiver Banks” section of the *Transceiver Architecture in Arria V Devices* chapter.

The following four figures show examples of channel placement for PIPE x1, x2, x4, and x8 configurations.

Figure 4-6: Example of PIPE x1 Channel Placement

Channels shaded in blue provide the high-speed serial clock. Channels shaded in gray are data channels. You can place the PIPE data channels in any available channel in the transceiver bank.

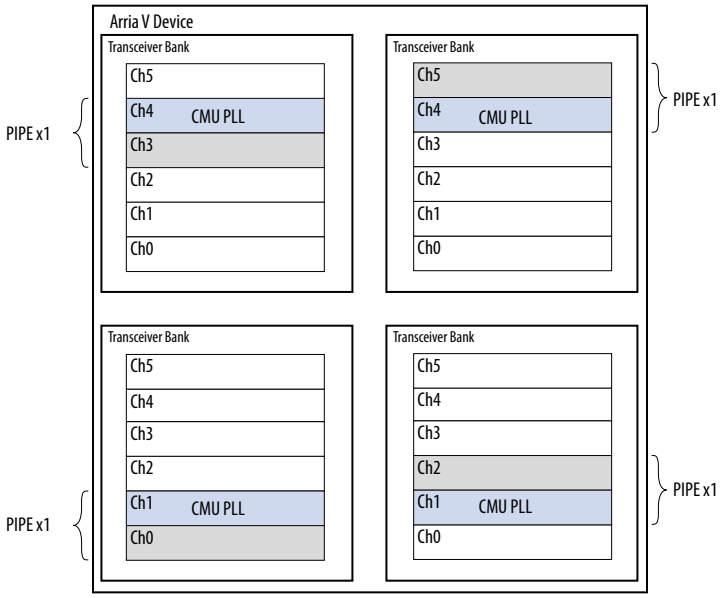


Figure 4-7: Example of PIPE x2 Channel Placement

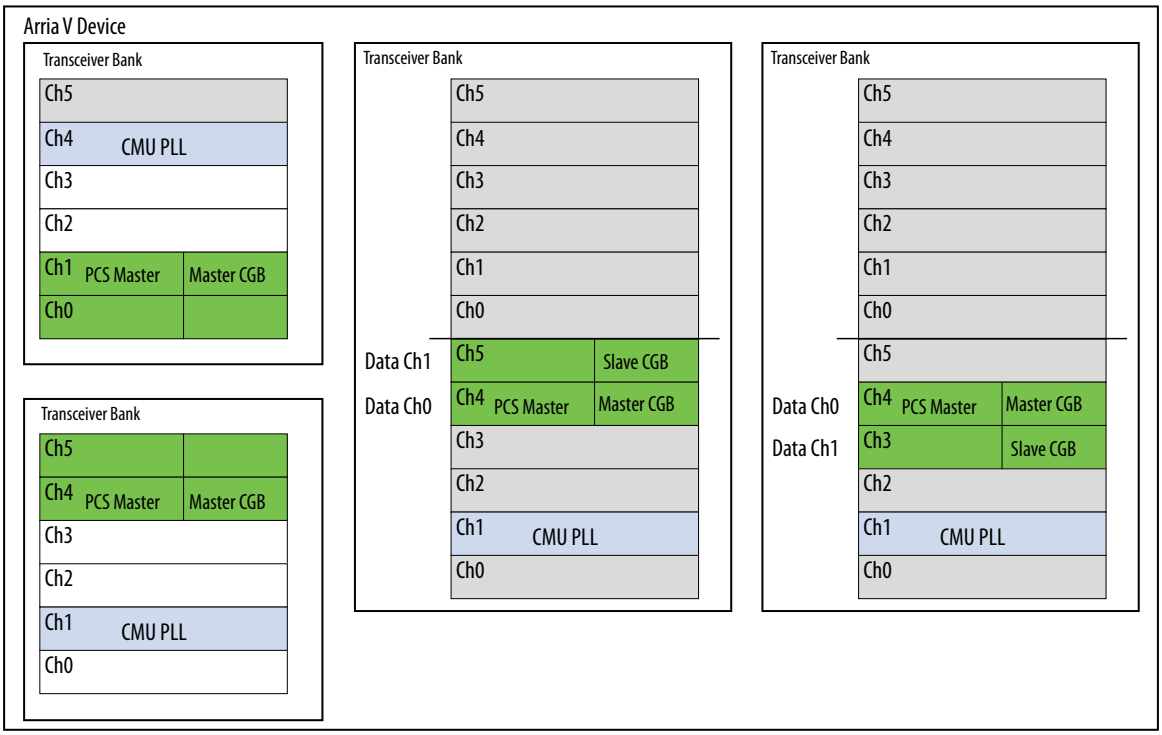

Figure 4-8: Example of PIPE x4 Channel Placement

Channels shaded in blue provide the high-speed serial clock. Channels shaded in gray are data channels.

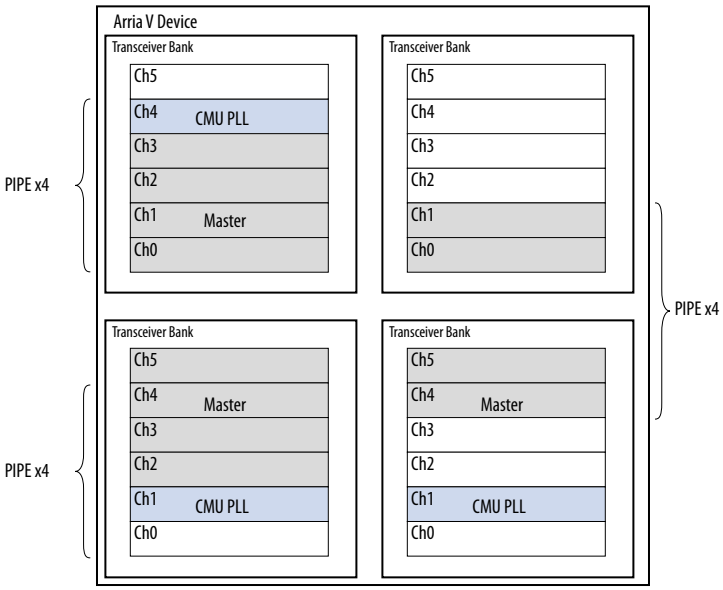

Figure 4-9: Example of PIPE x8 Channel Placement

Channels shaded in blue provide the high-speed serial clock. Channels shaded in gray are data channels.

Transceiver Architecture in Arria V Devices

PCIe Supported Configurations and Placement Guidelines

Placement by the Quartus II software may vary with design and device. The following figures show examples of transceiver channel and PCIe Hard IP block locations, supported x1, x2, x4, and x8 bonding configurations, and channel placement guidelines. The Quartus II software automatically places the CMU PLL in a channel different from that of the data channels.

Note: This section shows the supported PCIe channel placement if you use both the top and bottom PCIe Hard IP blocks in the device separately.

The following guidelines apply to all channel placements:

- The CMU PLL requires its own channel and must be placed on channel 1 or channel 4
- The PCIe channels must be contiguous within the transceiver bank
- Lane 0 of the PCIe must be placed on channel 0 or channel 5

In the following figures, channels shaded in blue provide the high-speed serial clock. Channels shaded in gray are data channels.

Figure 4-10: PCIe HIP Supported x1 Guidelines

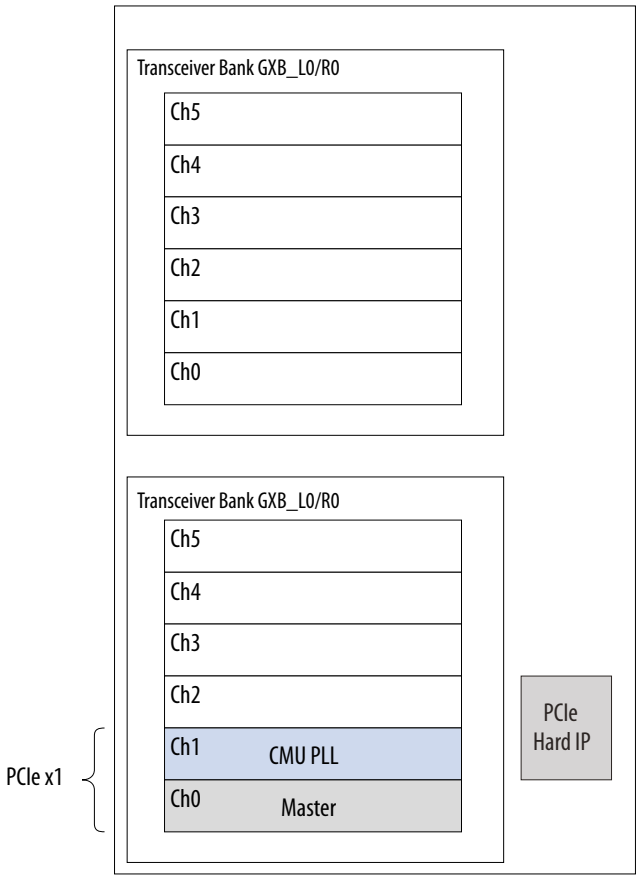

Figure 4-11: PCIe HIP Supported x2 and x4 Guidelines

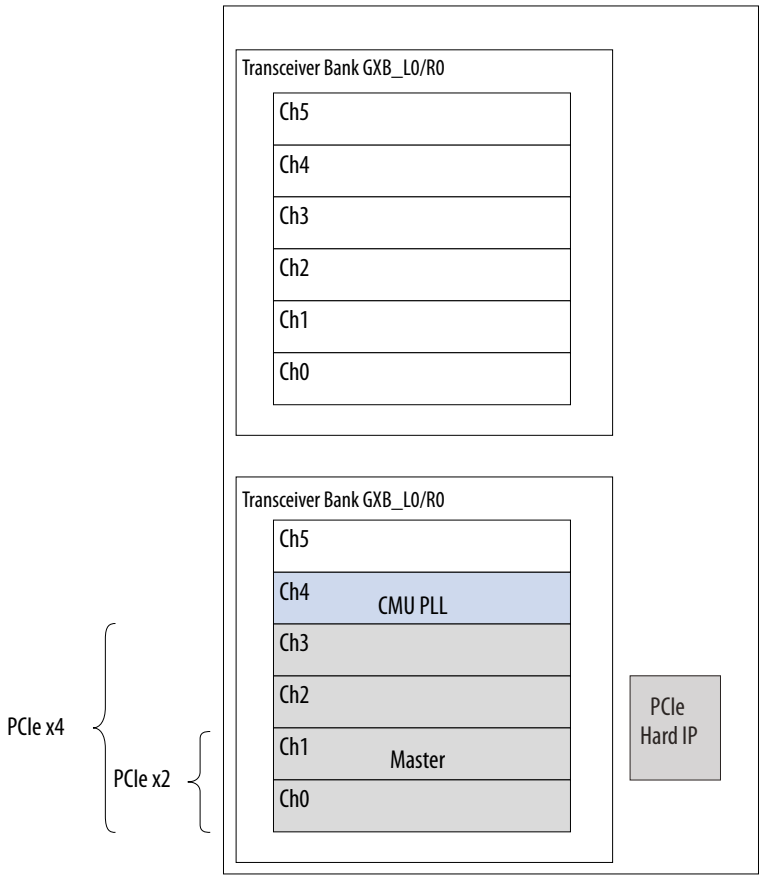

Figure 4-12: PCIe HIP Supported x8 Guidelines

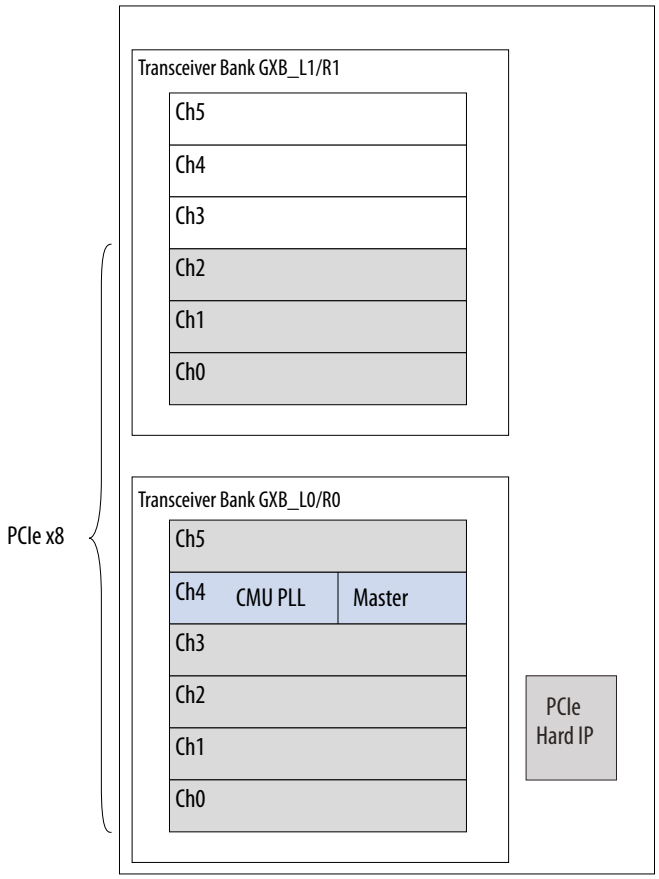

For PCIe Gen1 and Gen2, there are restrictions on the achievable x1 and x4 bonding configurations if you intend to use both top and bottom Hard IP blocks in the device.

Transceiver Architecture in Arria V Devices

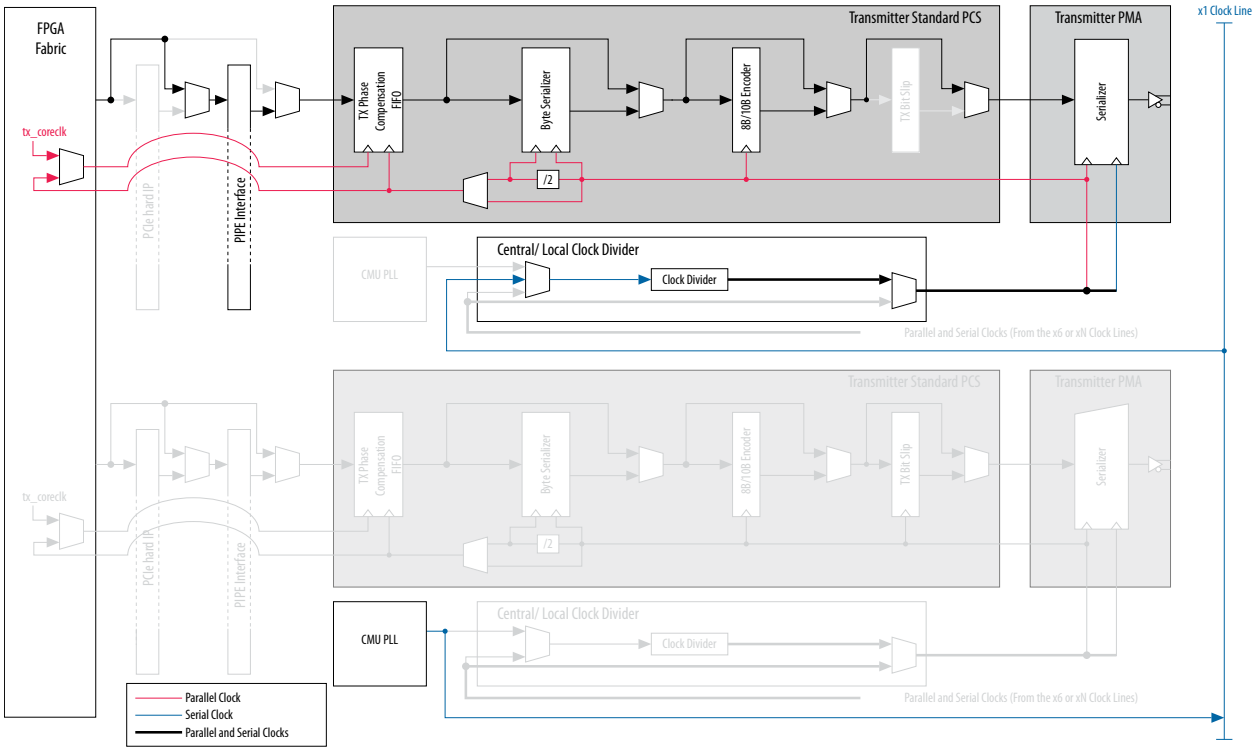
PIPE Transceiver Clocking

This section describes transceiver clocking for PIPE configurations.

PIPE x1 Configuration

The serial clock in the transceiver clocking configuration is provided by the CMU PLL in a channel different from that of the data channel. The local clock divider block in the data channel generates a parallel clock from this high-speed clock and distributes both clocks to the PMA and PCS of the data channel.

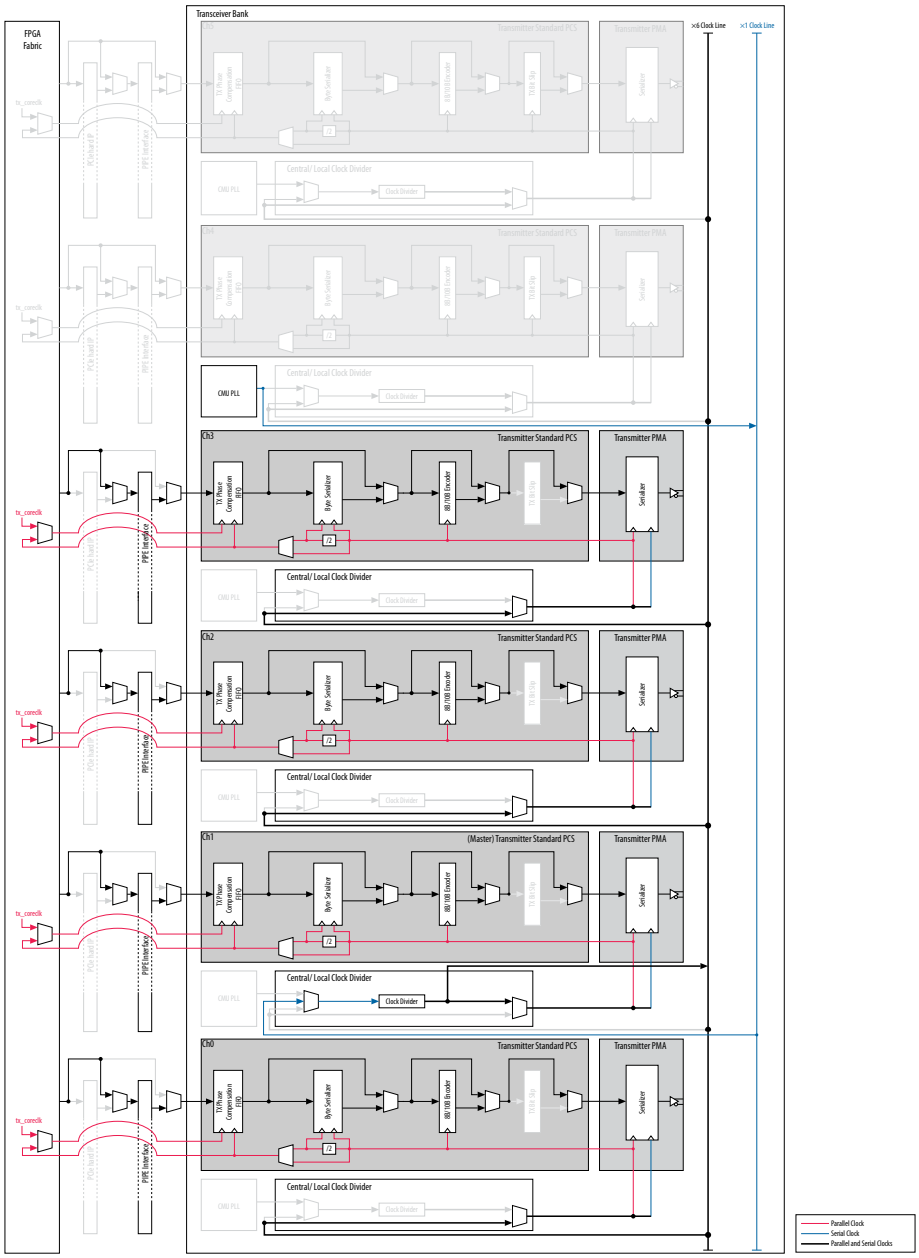
Figure 4-13: Transceiver Clocking Configuration in a PIPE x1 Configuration



PIPE x4 Configuration

In a PIPE x4 bonded configuration, clocking is independent for the receiver channels. The clocking and control signals are bonded only for the transmitter channels.

Figure 4-14: Transceiver Clocking Configuration in a PIPE x4 Configuration



PIPE x8 Configuration

In a PIPE x8 bonded configuration, the clocking for the PMA and PCS blocks is independent for the receiver channels. The clocking and control signals are bonded only for the transmitter channels.

For more information about clocking in Arria V devices, refer to the *Transceiver Clocking in Arria V Devices* chapter.

Figure 4-15: Transceiver Clocking Configuration in a PIPE x8 Configuration

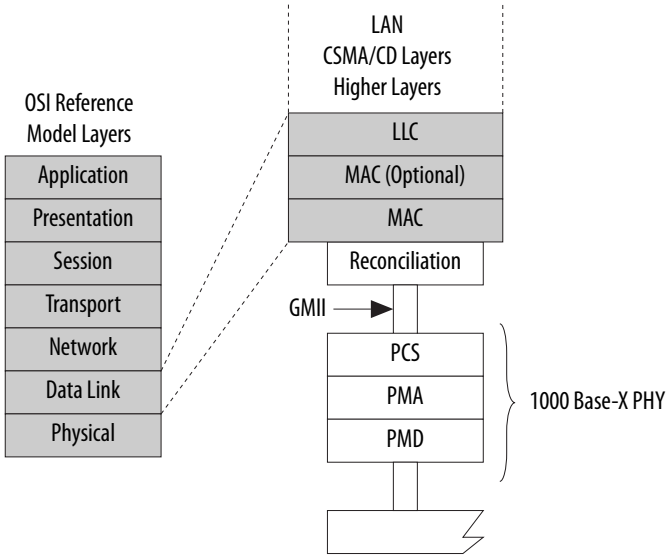
Gigabit Ethernet

The IEEE 802.3 specification defines the 1000BASE-X PHY as an intermediate, or transition layer that interfaces various physical media with the MAC in a gigabit ethernet (GbE) system, shielding the MAC

layer from the specific nature of the underlying medium. The 1000BASE-X PHY is divided into the PCS, PMA, and PMD sublayers.

The PCS sublayer interfaces with the MAC through the gigabit media independent interface (GMII). The 1000BASE-X PHY defines a physical interface data rate of 1 Gbps and 2.5 Gbps.

Figure 4-16: 1000BASE-X PHY in a GbE OSI Reference Model



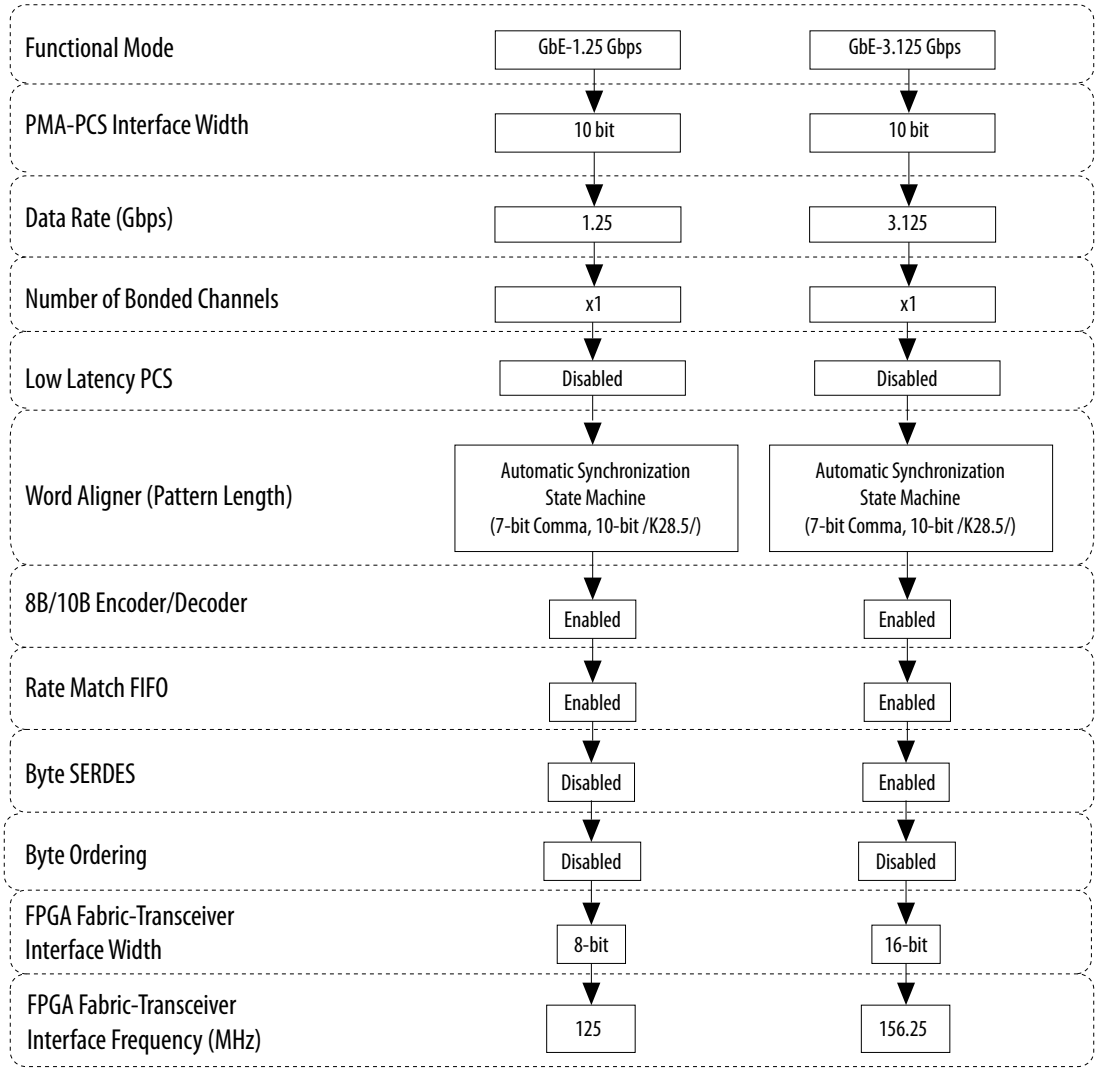
The transceivers, when configured in GbE functional mode, have built-in circuitry to support the following PCS and PMA functions, as defined in the IEEE 802.3 specification:

- 8B/10B encoding and decoding
- Synchronization
- Clock recovery from the encoded data forwarded by the receiver PMD
- Serialization and deserialization

Note: If you enabled the autonegotiation state machine in the FPGA core with the rate match FIFO, refer to the "Rate Match FIFO" section in the "Gigabit Ethernet Transceiver Datapath" section.

Note: The transceivers do not have built-in support for other PCS functions, such as the autonegotiation state machine, collision-detect, and carrier-sense functions. If you require these functions, implement them in the FPGA fabric or in external circuits.

Figure 4-17: Transceiver Blocks in a GbE Configuration



Related Information

Gigabit Ethernet Transceiver Datapath

Figure 4-18: Transceiver Datapath in GbE-1.25 Gbps Configuration

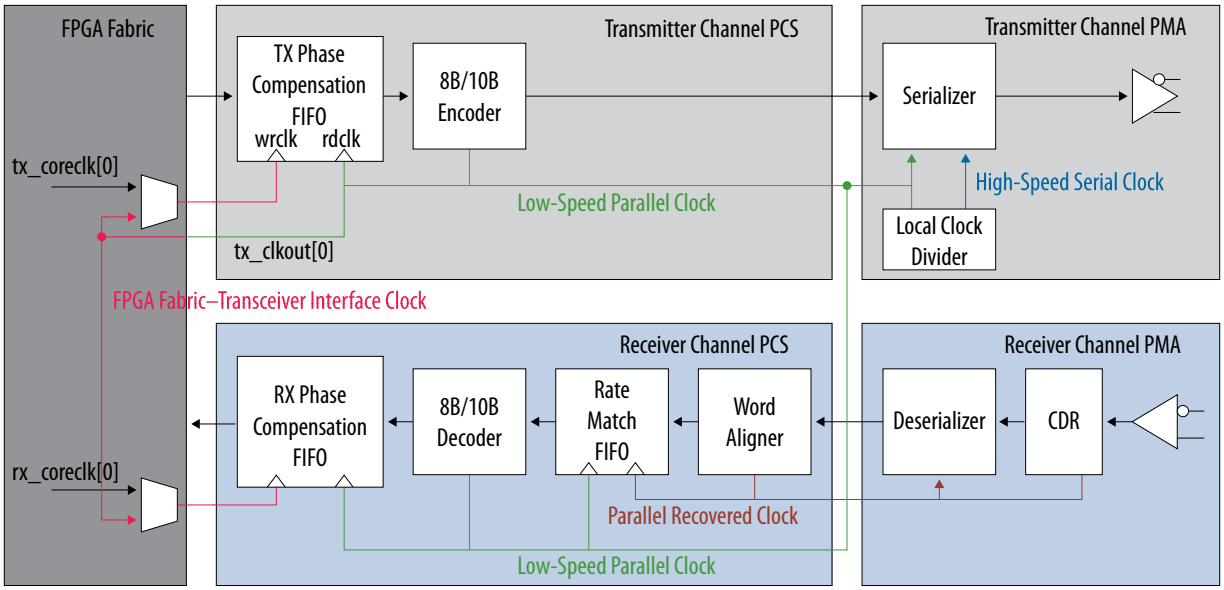

Figure 4-19: Transceiver Datapath in GbE-3.125 Gbps Configuration

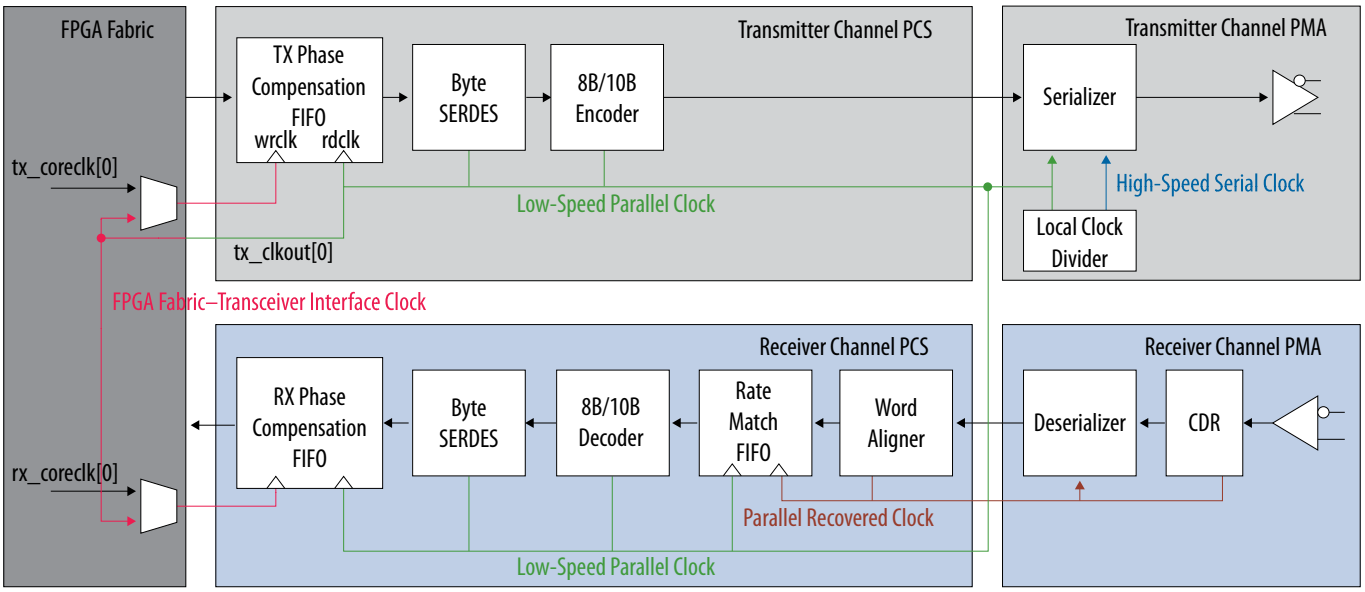

Table 4-3: Transceiver Datapath Clock Frequencies in GbE Configuration

Functional Mode	Data Rate	High-Speed Serial Clock Frequency	Parallel Recovered Clock and Low-Speed Parallel Clock Frequency	FPGA Fabric-Transceiver Interface Clock Frequency
GbE-1.25 Gbps	1.25 Gbps	625 MHz	125 MHz	125 MHz
GbE-3.125 Gbps	3.125 Gbps	1562.5 MHz	312.5 MHz	156.25 MHz

8B/10B Encoder

In GbE configuration, the 8B/10B encoder clocks in 8-bit data and 1-bit control identifiers from the transmitter phase compensation FIFO and generates 10-bit encoded data. The 10-bit encoded data is fed to the serializer.

For more information about the 8B/10B encoder functionality, refer to the **Transceiver Architecture for Arria V Devices** chapter.

Rate Match FIFO

In GbE configuration, the rate match FIFO is capable of compensating for up to ±100 ppm (200 ppm total) difference between the upstream transmitter and the local receiver reference clock. The GbE protocol requires that the transmitter send idle ordered sets /I1/ (/K28.5/D5.6/) and /I2/ (/K28.5/D16.2/) during interpacket gaps, adhering to the rules listed in the IEEE 802.3 specification.

The rate match operation begins after the synchronization state machine in the word aligner indicates that the synchronization is acquired-by driving the `rx_syncstatus` signal high. The rate matcher always deletes or inserts both symbols (/K28.5/ and /D16.2/) of the /I2/ ordered sets, even if only one symbol needs to be deleted to prevent the rate match FIFO from overflowing or underrunning. The rate matcher can insert or delete as many /I2/ ordered sets as necessary to perform the rate match operation.

Two flags are forwarded to the FPGA fabric:

- `rx_rmfifodatadeleted`—Asserted for two clock cycles for each deleted /I2/ ordered set to indicate the rate match FIFO deletion event
- `rx_rmfifodatainserted`—Asserted for two clock cycles for each inserted /I2/ ordered set to indicate the rate match FIFO insertion event

Note: If you have the autonegotiation state machine in the FPGA, note that the rate match FIFO is capable of inserting or deleting the first two bytes (/K28.5//D2.2/) of /C2/ ordered sets during autonegotiation. However, the insertion or deletion of the first two bytes of /C2/ ordered sets can cause the autonegotiation link to fail. For more information, refer to the **Altera Knowledge Base Support Solution**.

For more information about the rate match FIFO, refer to the **Transceiver Architecture for Arria V Devices** chapter.

GbE Protocol-Ordered Sets and Special Code Groups

Table 4-4: GIGE Ordered Sets

The following ordered sets and special code groups are specified in the IEEE 802.3-2008 specification.

Code	Ordered Set	Number of Code Groups	Encoding
/C/	**Configuration**	—	Alternating /C1/ and /C2/
/C1/	Configuration 1	4	/K28.5/D21.5/ `Config_Reg` (34)
/C2/	Configuration 2	4	/K28.5/D2.2/ `Config_Reg` (34)
/I/	**IDLE**	—	Correcting /I1/, Preserving /I2/
/I1/	IDLE 1	2	/K28.5/D5.6/
/I2/	IDLE 2	2	/K28.5/D16.2/
-	**Encapsulation**	—	—
/R/	`Carrier_Extend`	1	/K23.7/
/S/	`Start_of_Packet`	1	/K27.7/
/T/	`End_of_Packet`	1	/K29.7/
/V/	`Error_Propagation`	1	/K30.7/

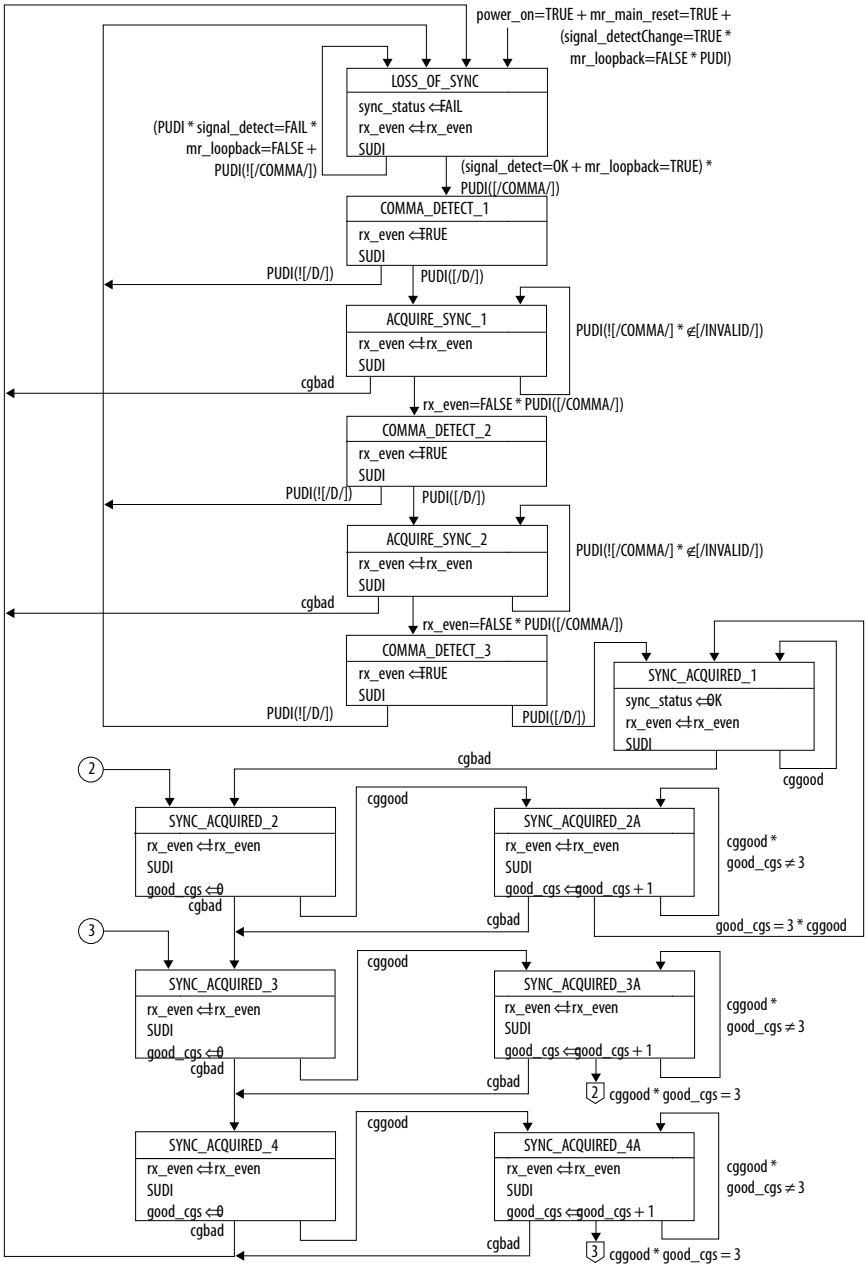
Table 4-5: Synchronization State Machine Parameters in GbE Mode

Synchronization State Machine Parameters	Setting
Number of valid {/K28.5/, /Dx,y/} ordered sets received to achieve synchronization	3
Number of errors received to lose synchronization	4
Number of continuous good code groups received to reduce the error count by 1	4

(34) Two data code groups represent the `Config_Reg` value.

Figure 4-20: Synchronization State Machine in GbE Mode

This figure is from "Figure 36–9" in the IEEE 802.3-2008 specification. For more details about the 1000BASE-X implementation, refer to Clause 36 of the IEEE 802.3-2008 specification.



Related Information

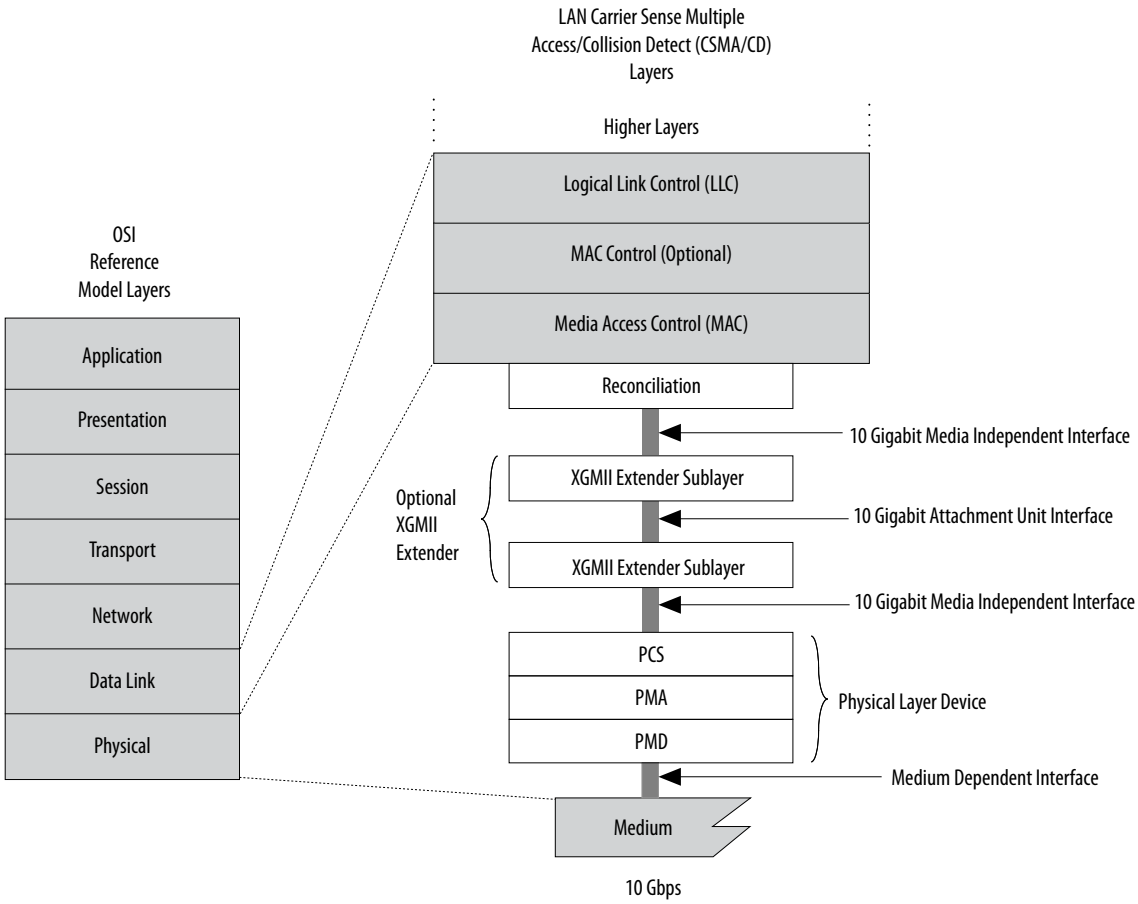
Refer to the "Custom PHY IP Core" and "Native PHY IP Core" chapters in the Altera Transceiver PHY IP Core User Guide

XAUI

In a XAUI configuration, the transceiver channel data path is configured using soft PCS. It provides the transceiver channel datapath description, clocking, and channel placement guidelines. To implement a XAUI link, instantiate the XAUI PHY IP core in the IP Catalog, which is under Ethernet in the Interfaces menu. The XAUI PHY IP core implements the XAUI PCS in soft logic.

XAUI is a specific physical layer implementation of the 10 Gigabit Ethernet link defined in the IEEE 802.3ae-2002 specification. The XAUI PHY uses the XGMII interface to connect to the IEEE802.3 MAC and Reconciliation Sublayer (RS). The IEEE 802.3ae-2002 specification requires the XAUI PHY link to support a 10 Gbps data rate at the XGMII interface and four lanes each at 3.125 Gbps at the PMD interface.

Figure 4-21: XAUI and XGMII Layers



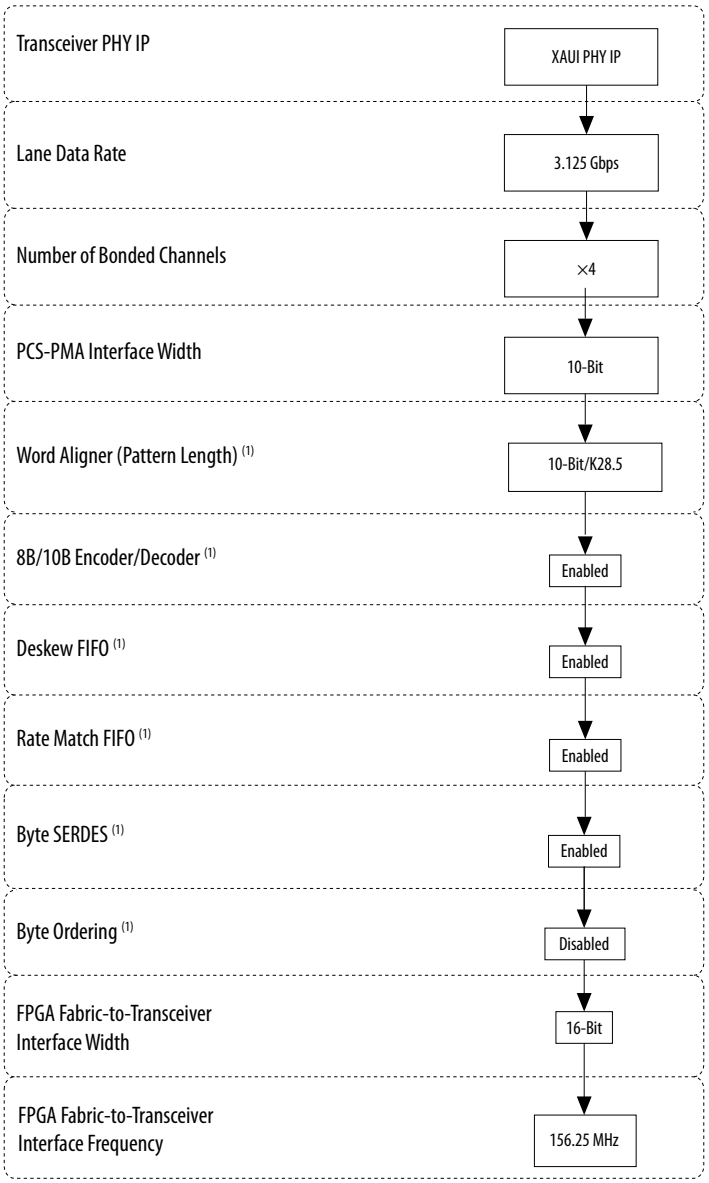
Related Information

Refer to the "XAUI PHY IP Core" chapter in the Altera Transceiver PHY IP Core User Guide.

Transceiver Datapath in a XAUI Configuration

The XAUI PCS is implemented in soft logic inside the FPGA core when using the XAUI PHY IP core. You must ensure that your channel placement is compatible with the soft PCS implementation.

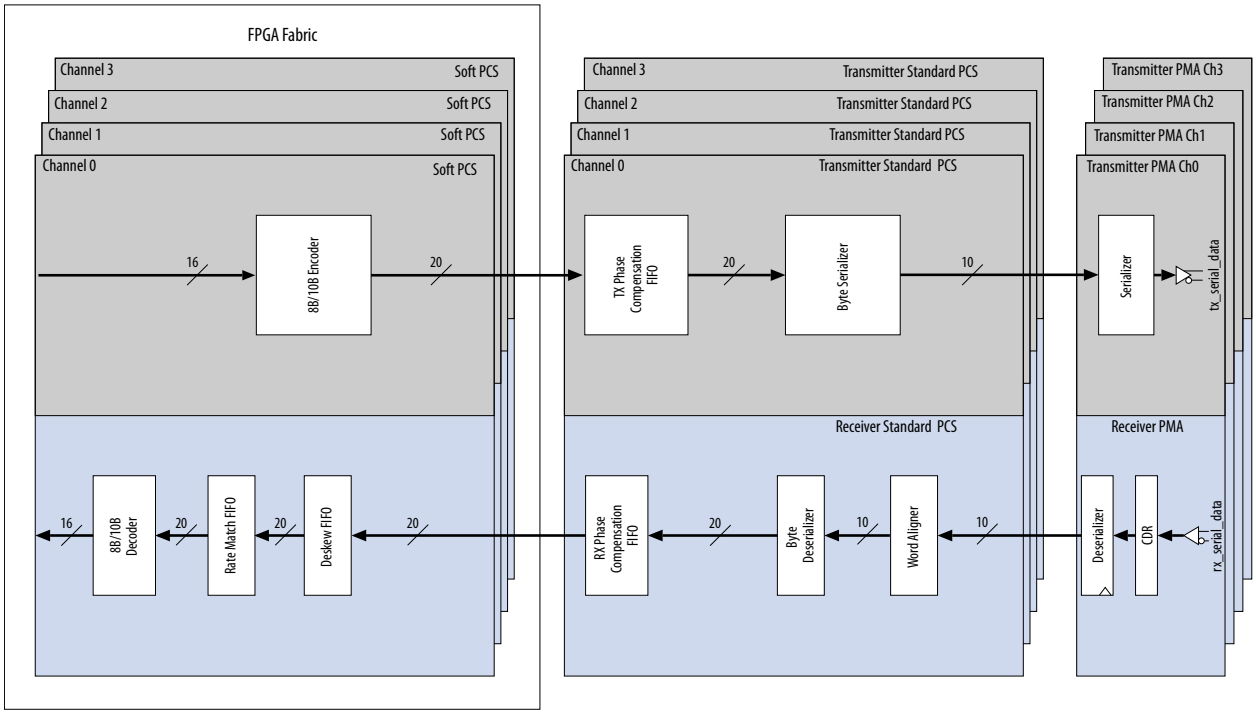
Figure 4-22: XAUI Configuration Datapath



Note:
1. Implemented in soft logic.

Figure 4-23: Transceiver Channel Datapath for XAUI Configuration

Standard PCS in a low latency configuration is used in this configuration. Additionally, a portion of the PCS is implemented in soft logic.



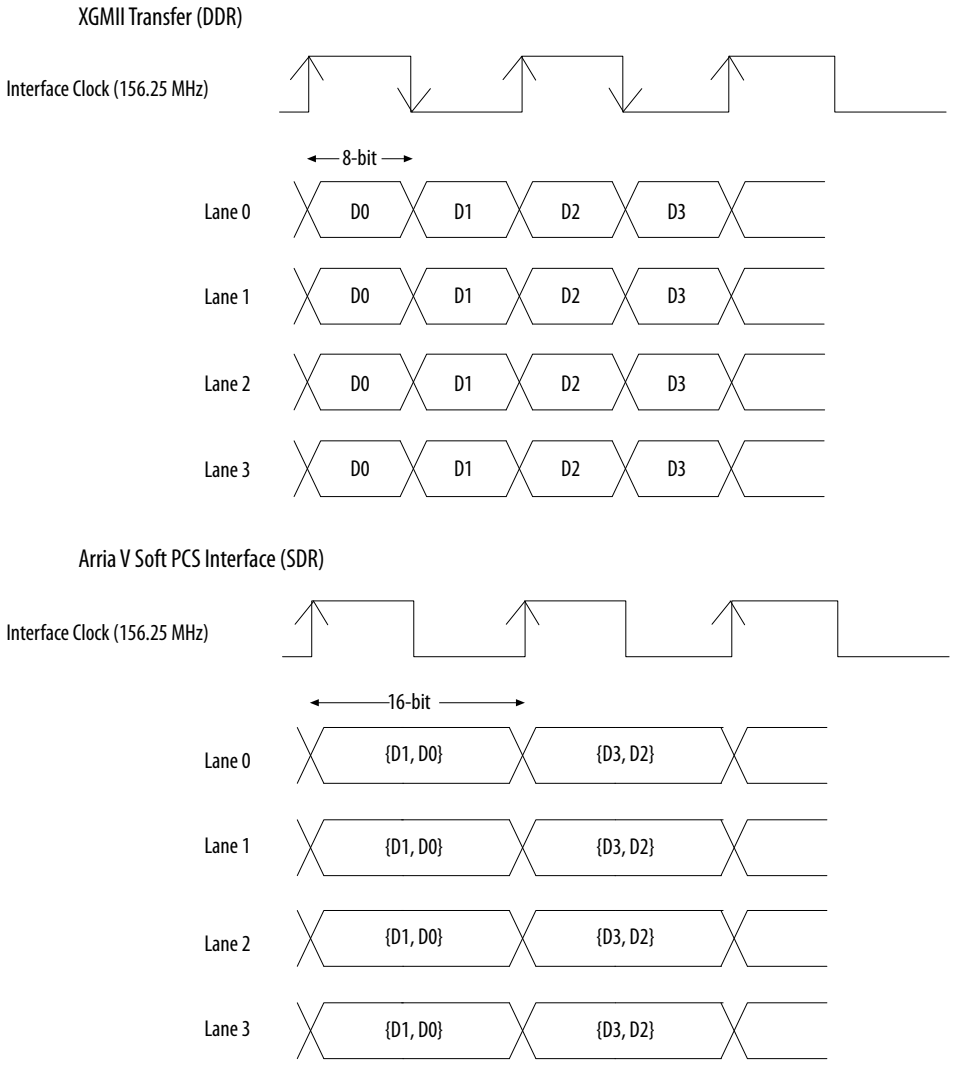
XAUI Supported Features

64-Bit SDR Interface to the MAC/RS

Clause 46 of the IEEE 802.3-2008 specification defines the XGMII interface between the XAUI PCS and the Ethernet MAC/RS. The specification requires each of the four XAUI lanes to transfer 8-bit data and 1-bit wide control code at both the positive and negative edge (DDR) of the 156.25 MHz interface clock.

Arria V transceivers and soft PCS solution in a XAUI configuration do not support the XGMII interface to the MAC/RS as defined in IEEE 802.3-2008 specification. Instead, they allow the transferring of 16-bit data and 2-bit control code on each of the four XAUI lanes, only at the positive edge (SDR) of the 156.25 MHz interface clock

Figure 4-24: Implementation of the XGMII Specification in Arria V Devices Configuration



8B/10B Encoding/Decoding

Each of the four lanes in a XAUI configuration support an independent 8B/10B encoder/decoder as specified in Clause 48 of the IEEE802.3-2008 specification. 8B/10B encoding limits the maximum number of consecutive 1s and 0s in the serial data stream to five, thereby ensuring DC balance as well as enough transitions for the receiver CDR to maintain a lock to the incoming data.

The XAUI PHY IP core provides status signals to indicate running disparity as well as the 8B/10B code group error.

Transmitter and Receiver State Machines

In a XAUI configuration, the Arria V soft PCS implements the transmitter and receiver state diagrams shown in Figure 48-6 and Figure 48-9 of the IEEE802.3-2008 specification.

In addition to encoding the XGMII data to PCS code groups, in conformance with the 10GBASE-X PCS, the transmitter state diagram performs functions such as converting Idle ||I|| ordered sets into Sync ||K||, Align ||A||, and Skip ||R|| ordered sets.

In addition to decoding the PCS code groups to XGMII data, in conformance with the 10GBASE-X PCS, the receiver state diagram performs functions such as converting Sync ||K||, Align ||A||, and Skip ||R|| ordered sets to Idle ||I|| ordered sets.

Synchronization

The word aligner block in the receiver PCS of each of the four XAUI lanes implements the receiver synchronization state diagram shown in Figure 48-7 of the IEEE802.3-2008 specification.

The XAUI PHY IP core provides a status signal per lane to indicate if the word aligner is synchronized to a valid word boundary.

Deskew

The lane aligner block in the receiver PCS implements the receiver deskew state diagram shown in Figure 48-8 of the IEEE 802.3-2008 specification.

The lane aligner starts the deskew process only after the word aligner block in each of the four XAUI lanes indicates successful synchronization to a valid word boundary.

The XAUI PHY IP core provides a status signal to indicate successful lane deskew in the receiver PCS.

Clock Compensation

The rate match FIFO in the receiver PCS datapath compensates up to ±100 ppm difference between the remote transmitter and the local receiver. It does so by inserting and deleting Skip ||R|| columns, depending on the ppm difference.

The clock compensation operation begins after:

- The word aligner in all four XAUI lanes indicates successful synchronization to a valid word boundary.
- The lane aligner indicates a successful lane deskew.

The rate match FIFO provides status signals to indicate the insertion and deletion of the Skip ||R|| column for clock rate compensation.

Transceiver Clocking and Channel Placement Guidelines in XAUI Configuration

Transceiver Clocking

Figure 4-25: Transceiver Clocking for XAUI Configuration

One of the two channel PLLs configured as a CMU PLL in a transceiver bank generates the transmitter serial and parallel clocks for the four XAUI channels. The x6 clock line carries the transmitter serial and parallel clocks to the PMA and PCS of each of the four channels.

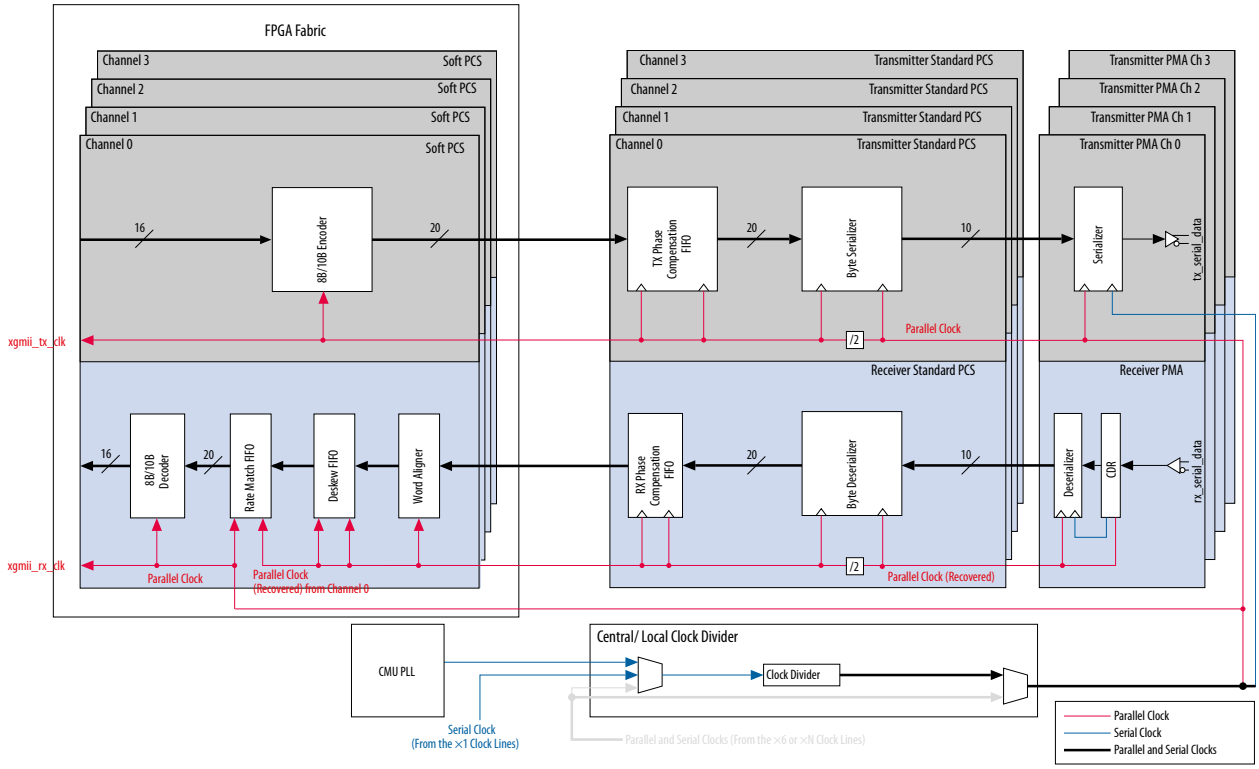


Table 4-6: Input Reference Clock Frequency and Interface Speed Specifications for XAUI Configurations

Input Reference Clock Frequency (MHz)	FPGA Fabric-Transceiver Interface Width	FPGA Fabric-Transceiver Interface Frequency (MHz)
156.25	16-bit data, 2-bit control	156.25

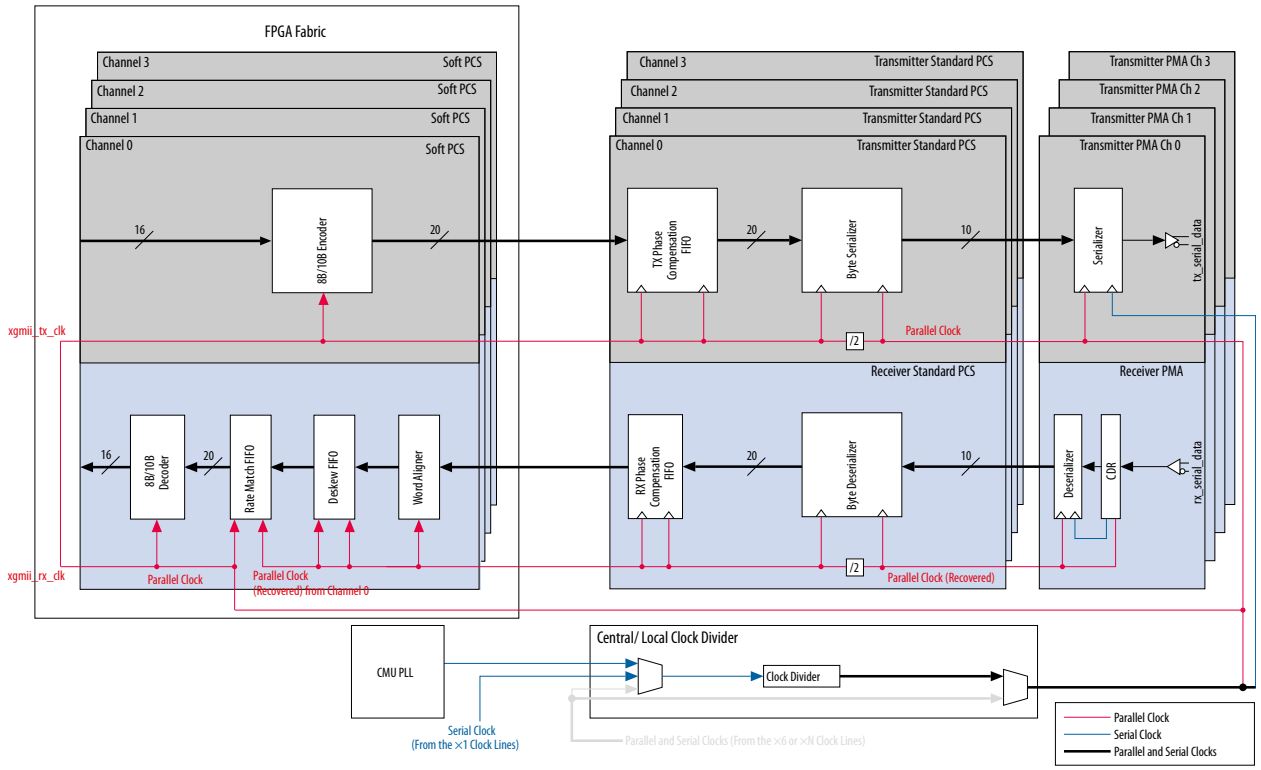
Transceiver Clocking Guidelines for Soft PCS Implementation

In the soft PCS implementation in the XAUI configuration, you must route `xgmii_rx_clk` to `xgmii_tx_clk` as shown in the following figure.

This method uses `xgmii_rx_clk` to compensate for the phase difference on the TX side.

Without this method, the `tx_digitalreset` signal may experience intermittent failure.

Figure 4-26: Transceiver Clocking for XAUI Soft PCS Implementation



Transceiver Channel Placement Guidelines

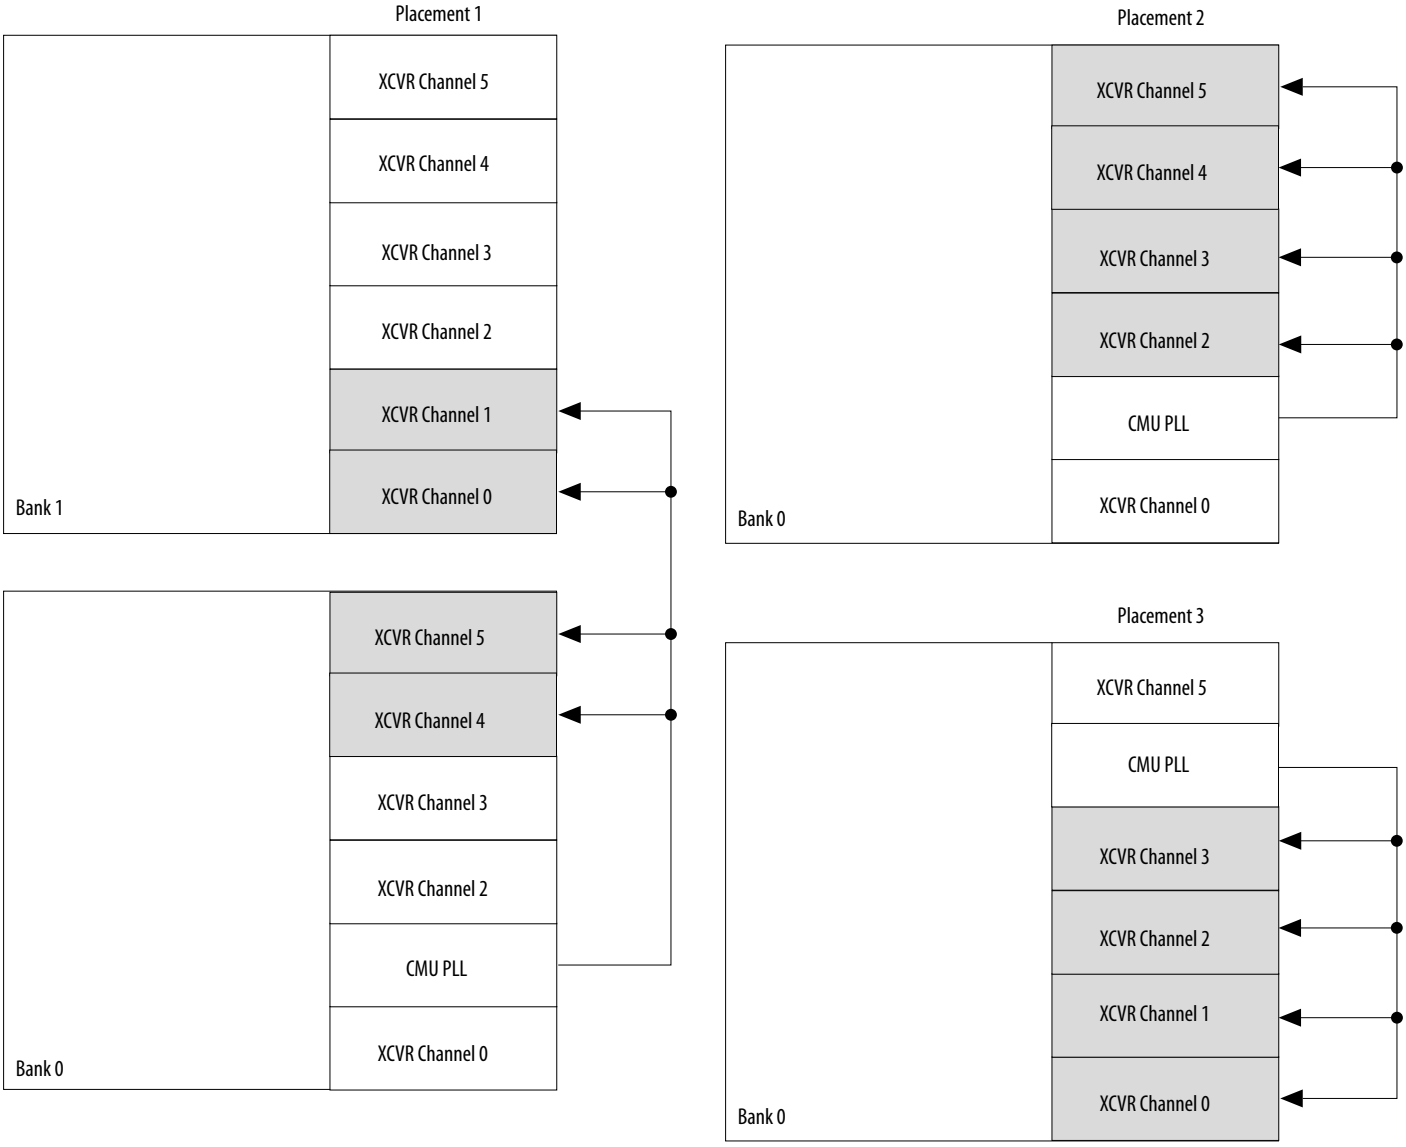
In the soft PCS implementation of the XAUI configuration, you can construct the four XAUI lanes at any channels within the two transceiver banks. However, Altera recommends you place the four channels contiguously to close timing more easily The channels may all be placed in one bank or they may span two banks. The following figure shows several possible channel placements when using the CMU PLL to drive the XAUI link.

The soft PCS implementation of the XAUI configuration has the following channel placement restrictions:

- The channels must be contiguous.
- Ch1 or Ch4 must be selected as logical channel 0.

Figure 4-27: Transceiver Channel Placement Guidelines in a XAUI Configuration

The Quartus II software implements the XAUI PCS in soft logic. Each XAUI link requires a dedicated CMU PLL. A single CMU PLL cannot be shared among different XAUI links.



Related Information

To implement the QSF assignment workaround using the Assignment Editor, refer to the "XAUI PHY IP Core" chapter in the Altera Transceiver PHY IP Core User Guide.

10GBASE-R

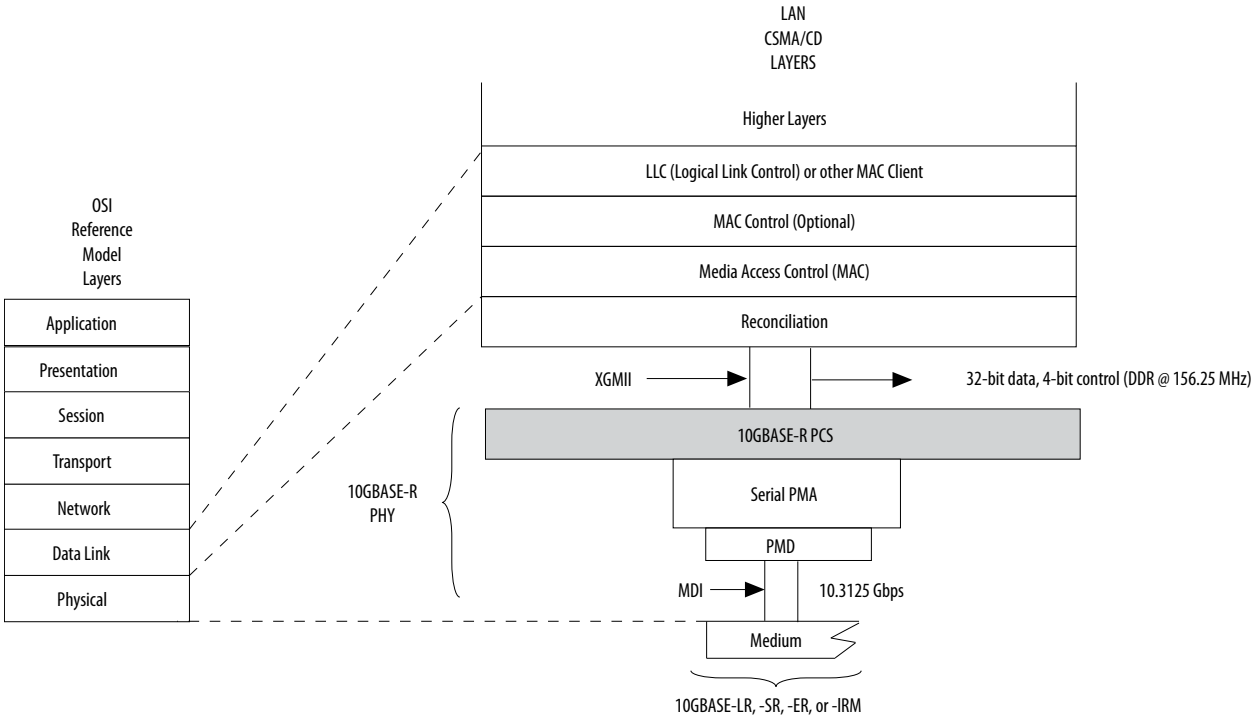
Arria V GT and ST devices support 10GBASE-R in PMA direct mode using soft PCS. 10GBASE-R is a specific physical layer implementation of the 10 Gigabit Ethernet link defined in clause 49 of the IEEE 802.3-2008 specification. The 10GBASE-R PHY uses the XGMII interface to connect to the IEEE802.3 media access control (MAC) and reconciliation sublayer (RS). The IEEE 802.3-2008 specification requires

each 10GBASE-R link to support a 10 Gbps data rate at the XGMII interface and a 10.3125 Gbps serial line rate with 64B/66B encoding.

The 10-Gbps transceivers transmitter in Arria V GT and ST devices are compliant with the 10GBASE-KR specification under the following conditions:

- A maximum of three full duplex channels within a bank are used. These three channels do not include a CMU PLL.
- The transmitted signal is 64B/66B encoded.

Figure 4-28: 10GBASE-R PHY Connection to IEEE802.3 MAC and RS



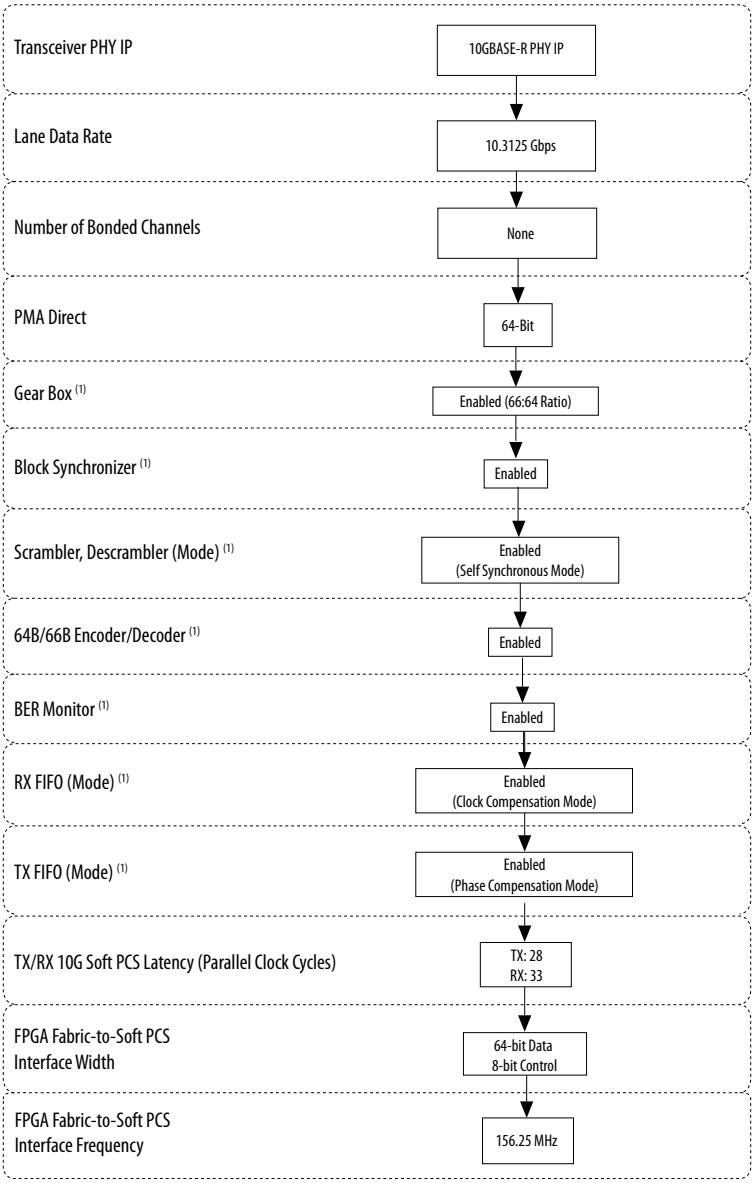
To implement a 10GBASE-R link, instantiate the **10GBASE-R PHY IP** core in the IP Catalog, under **Ethernet** in the Interfaces menu.

Related Information

Refer to the 10GBASE-R PHY IP Core chapter in the Altera Transceiver PHY IP Core User Guide.

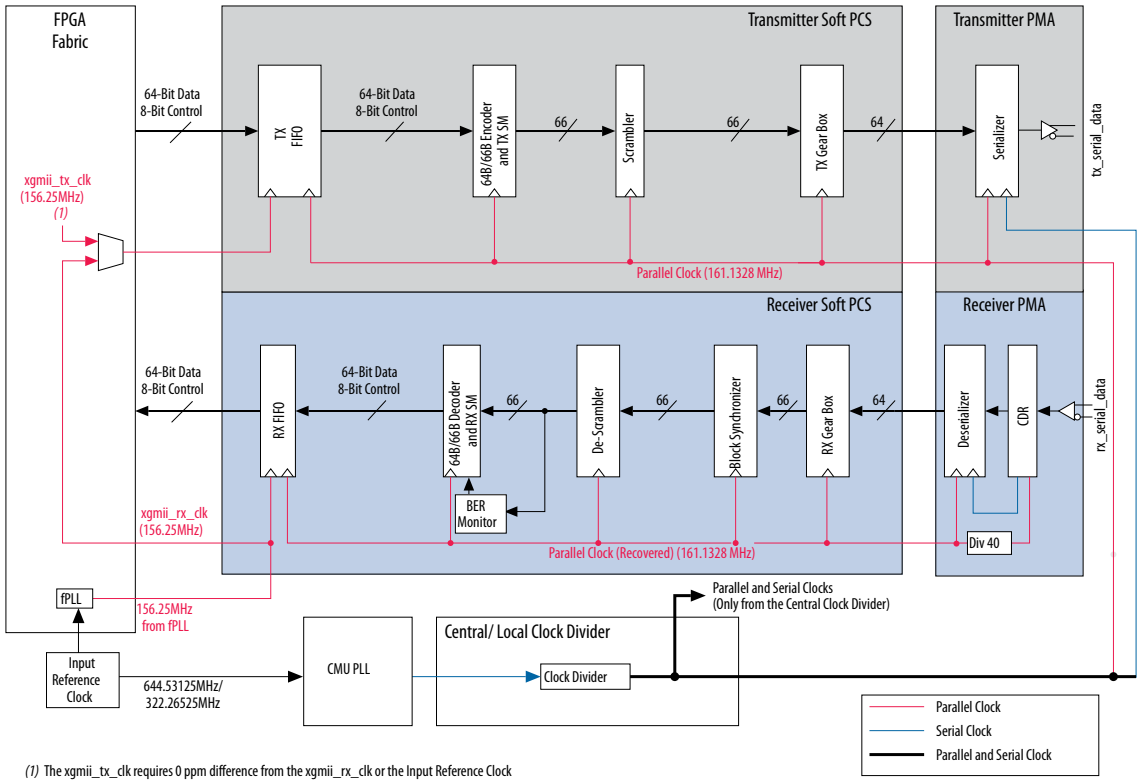
10GBASE-R Transceiver Datapath Configuration

Figure 4-29: 10GBASE-R Datapath Configuration for Arria V GT and ST Devices



Note:
1. Implemented in soft logic.

Figure 4-30: Transceiver Channel Datapath for a 10GBASE-R Configuration for Arria V GT and ST Devices



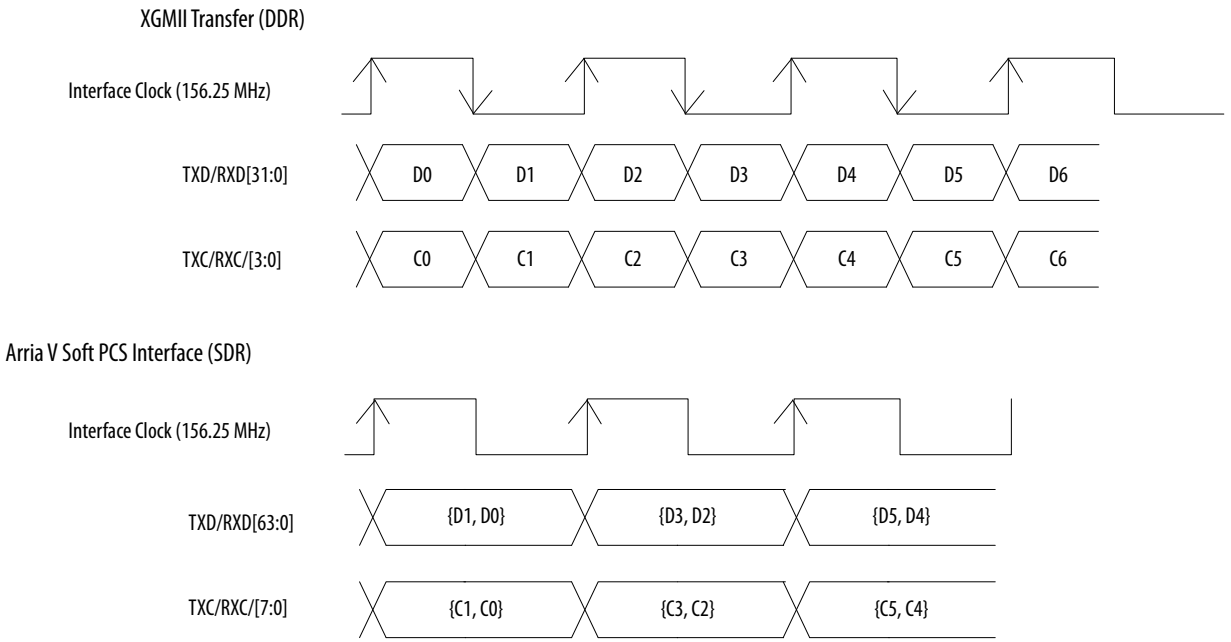
10GBASE-R Supported Features

64-Bit Single Data Rate (SDR) Interface to the MAC/RS

Clause 46 of the IEEE 802.3-2008 specification defines the XGMII interface between the 10GBASE-R soft PCS and the Ethernet MAC/RS. The XGMII interface defines the 32-bit data and 4-bit wide control character clocked between the MAC/RS and the soft PCS at both the positive and negative edge (double data rate – DDR) of the 156.25 MHz interface clock.

Arria V soft PCS does not support the XGMII interface to the MAC/RS as defined in the IEEE 802.3-2008 specification. Instead, they support a 64-bit data and 8-bit control SDR interface between the MAC/RS and the soft PCS.

Figure 4-31: XGMII Interface (DDR) versus Arria V Soft PCS Interface (SDR) for 10GBASE-R



64B/66B Encoding/Decoding

Arria V soft PCS in a 10GBASE-R configuration supports 64B/66B encoding and decoding as specified in Clause 49 of the IEEE802.3-2008 specification. The 64B/66B encoder receives 64-bit data and 8-bit control code from the transmitter FIFO and converts it into 66-bit encoded data. The 66-bit encoded data contains two overhead sync header bits that the receiver soft PCS uses for block synchronization and bit-error rate (BER) monitoring.

The 64B/66B encoding also ensures enough transitions on the serial data stream for the receiver clock data recovery (CDR) to maintain its lock on the incoming data.

Transmitter and Receiver State Machines

Arria V soft PCS in a 10GBASE-R configuration implement the transmitter and receiver state diagrams shown in Figure 49-14 and Figure 49-15 of the IEEE802.3-2008 specification.

Besides encoding the raw data specified in the 10GBASE-R soft PCS, the transmitter state diagram performs functions such as transmitting local faults (LBLOCK_T) under reset, as well as transmitting error codes (EBLOCK_T) when the 10GBASE-R soft PCS rules are violated.

Besides decoding the incoming data specified in the 10GBASE-R soft PCS, the receiver state diagram performs functions such as sending local faults (LBLOCK_R) to the MAC/RS under reset and substituting error codes (EBLOCK_R) when the 10GBASE-R soft PCS rules are violated.

Block Synchronizer

The block synchronizer in the receiver soft PCS determines when the receiver has obtained lock to the received data stream. It implements the lock state diagram shown in Figure 49-12 of the IEEE 802.3-2008 specification.

The block synchronizer provides a status signal to indicate whether it has achieved block synchronization or not.

Self-Synchronous Scrambling/Descrambling

The scrambler/descrambler blocks in the transmitter/receiver soft PCS implements the self-synchronizing scrambler/descrambler polynomial 1 + x39 + x58, as described in clause 49 of the IEEE 802.3-2008 specification. The scrambler/descrambler blocks are self-synchronizing and do not require an initialization seed. Barring the two sync header bits in each 66-bit data block, the entire payload is scrambled or descrambled.

BER Monitor

The BER monitor block in the receiver soft PCS implements the BER monitor state diagram shown in Figure 49-13 of the IEEE 802.3-2008 specification. The BER monitor provides a status signal to the MAC whenever the link BER threshold is violated.

The 10GBASE-R PHY IP core provides a status flag to indicate a high BER whenever 16 synchronization header errors are received within a 125 µs window.

Clock Compensation

The receiver FIFO in the receiver soft PCS datapath compensates up to ±100 ppm difference between the remote transmitter and the local receiver. The receiver FIFO does so by inserting Idles (/I/) and deleting Idles (/I/) or Ordered Sets (/O/), depending on the ppm difference.

Idle Insertion -- The receiver FIFO inserts eight /I/ codes following an /I/ or /O/ to compensate for clock rate disparity.

Idle (/I/) or Sequence Ordered Set (/O/) Deletion -- The receiver FIFO deletes either four /I/ codes or ordered sets (/O/) to compensate for the clock rate disparity. The receiver FIFO implements the following IEEE802.3-2008 deletion rules:

- Deletes the lower four /I/ codes of the current word when the upper four bytes of the current word do not contain a Terminate /T/ control character.
- Deletes the upper four /I/ codes of the current word when the previous word's lower four bytes do not contain a Terminate /T/ control character.
- Deletes one /O/ ordered set only when the receiver FIFO receives two consecutive /O/ ordered sets.

10GBASE-R Transceiver Clocking

The CMU PLL can be used as a TX PLL for Arria V GT and ST devices. Arria V GZ devices can use either the CMU PLL or the ATX PLL as a TX PLL.

Table 4-7: Input Reference Clock Frequency and Interface Speed Specifications for 10GBASE-R Configurations

Input Reference Clock Frequency (MHz)	FPGA Fabric-Soft PCS Interface Width	FPGA Fabric-Soft PCS Interface Frequency (MHz)
644.53125, 322.265625	64-bit data, 8-bit control	156.25

Serial Digital Interface

The Society of Motion Picture and Television Engineers (SMPTE) defines various Serial Digital Interface (SDI) standards for transmission of uncompressed video.

The following SMPTE standards are popular in video broadcasting applications:

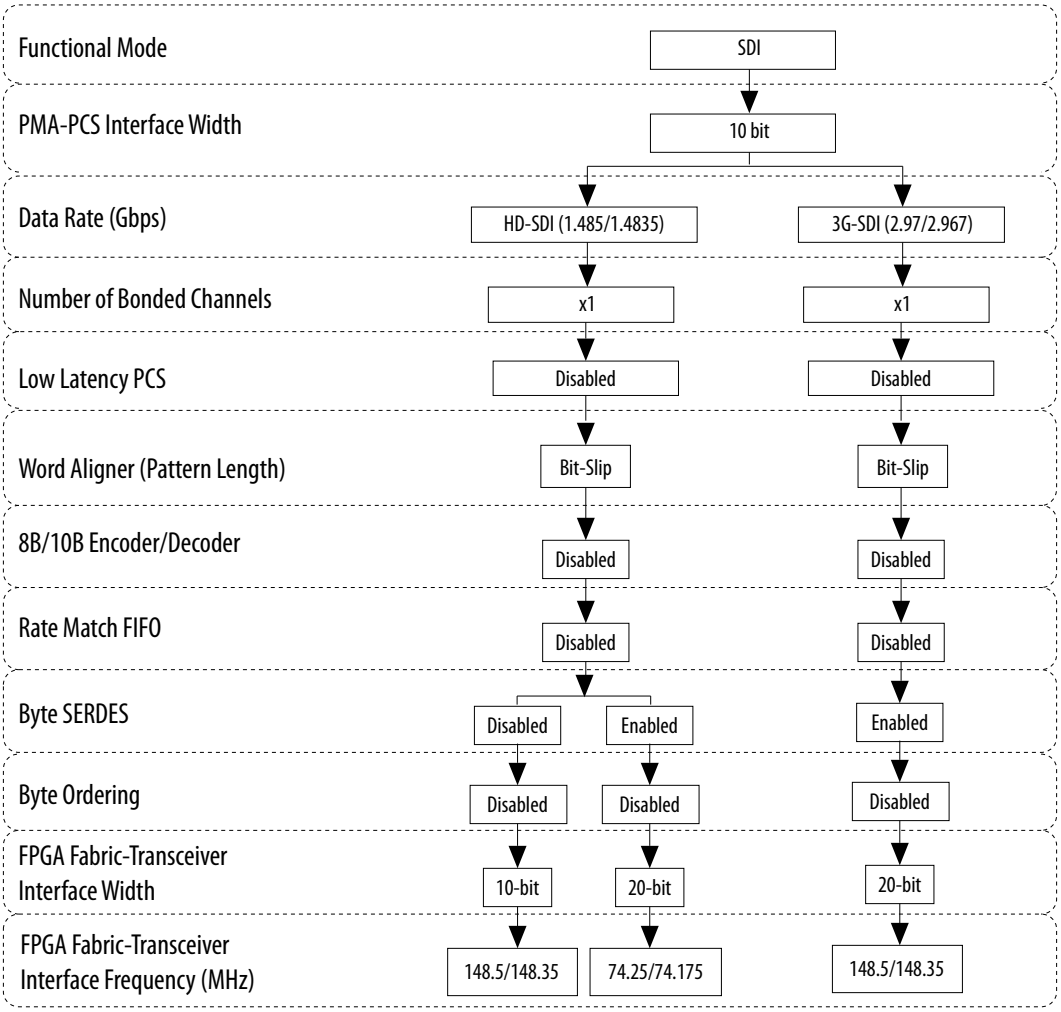
- SMPTE 259M standard - more popularly known as the standard-definition (SD) SDI; defined to carry video data at 270 Mbps
- SMPTE 292M standard - more popularly known as the high-definition (HD) SDI; defined to carry video data at either 1485 Mbps or 1483.5 Mbps
- SMPTE 424M standard - more popularly known as the third-generation (3G) SDI; defined to carry video data at either 2970 Mbps or 2967 Mbps

Configurations Supported in SDI Mode

Table 4-8: Configurations Supported in SDI Mode

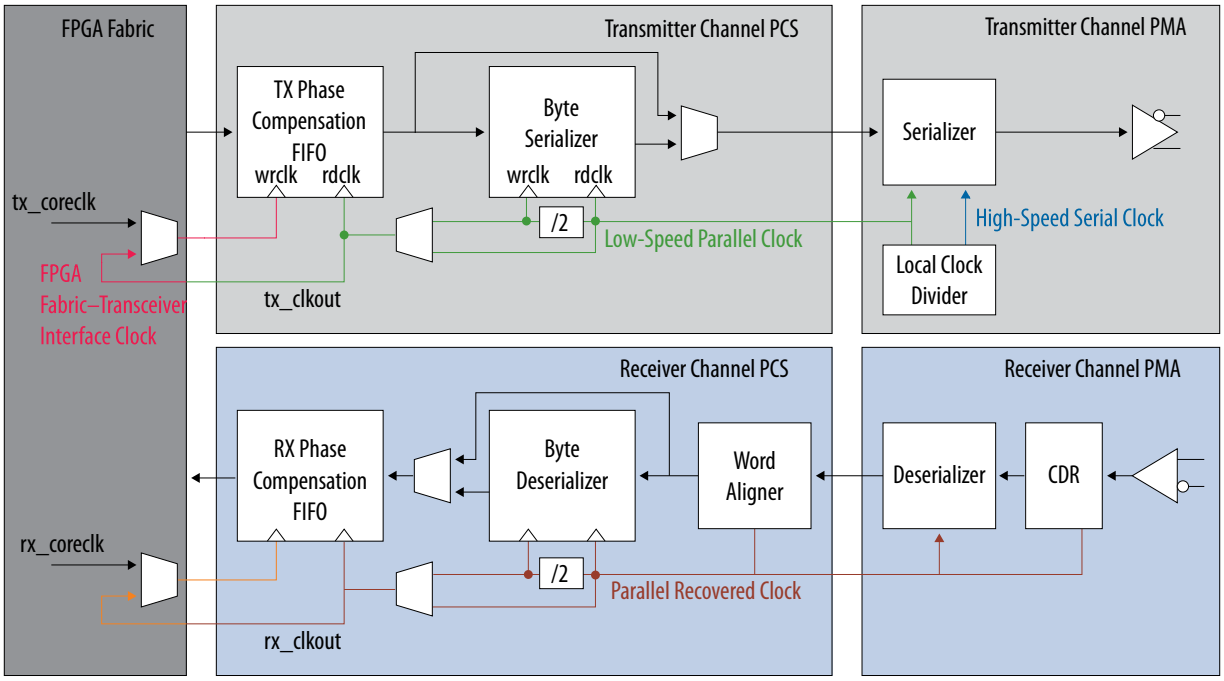
Configuration	Data Rate (Mbps)	REFCLK Frequencies (MHz)	FPGA Fabric-Transceiver Interface Width
HD	1,485	74.25, 148.5	10 bit and 20 bit
	1,483.5	74.175, 148.35	10 bit and 20 bit
3G	2,970	148.5, 297	Only 20-bit interfaces allowed in 3G
	2,967	148.35, 296.7	Only 20-bit interfaces allowed in 3G

Figure 4-32: SDI Mode



Serial Digital Interface Transceiver Datapath

Figure 4-33: SDI Mode Transceiver Datapath



Transmitter Datapath

The transmitter datapath in the HD-SDI configuration with a 10-bit wide FPGA fabric-transceiver interface consists of the transmitter phase compensation FIFO and the 10:1 serializer. In HD-SDI and 3G-SDI configurations with 20-bit wide FPGA fabric-transceiver interface, the transmitter datapath also includes the byte serializer.

Note: In SDI mode, the transmitter is purely a parallel-to-serial converter. You must implement the SDI transmitter functions, such as the scrambling and cyclic redundancy check (CRC) code generation, in the FPGA logic array.

Receiver Datapath

In the 10-bit channel width SDI configuration, the receiver datapath consists of the clock recovery unit (CRU), 1:10 deserializer, word aligner in bit-slip mode, and receiver phase compensation FIFO. In the 20-bit channel width SDI configuration, the receiver datapath also includes the byte deserializer.

Note: You must implement the SDI receiver functions, such as descrambling, framing, and CRC checker, in the FPGA logic array.

Receiver Word Alignment and Framing

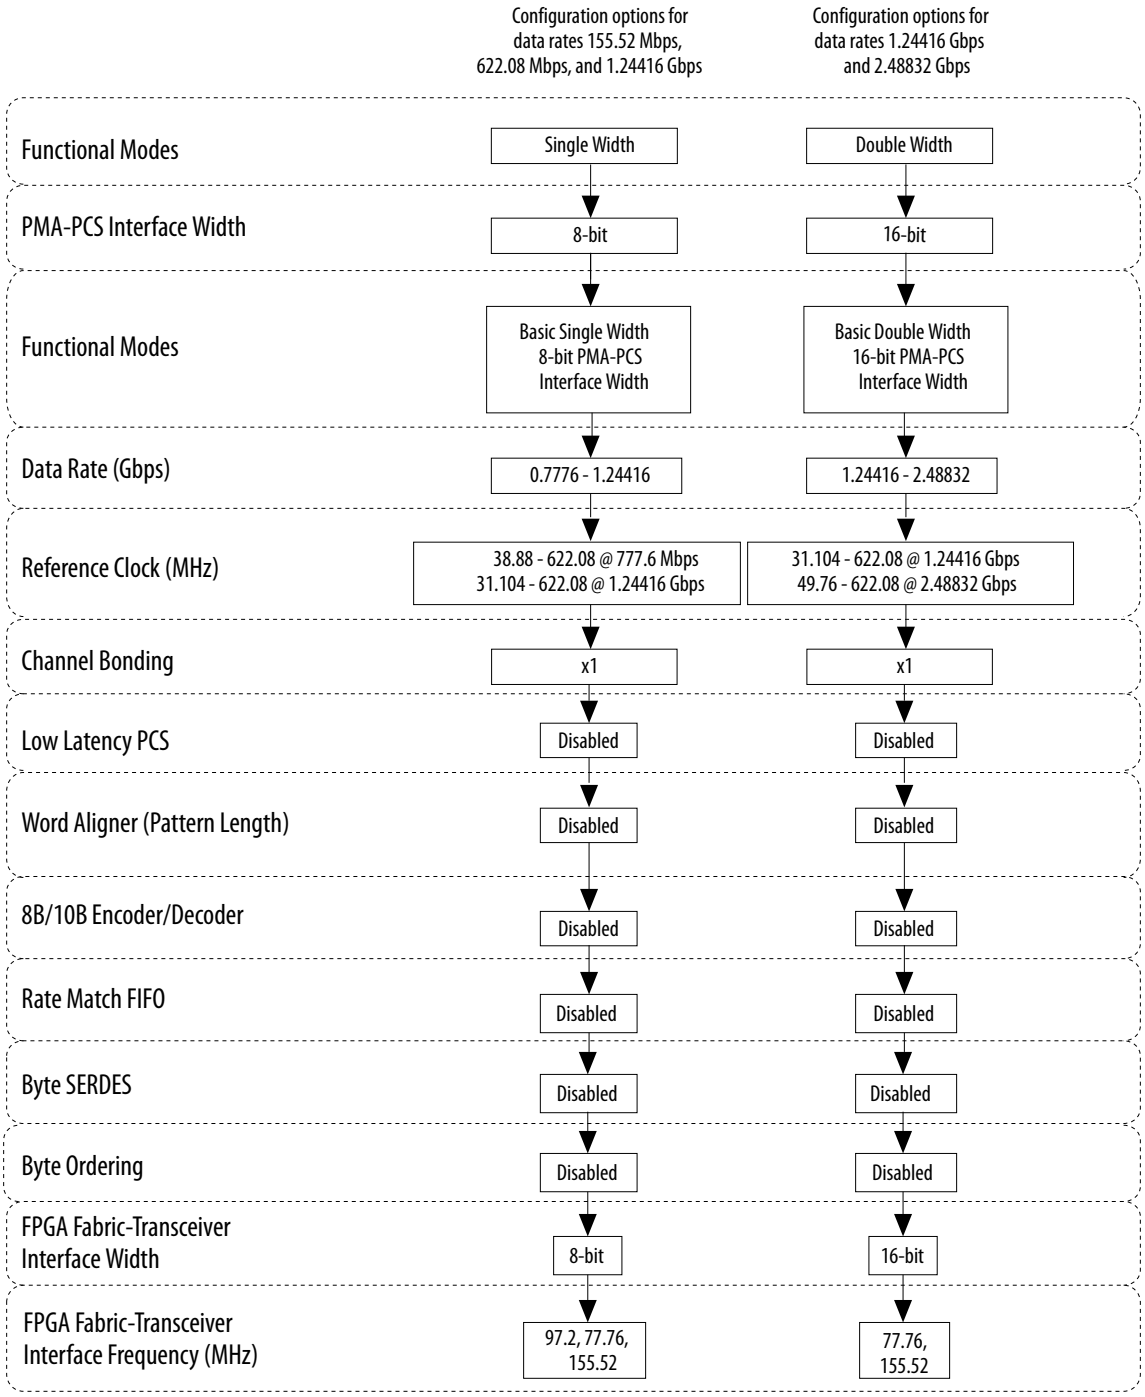
In SDI systems, the word aligner in the receiver datapath is not useful because the word alignment and framing happen after descrambling. Altera recommends that you drive the `rx_bitslip` signal of the PHY IP core low to avoid having the word aligner insert bits in the received data stream.

Gigabit-Capable Passive Optical Network (GPON)

The GPON protocol network provides optical fiber cabling and signals to the home and office using a point-to-multipoint scheme. GPON data rates of 155.52 Mbps, 622.08 Mbps, 1.24416 Gbps, and 2.48832 Gbps, with a reference clock of 155.52 MHz are supported. The minimum supported data rate is 600 Mbps, so a 5x oversampling factor is used for the GPON data rate of 155.52 Mbps, resulting in a data rate of 777.6 Mbps.

Note: You must build the oversampling at the PLD.

Figure 4-34: Configurations for the GPON Protocol

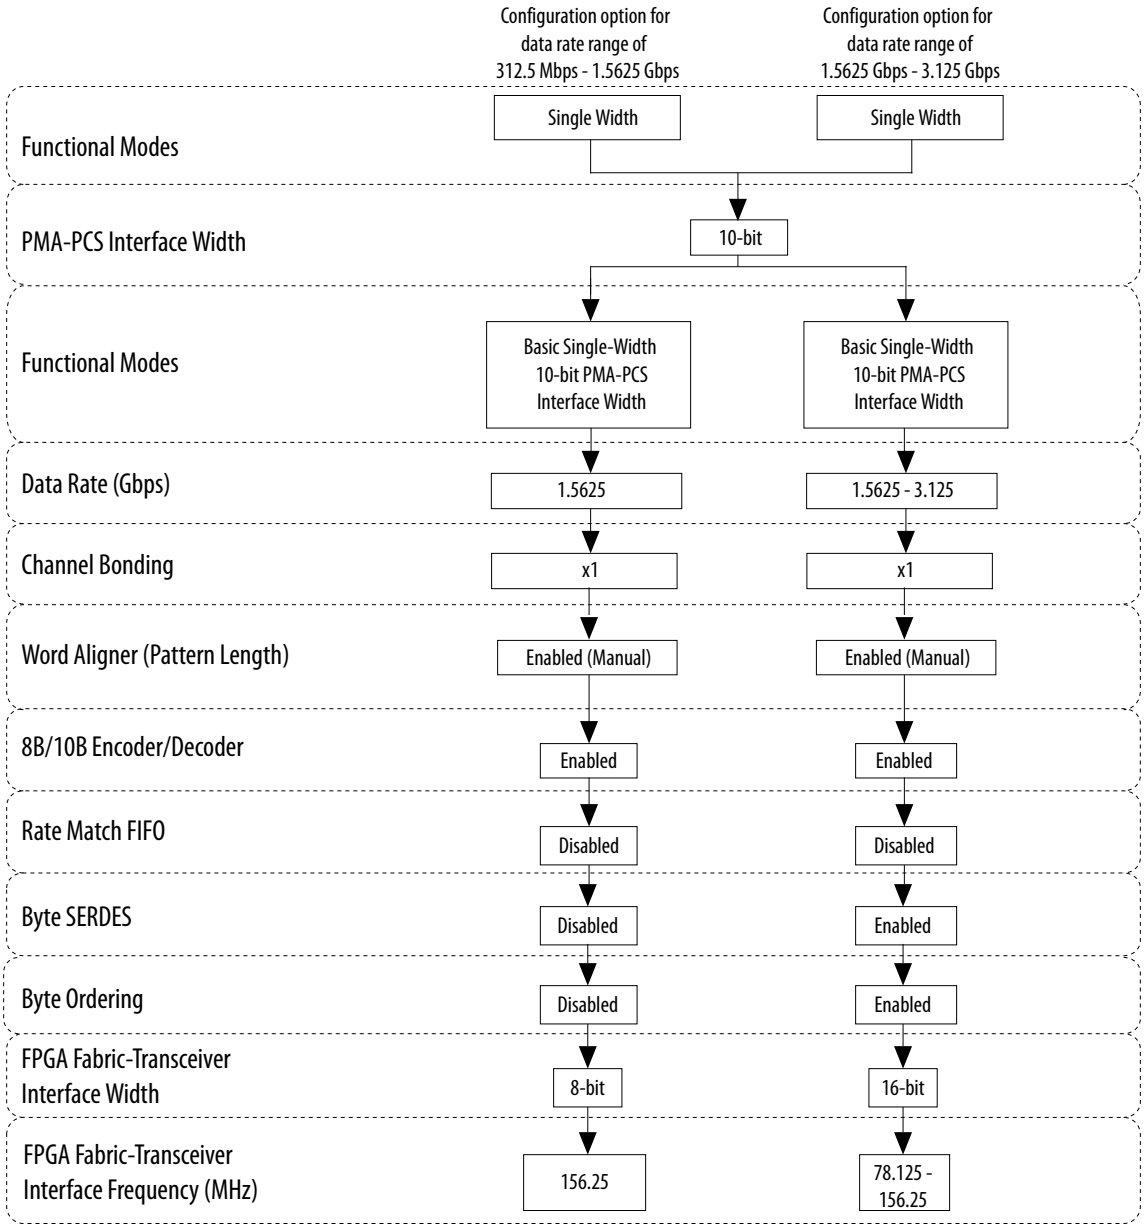


Serial Data Converter (SDC) JESD204

The SDC (JESD204) protocol conforms to JESD204, a JEDEC standard that enables a high-speed serial connection between analog-to-digital converters and logic devices using only a two-wire high-speed serial

interface. SDC (JESD204) data rate ranges of 312.5 Mbps to 3.125 Gbps are supported. The minimum supported data rate is 611 Mbps, so a 5x oversampling factor is used for the SDC (JESD204) data rate of 312.5 Mbps, resulting in a data rate of 1.5625 Gbps.

Figure 4-35: Configurations for the SDC (JESD204) Protocol



SATA and SAS Protocols

Serial ATA (SATA) and Serial Attached SCSI (SAS) are data storage protocol standards that have the primary function of transferring data (directly or otherwise) between the host system and mass storage devices, such as hard disk drives, optical drives, and solid-state disks.

These serial storage protocols offer several advantages over older parallel storage protocol (ATA and SCSI) interfaces:

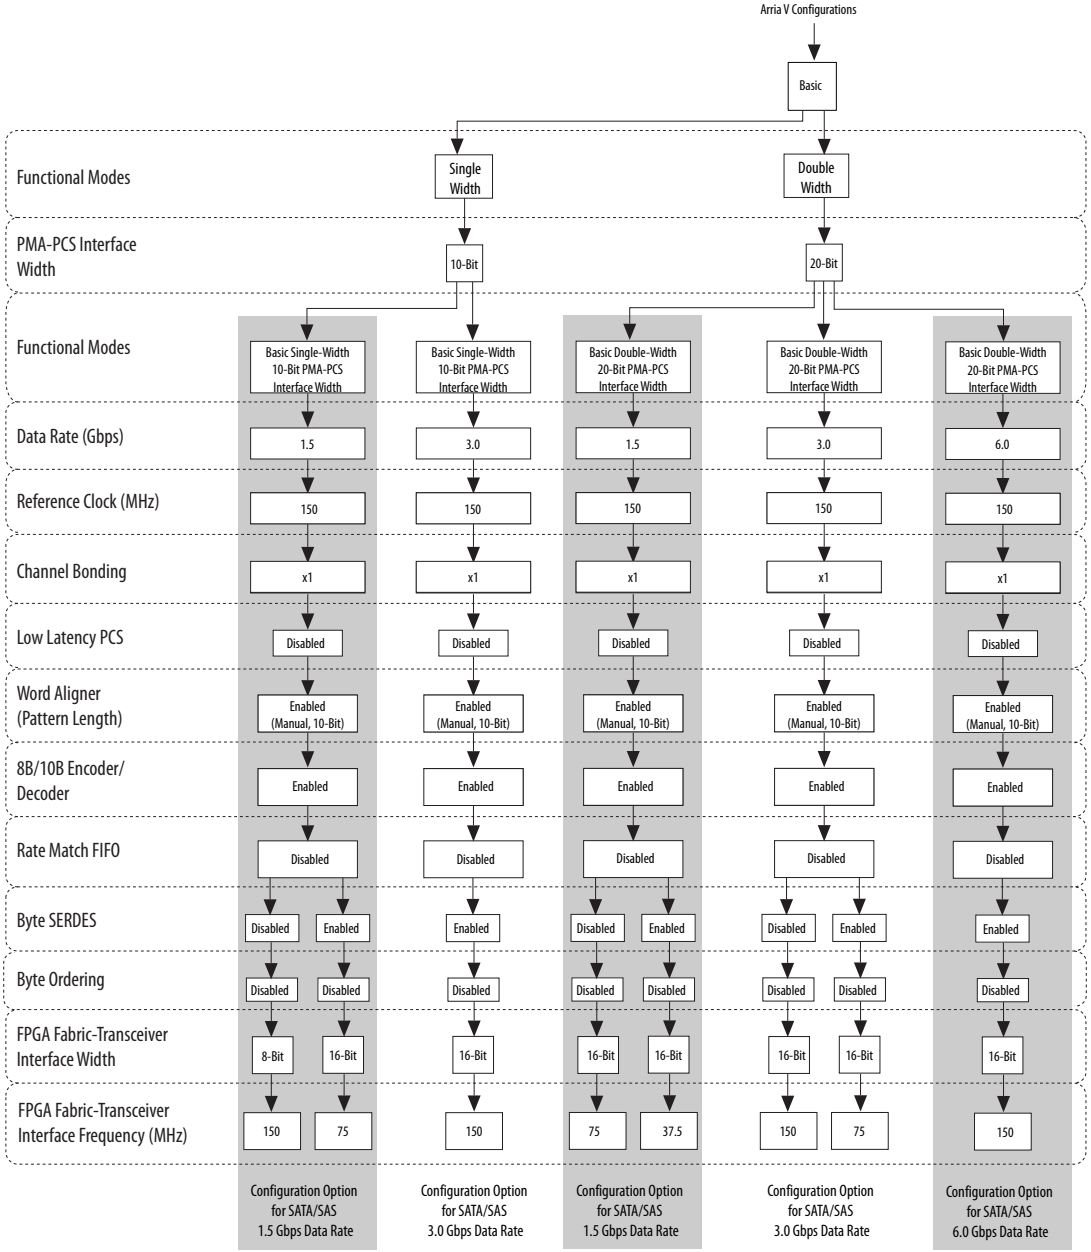
- Faster data transfer
- Hot swapping (when supported by the operating system)
- Thinner cables for more efficient air cooling
- Increased operation reliability

Table 4-9: Serial Data Rates for SATA and SAS Protocols

Protocol	SATA (Gbps)	SAS (Gbps)
Gen1	1.5	3.0
Gen2	3.0	6.0
Gen3	6.0	-

Figure 4-36: Configurations for the SATA and SAS Protocols

If you are configuring the SATA channel to support up to Gen3, set the base data rate to 6 Gbps and use the TX local clock divider to divide down to the Gen2 and Gen1 data rate.



Deterministic Latency Protocols—CPRI and OBSAI

A deterministic latency option is available for use in high-speed serial interfaces such as the Common Public Radio Interface (CPRI) and OBSAI Reference Point 3 (OBSAI RP3). Both CPRI and OBSAI RP3 protocols place stringent requirements on the amount of latency variation that is permissible through a link that implements these protocols.

Arria V GT devices also support 9.8304 Gbps CPRI with PMA direct configuration; PCS is implemented in soft logic.

Figure 4-37: Transceiver Datapath in Deterministic Latency Mode

Describes a soft PCS implementation for 9.8G CPRI.

Latency Uncertainty Removal with the Phase Compensation FIFO in Register Mode

To remove the latency uncertainty through the receiver's phase compensation FIFO, the receiver and transmitter phase compensation FIFOs are always set to register mode. In register mode, the phase compensation FIFO acts as a register and thereby removes the uncertainty in latency. The latency through the transmitter and receiver phase compensation FIFO in register mode is one clock cycle.

The following options are available:

- Single-width mode with 8-bit channel width and 8B/10B encoder enabled or 10-bit channel width with 8B/10B disabled
- Double-width mode with 16-bit channel width and 8B/10B encoder enabled or 20-bit channel width with 8B/10B disabled

Channel PLL Feedback for Deterministic Relationship

To implement the deterministic latency functional mode, the phase relationship between the low-speed parallel clock and channel PLL input reference clock must be deterministic. A feedback path is enabled to ensure a deterministic relationship between the low-speed parallel clock and channel PLL input reference clock.

To achieve deterministic latency through the transceiver, the reference clock to the channel PLL must be the same as the low-speed parallel clock. For example, if you need to implement a data rate of 1.2288 Gbps for the CPRI protocol, which places stringent requirements on the amount of latency variation, you must choose a reference clock of 122.88 MHz to allow the usage of a feedback path from the channel PLL. This feedback path reduces the variations in latency.

When you select this option, provide an input reference clock to the channel PLL that has the same frequency as the low-speed parallel clock.

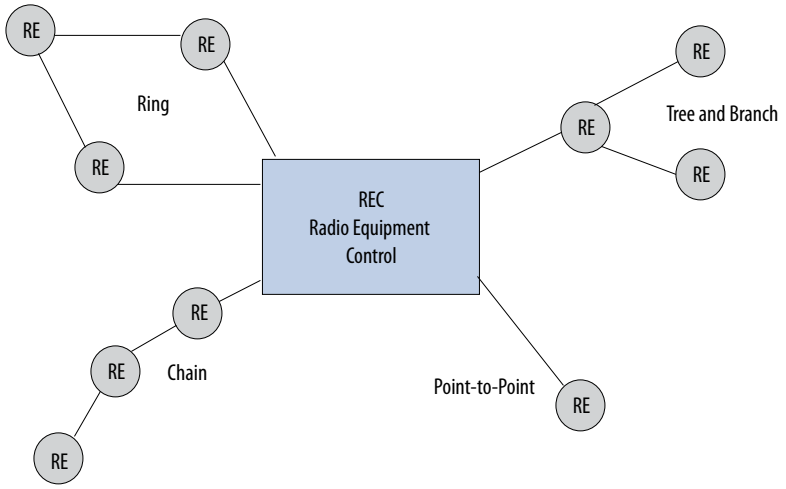
CPRI and OBSAI

Use the deterministic latency functional mode to implement protocols such as CPRI and OBSAI.

The CPRI interface defines a digital point-to-point interface between the Radio Equipment Control (REC) and the Radio Equipment (RE), allowing flexibility in either co-locating the REC and the RE, or a remote location of the RE.

Figure 4-38: CPRI Topologies

In most cases, CPRI links are between REC and RE modules or between two RE modules in a chain configuration.



If the destination for the high-speed serial data that leaves the REC is the first RE, it is a single-hop connection. If the serial data from the REC must traverse through multiple REs before reaching the destination RE, it is a multi-hop connection.

Remotely locating the RF transceiver from the main base station introduces a complexity with overall system delay. The CPRI specification requires that the accuracy of measurement of roundtrip delay on single-hop and multi-hop connections be within ±16.276 ns to properly estimate the cable delay.

For a single-hop system, this allows a variation in roundtrip delay of up to ±16.276 ns. However, for multi-hop systems, the allowed delay variation is divided among the number of hops in the connection—typically, equal to ±16.276 ns/(the number of hops) but not always equally divided among the hops.

Deterministic latency on a CPRI link also enables highly accurate triangulation of the location of the caller.

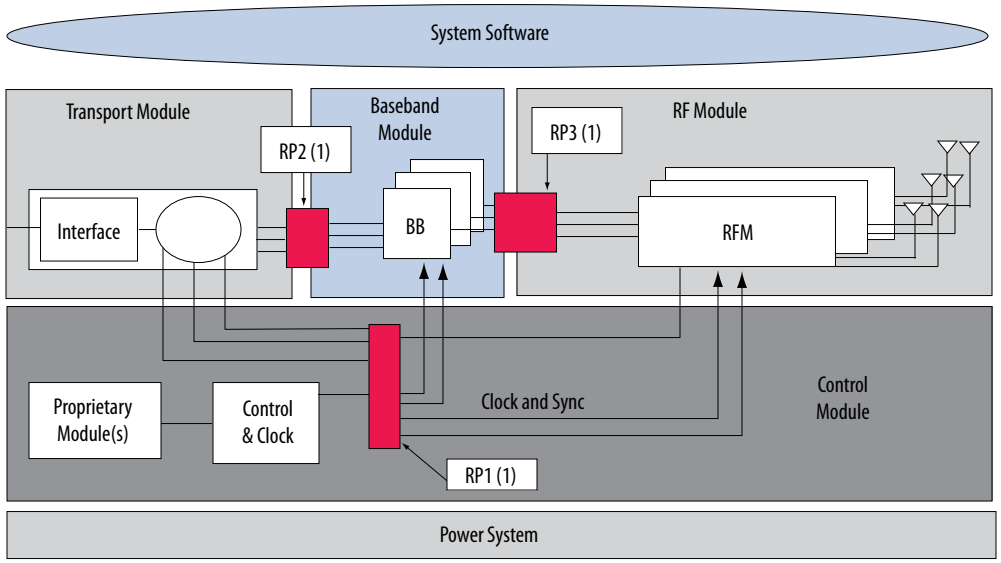
OBSAI was established by several OEMs to develop a set of specifications that can be used for configuring and connecting common modules into base transceiver stations (BTS).

The BTS has four main modules:

- Radio frequency (RF)
- Baseband
- Control
- Transport

In a typical BTS, the radio frequency module (RFM) receives signals using portable devices and converts the signals to digital data. The baseband module processes the encoded signal and brings it back to the baseband before transmitting it to the terrestrial network using the transport module. A control module maintains the coordination between these three functions.

Figure 4-39: Example of the OBSAI BTS Architecture



(1) RP = Reference Point

Using the deterministic latency option, you can implement the CPRI data rates in the following modes:

- Single-width mode—with 8/10-bit channel width
- Double-width mode—with 16/20-bit channel width

Table 4-10: Sample Channel Width Options for Supported Serial Data Rates

Serial Data Rate (Mbps)	Channel Width (FPGA-PCS Fabric)			
	Single-Width		Double-Width	
	8-Bit	16-Bit	16-Bit	32-Bit
614.4	Yes	Yes	No	No
1228.8	Yes	Yes	Yes	Yes
2457.6	No	Yes	Yes	Yes
3072	No	Yes	Yes	Yes
4915.2	No	No	No	Yes
6144	No	No	No	Yes
9830.4 (35)	N/A	N/A	N/A	N/A

Transceiver Architecture in Arria V Devices

CPRI Enhancements

The deterministic latency state machine in the word aligner reduces the known delay variation from the word alignment process and automatically synchronizes and aligns the word boundary by slipping a clock cycle in the deserializer. Incoming data to the word aligner is aligned to the boundary of the word alignment pattern (K28.5). User logic is not required to manipulate the TX bit slipper for constant round-trip delay. In manual mode, the TX bit slipper is able to compensate one unit interval (UI).

The word alignment pattern (K28.5) position varies in byte deserialized data. Delay variation is up to ½ parallel clock cycle. You must add in extra user logic to manually check the K28.5 position in byte deserialized data for the actual latency.

Figure 4-40: Deterministic Latency State Machine in the Word Aligner

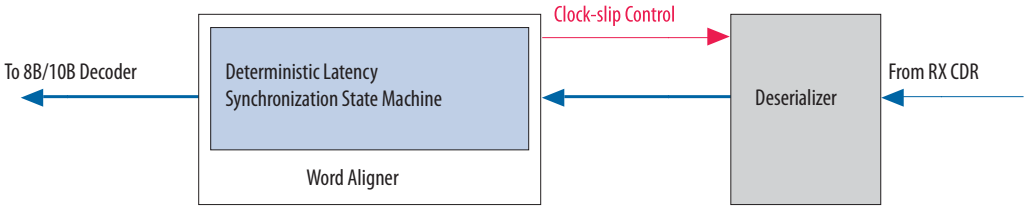

Table 4-11: Methods to Achieve Deterministic Latency Mode in Arria V Devices

Existing Feature [36]		Enhanced Feature [37]	
Description	Requirement	Description	Requirement
Manual alignment with bit position indicator provides deterministic latency. Delay variation up to 1 parallel clock cycle	Extra user logic to manipulate the TX bit slipper with a bit position indicator from the word aligner for constant total round-trip delay	Deterministic latency state machine alignment reduces the known delay variation in word alignment operation	None

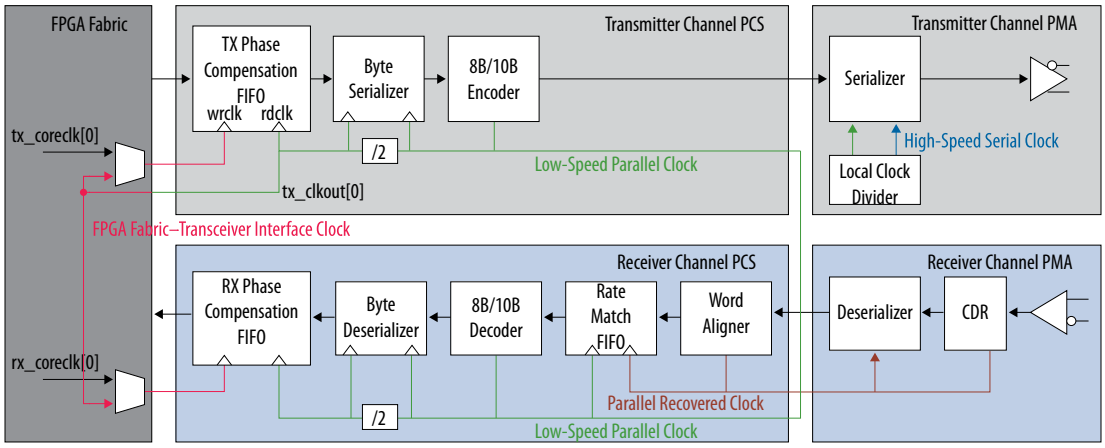
(37) Enhanced deterministic latency feature in Arria V devices.

Serial RapidIO

The RapidIO Trade Association defines a high-performance, packet-switched interconnect standard to pass data and control information between microprocessors, digital signal, communications, and network processors, system memories, and peripheral devices.

Figure 4-41: Transceiver Datapath in Serial RapidIO (SRIO) Mode



Arria V transceivers support SRIO physical layer specifications, versions 1.3 and 2.1, from 1.25 Gbps to 6.25 Gbps. The transceivers are compliant with x4 channel bonding, deskew state machine, and rate match FIFO.

Synchronization State Machine

The word aligner has a synchronization state machine that handles the receiver lane synchronization.

The synchronization state machine indicates synchronization when the receiver receives 127 K28.5 (10'b0101111100 or 10'b1010000011) synchronization code groups without receiving an intermediate invalid code group. After synchronization, the state machine indicates loss of synchronization when it detects three invalid code groups separated by less than 255 valid code groups, or when it is reset.

The `rx_syncstatus` port of each channel indicates the receiver synchronization:

- High—the lane is synchronized
- Low—the lane has fallen out of synchronization

Table 4-12: Synchronization State Machine Parameters in Serial RapidIO Mode

Parameters	Number
Number of valid K28.5 code groups received to achieve synchronization	127
Number of errors received to lose synchronization	3
Number of continuous good code groups received to reduce the error count by one	255

Rate Match FIFO

In SRIO mode, the rate match FIFO is capable of compensating for up to ±100 ppm (200 ppm total) difference between the upstream transmitter and the local receiver reference clock.

The rate match FIFO operation begins after the word aligner synchronization status, `rx_syncstatus`, goes high. When the rate matcher receives either of the two 10-bit control patterns followed by the respective 10-bit skip pattern, it inserts or deletes the 10-bit skip pattern as necessary to avoid the rate match FIFO from overflowing or under-running.

In SRIO mode, the rate match FIFO can delete or insert a maximum of one skip pattern from a cluster.

Transceiver Custom Configurations in Arria V Devices

5

2014.09.30

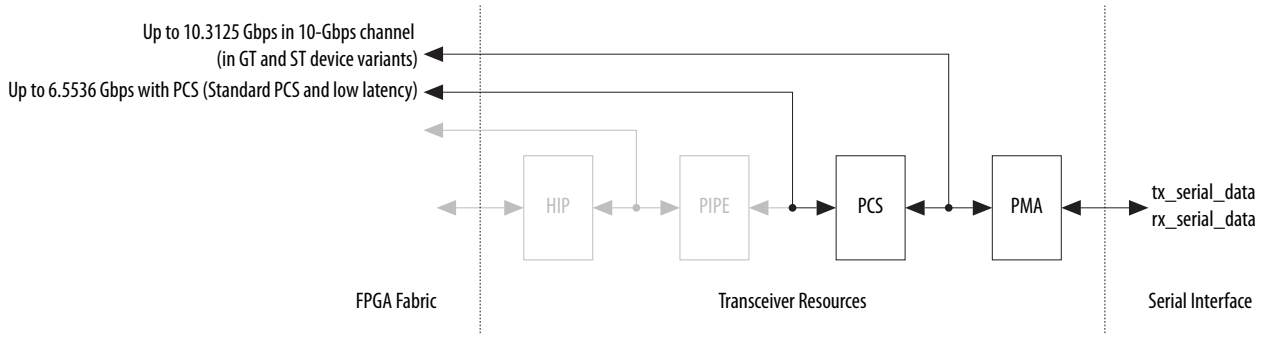
AV53005 Subscribe Send Feedback

For integration with the FPGA fabric, the full-duplex transceiver channel supports custom configuration with physical medium attachment (PMA), physical coding sublayer (PCS), and low latency custom configurations with the PMA and low latency PCS.

You can customize the transceiver with one of the following configurations:

- Standard PCS— Physical coding sublayer (PCS) and physical medium attachment (PMA)
- Standard PCS in low latency mode— Low latency PCS and PMA
- PMA Direct— PMA only

Figure 5-1: Custom Configuration Options



Related Information

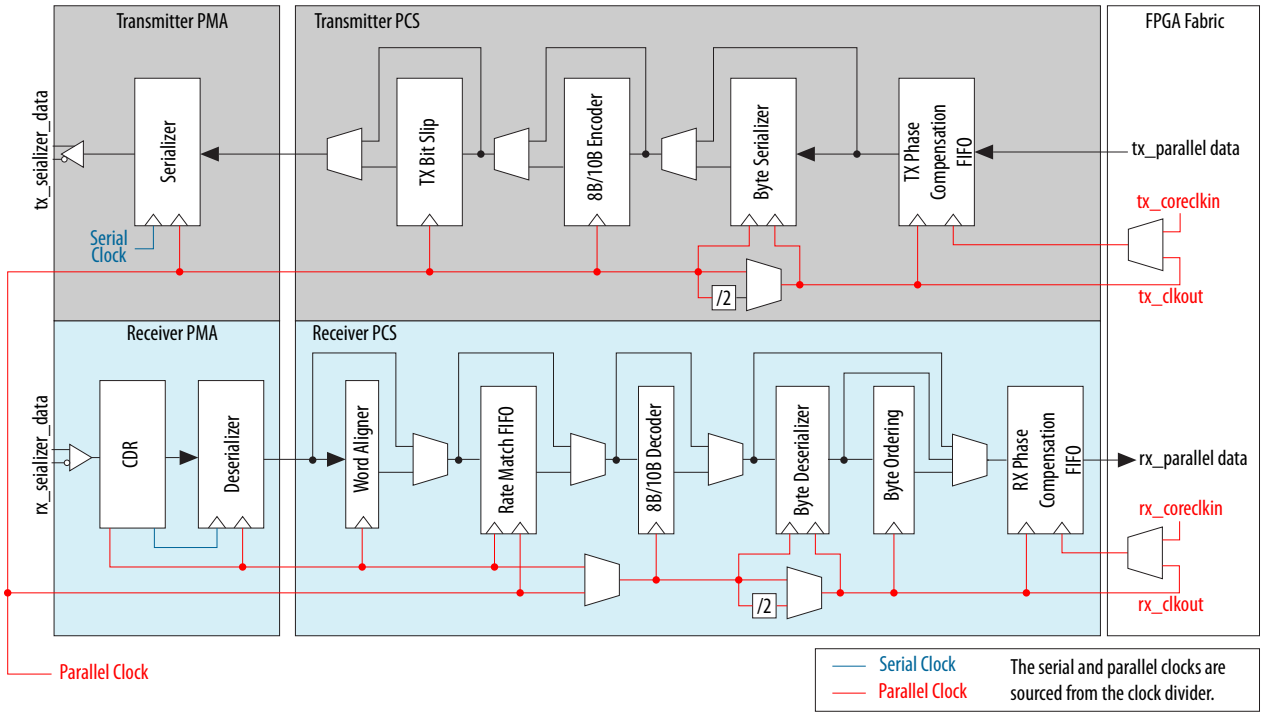
Arria V Device Handbook: Known Issues
Lists the planned updates to the *Arria V Device Handbook* chapters.

Standard PCS Configuration

In this configuration, you can customize the transceiver channel to include a PMA and PCS with functions that your application requires. The transceiver channel interfaces with the FPGA fabric through the PCS.

Figure 5-2: Complete Datapath in a Custom Configuration

Based on your application requirements, you can enable, modify, or disable the blocks, as shown in the following figure.



Custom Configuration Channel Options

There are multiple channel options when you use Custom Configuration.

The supported interface width varies depending on the usage of the byte serializer/deserializer (SERDES), and the 8B/10B encoder or decoder. The byte serializer or deserializer is assumed to be enabled. Otherwise, the maximum data rate supported is half of the specified value.

The maximum supported data rate varies depending on the customization.

Table 5-1: Maximum Supported Data Rate for Fastest Speed Grade Device (–4 Commercial) in Custom Configuration

The following table lists an example of the maximum supported data rate in various custom configurations with the PMA and PCS using the fastest speed grade device.

Data Configuration	PMA-PCS Interface Width	PCS-FPGA Fabric Interface Width		Maximum Data Rate (Mbps)
		8B/10B Enabled	8B/10B Disabled	
Single-width	8	—	8	1,500
			16	3,000
	10	8	10	1,875
		16	20	3,750

Data Configuration	PMA-PCS Interface Width	PCS-FPGA Fabric Interface Width		Maximum Data Rate (Mbps)
		8B/10B Enabled	8B/10B Disabled	
Double-width	16	—	16	2,621.44
			32	5,242.88
	20	16	20	3,276.8
		32	40	6,553.6

In all the supported configuration options of the channel, the transmitter bit-slip function is optional, where:

- The blocks shown as "Disabled" are not used but incur latency.
- The blocks shown as "Bypassed" are not used and do not incur any latency.
- The transmitter bit-slip is disabled.

Figure 5-3: Configuration Options for Custom Single-Width Mode (8-bit PMA–PCS Interface Width)

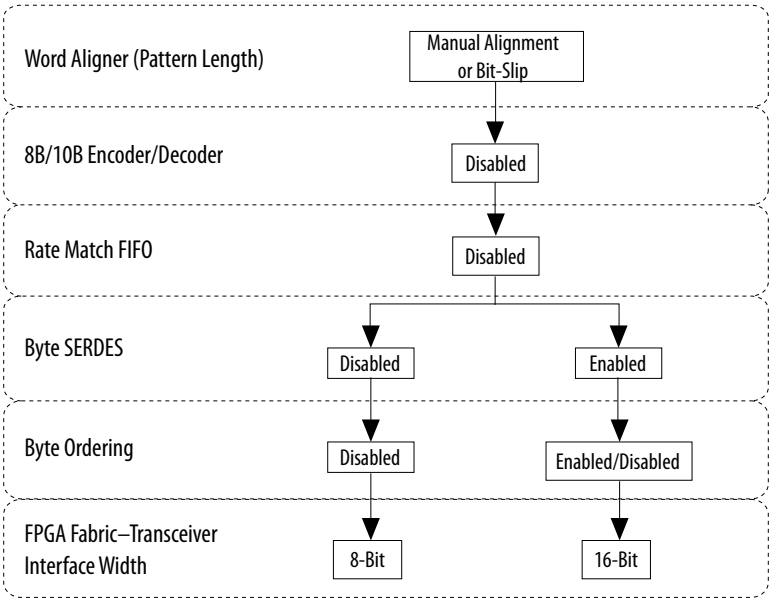


Figure 5-4: Configuration Options for Custom Single-Width Mode (10-bit PMA–PCS Interface Width)

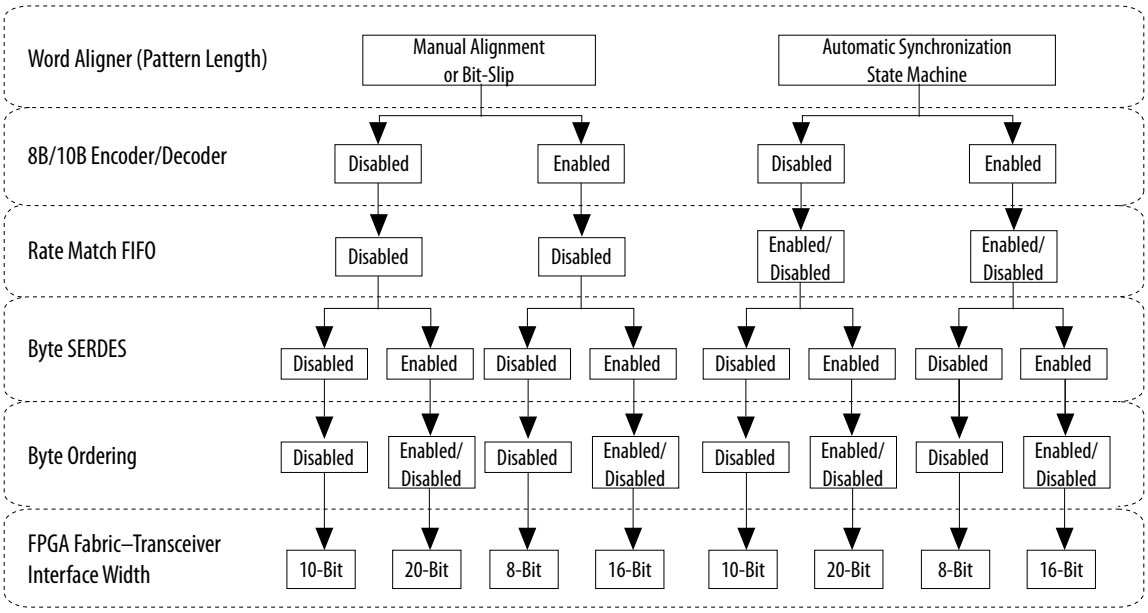

Figure 5-5: Configuration Options for Custom Double-Width Mode (16-bit PMA–PCS Interface Width)

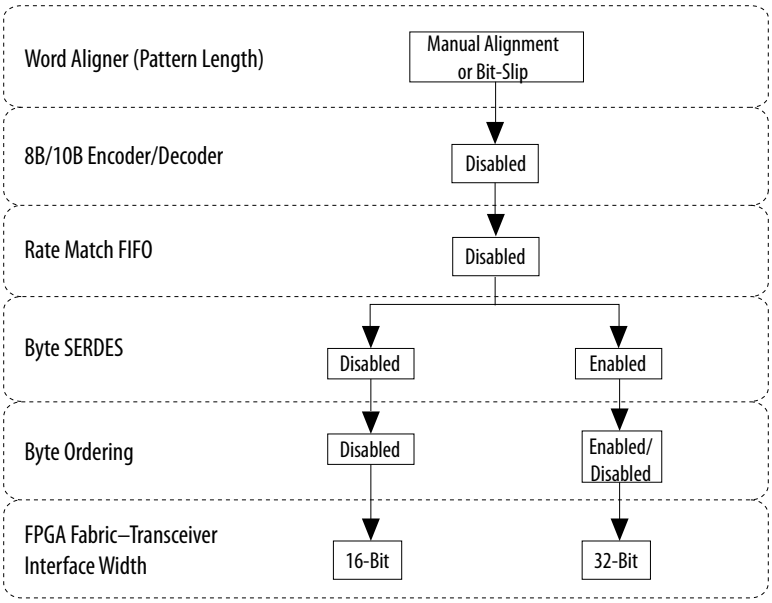

Figure 5-6: Configuration Options for Custom Double-Width Mode (20-bit PMA–PCS Interface Width)

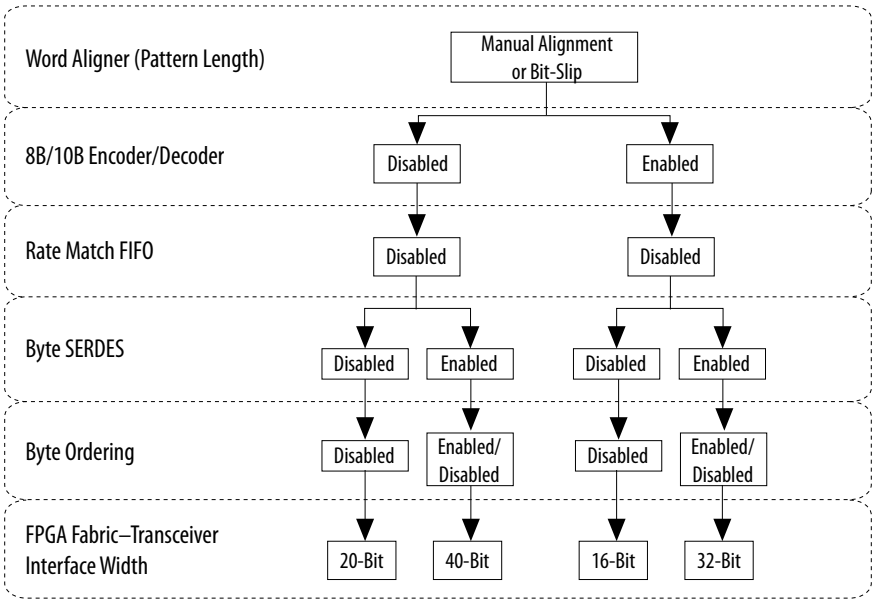


Rate Match FIFO in Custom Configuration

In a custom configuration, the 20-bit pattern for the rate match FIFO is user-defined. The FIFO operates by looking for the 10-bit control pattern followed by the 10-bit skip pattern in the data, after the word aligner restores the word boundary. After finding the pattern, the FIFO performs a skip pattern insertion or deletion to ensure that the FIFO does not underflow or overflow a given parts per million (ppm) difference between the clocks.

The rate match FIFO operation requires 8B/10B-coded data.

Rate Match FIFO Behaviors in Custom Single-Width Mode

The different operations available in custom single-width mode for the rate match FIFO are symbol insertion, symbol deletion, full condition, and empty condition.

Table 5-2: Rate Match FIFO Behaviors in Custom Single-Width Mode (10-bit PMA–PCS Interface Width)

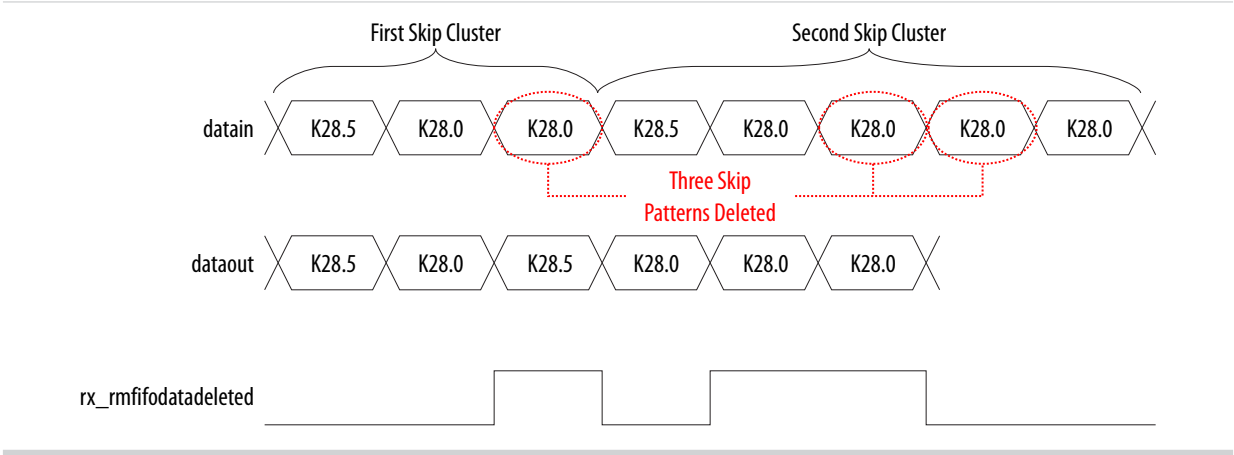
Operation	Behavior
Symbol Insertion	Inserts a maximum of four skip patterns in a cluster, only if there are no more than five skip patterns in the cluster after the symbol insertion.
Symbol Deletion	Deletes a maximum of four skip patterns in a cluster, only if there is one skip pattern left in the cluster after the symbol deletion.
Full Condition	Deletes the data byte that causes the FIFO to go full.

Operation	Behavior
Empty Condition	Inserts a /K30.7/ (9'h1FE) after the data byte that caused the FIFO to go empty.

In this example, /K28.5/ is the control pattern and neutral disparity /K28.0/ is the skip pattern. The first skip cluster has a /K28.5/ control pattern followed by two /K28.0/ skip patterns. The second skip cluster has a /K28.5/ control pattern followed by four /K28.0/ skip patterns. The rate match FIFO deletes only one /K28.0/ skip pattern from the first skip cluster to maintain at least one skip pattern in the cluster after deletion. Two /K28.0/ skip patterns are deleted from the second cluster for the three skip pattern deletion requirement.

Figure 5-7: Rate Match Deletion in Custom Single-Width Mode

The following figure shows an example of rate match FIFO deletion in the case where three skip patterns are required to be deleted.



In this example, /K28.5/ is the control pattern and neutral disparity /K28.0/ is the skip pattern. The first skip cluster has a /K28.5/ control pattern followed by three /K28.0/ skip patterns. The second skip cluster has a /K28.5/ control pattern followed by one /K28.0/ skip pattern. The rate match FIFO inserts only two /K28.0/ skip patterns into the first skip cluster to maintain a maximum of five skip patterns in the cluster after insertion. One /K28.0/ skip pattern is inserted into the second cluster for a total of three skip patterns to meet the insertion requirement.

Figure 5-8: Rate Match Insertion in Custom Single-Width Mode

The following figure shows an example of rate match FIFO insertion in the case where three skip patterns are required to be inserted.

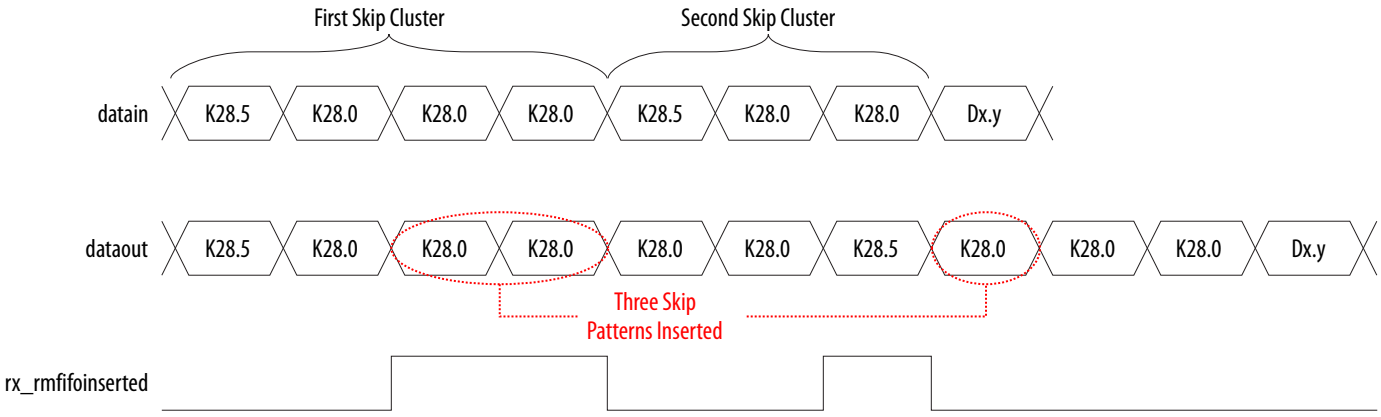


Figure 5-9: Rate Match FIFO Full Condition in Custom Single-Width Mode

The following figure shows the rate match FIFO full condition in custom single-width mode. The rate match FIFO becomes full after receiving data byte D4.

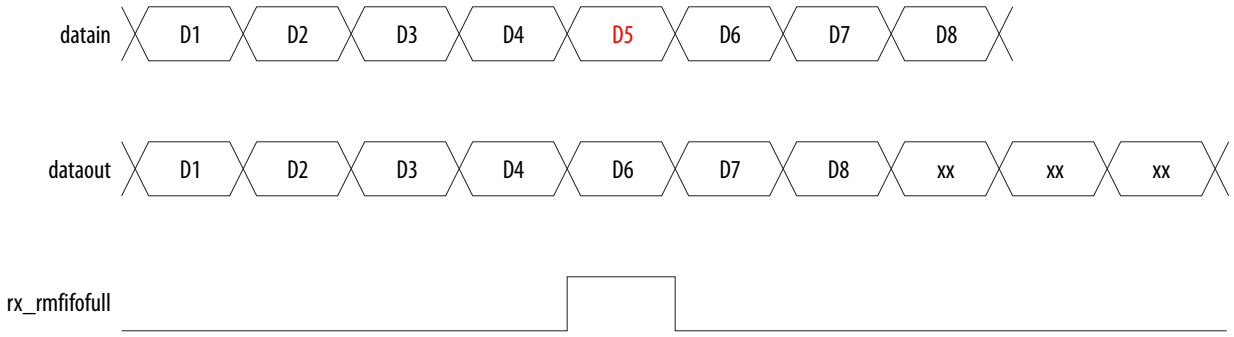

Figure 5-10: Rate Match FIFO Empty Condition in Custom Single-Width Mode

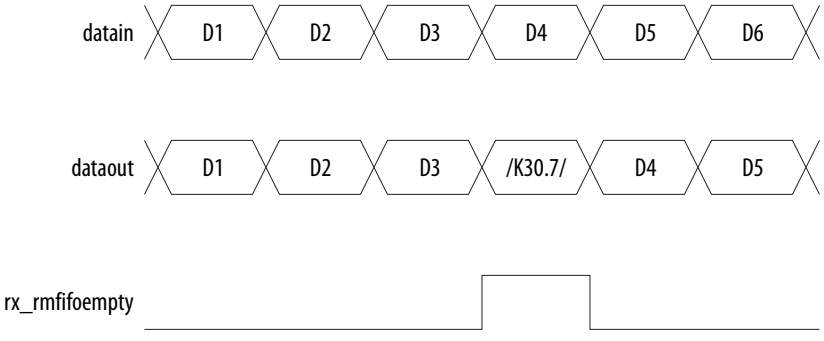
The following figure shows the rate match FIFO empty condition in custom single-width mode. The rate match FIFO becomes empty after reading out data byte D3.



Rate Match FIFO Behaviors in Custom Double-Width Mode

The different operations available in custom double-width mode for the rate match FIFO are symbol insertion, symbol deletion, full condition, and empty condition.

Table 5-3: Rate Match FIFO Behaviors in Custom Double-Width Mode (20-bit PMA–PCS Interface Width)

Operation	Behavior
Symbol Insertion	Inserts as many pairs (10-bit skip patterns at the LSByte and MSByte of the 20-bit word at the same clock cycle) of skip patterns as needed.
Symbol Deletion	Deletes as many pairs (10-bit skip patterns at the LSByte and MSByte of the 20-bit word at the same clock cycle) of skip patterns as needed.
Full Condition	Deletes the pair (20-bit word) of data bytes that causes the FIFO to go full.
Empty Condition	Inserts a pair of /K30.7/ ({9'h1FE, 9'h1FE}) after the data byte that causes the FIFO to go empty.

In this example, /K28.5/ is the control pattern and neutral disparity /K28.0/ is the skip pattern. The first skip cluster has a /K28.5/ control pattern in the LSByte and /K28.0/ skip pattern in the MSByte of a clock cycle followed by one /K28.0/ skip pattern in the LSByte of the next clock cycle. The rate match FIFO cannot delete the two skip patterns in this skip cluster because they do not appear in the same clock cycle. The second skip cluster has a /K28.5/ control pattern in the MSByte of a clock cycle followed by two pairs of /K28.0/ skip patterns in the next two cycles. The rate match FIFO deletes both pairs of /K28.0/ skip patterns (for a total of four skip patterns deleted) from the second skip cluster to meet the three skip pattern deletion requirement.

Figure 5-11: Rate Match Deletion in Custom Double-Width Mode

The following figure shows an example of rate match FIFO deletion in the case where three skip patterns are required to be deleted.

In this example, /K28.5/ is the control pattern and neutral disparity /K28.0/ is the skip pattern. The first skip cluster has a /K28.5/ control pattern in the LSByte and /K28.0/ skip pattern in the MSByte of a clock cycle followed by one /K28.0/ skip pattern in the LSByte of the next clock cycle. The rate match FIFO inserts pairs of skip patterns in this skip cluster to meet the three skip pattern insertion requirement.

Figure 5-12: Rate Match Insertion in Custom Double-Width Mode

The following figure shows an example of rate match FIFO insertion in the case where three skip patterns are required to be inserted.

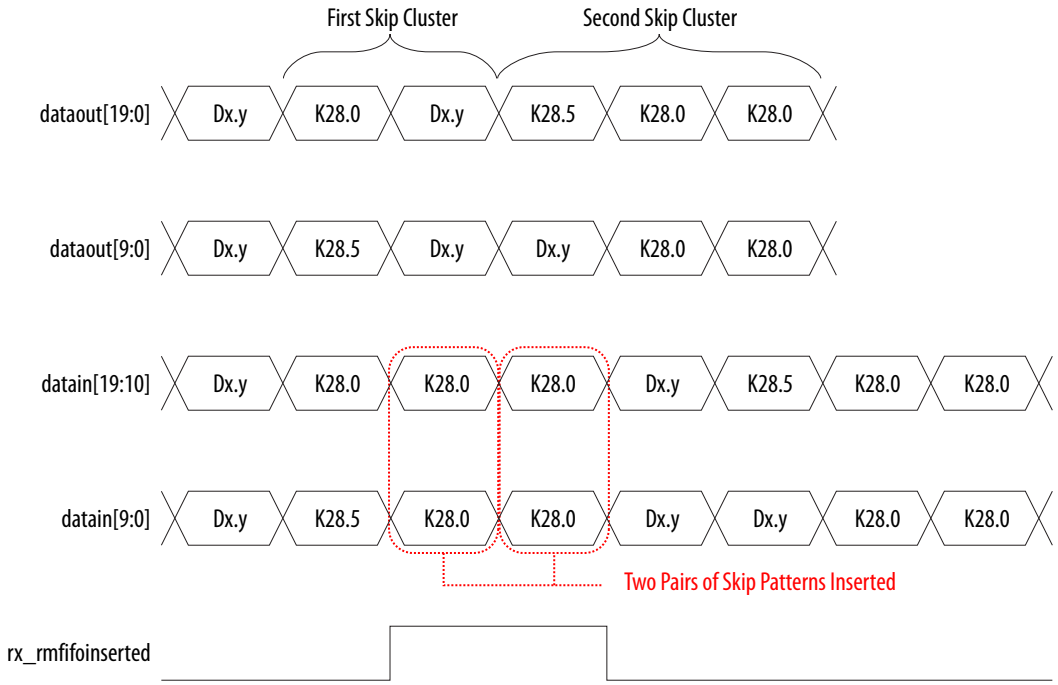


Figure 5-13: Rate Match FIFO Full Condition in Custom Double-Width Mode

The following figure shows the rate match FIFO full condition in custom double-width mode. The rate match FIFO becomes full after receiving the 20-bit word D5D6.

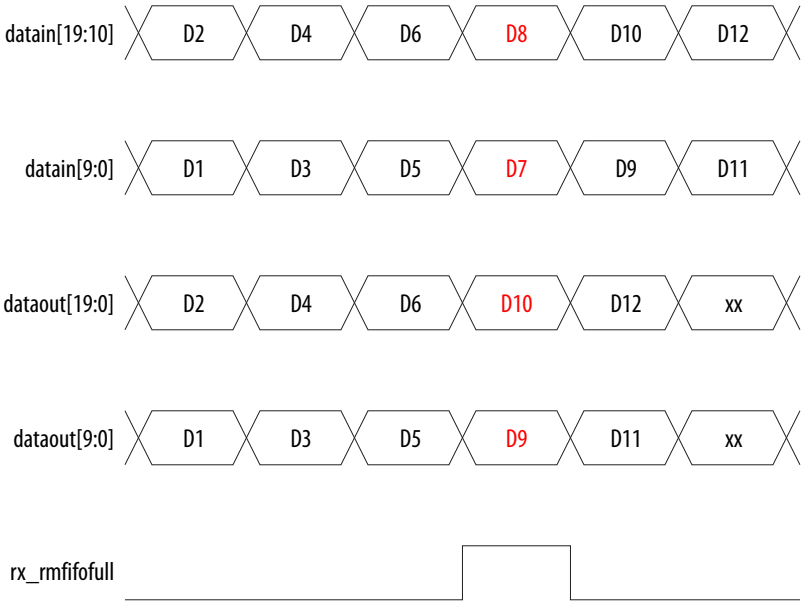

Figure 5-14: Rate Match FIFO Empty Condition in Custom Double-Width Mode

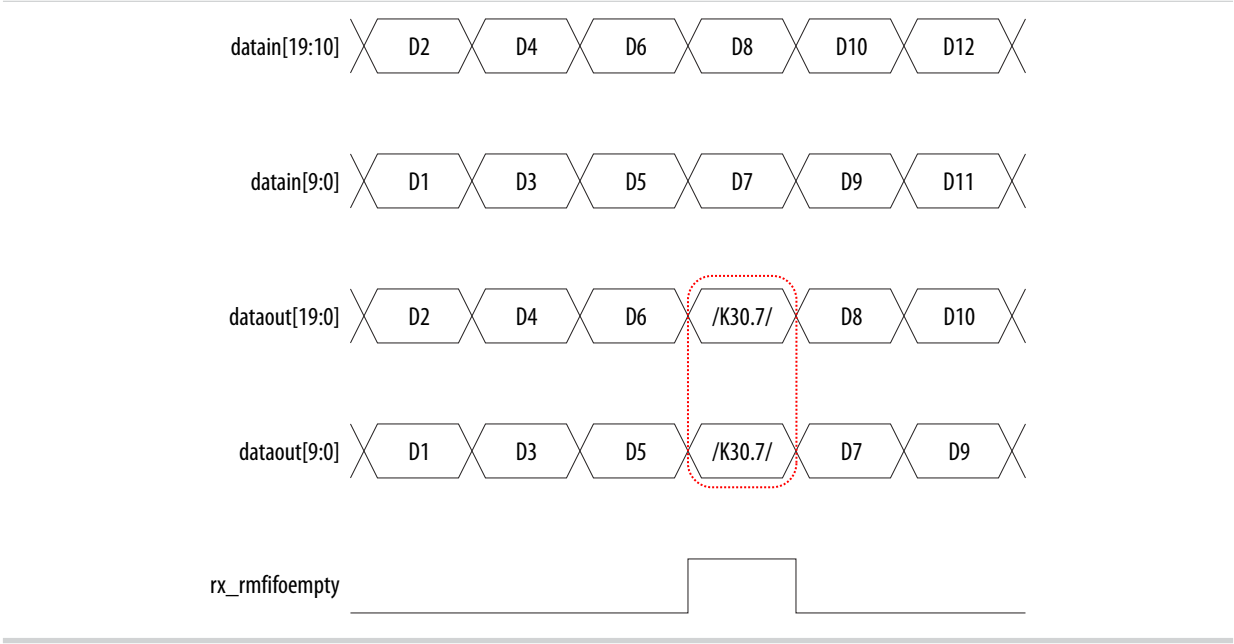
The following figure shows the rate match FIFO empty condition in custom double-width mode. The rate match FIFO becomes empty after reading out the 20-bit word D5D6.

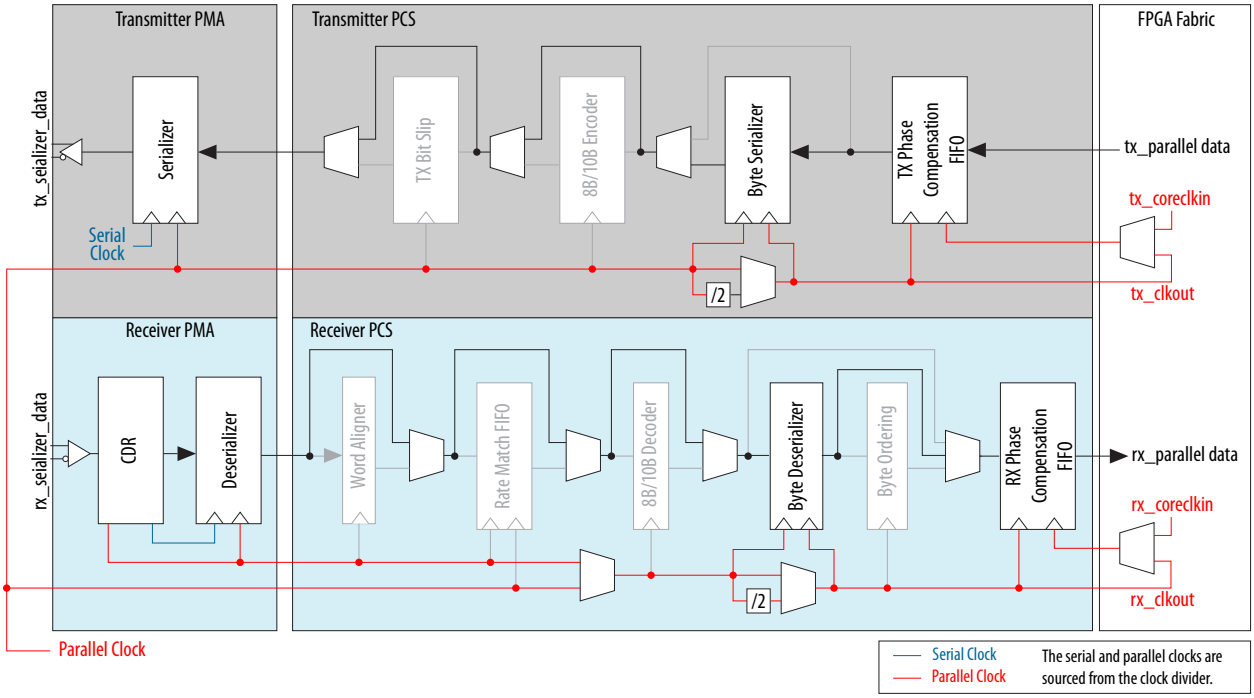


Standard PCS in Low Latency Configuration

In this configuration, you can customize the transceiver channel to include a PMA and PCS that bypasses most of the PCS logical functionality for a low latency datapath.

To provide a low latency datapath, the PCS includes only the phase compensation FIFO in phase compensation mode, and optionally, the byte serializer and byte deserializer blocks, as shown in the following figure. The transceiver channel interfaces with the FPGA fabric through the PCS.

Figure 5-15: Datapath in Low Latency Custom Configuration



The maximum supported data rate varies depending on the customization and is identical to the custom configuration except that the 8B/10B block is disabled

Low Latency Custom Configuration Channel Options

There are multiple channel options when you use Low Latency Custom Configuration.

In the following figures:

- The blocks shown as “Disabled” are not used but incur latency.
- The blocks shown as “Bypassed” are not used and do not incur any latency.
- The transmitter bit-slip is disabled.

Figure 5-16: Configuration Options for Low Latency Custom Single-Width Mode (8-bit PMA–PCS Interface Width)

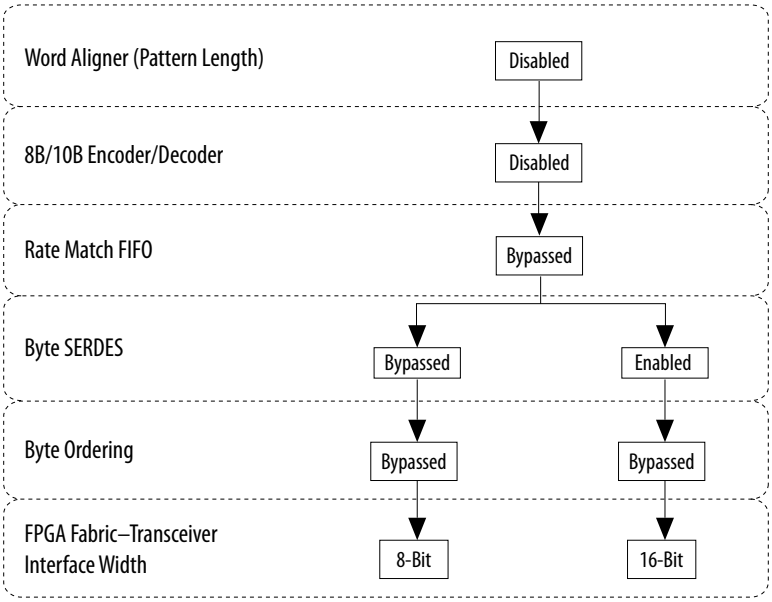


Figure 5-17: Configuration Options for Low Latency Custom Single-Width Mode (10-bit PMA–PCS Interface Width)

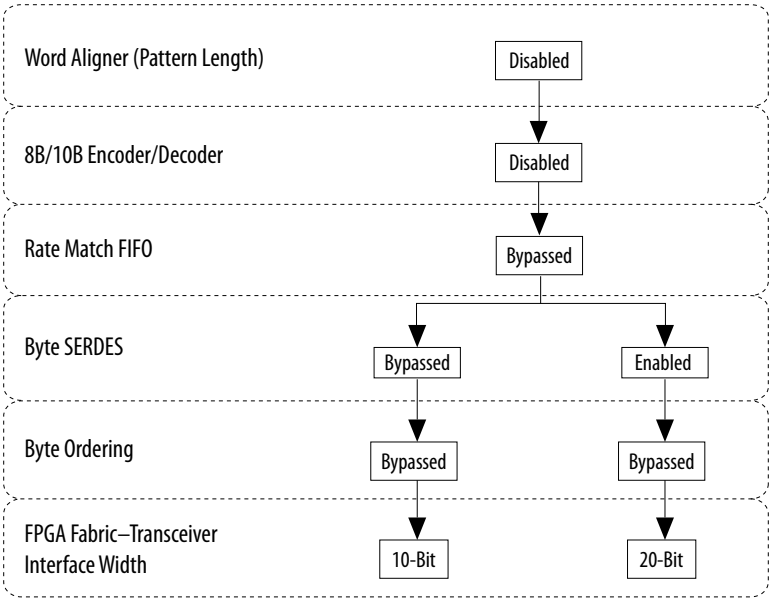

Figure 5-18: Configuration Options for Low Latency Custom Double-Width Mode (16-bit PMA–PCS Interface Width)

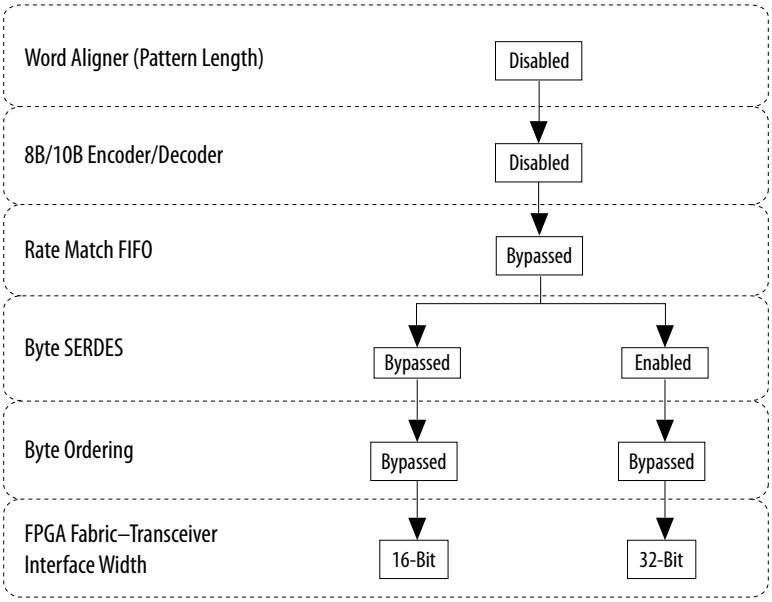

Figure 5-19: Configuration Options for Low Latency Custom Double-Width Mode (20-bit PMA–PCS Interface Width)

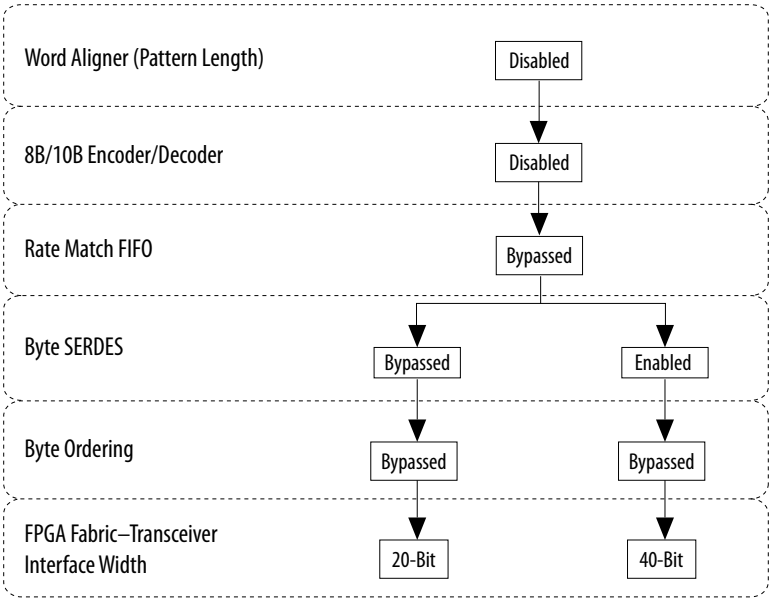

PMA Direct

You can customize the transceiver channel to include only the PMA, in a PMA Direct configuration for serial data rates up to 10.3125 Gbps.

In this configuration, the serializer and deserializer interface directly to the FPGA fabric, bypassing the PCS. The serializer and deserializer support 8-, 10-, 16-, 20-, 64-, and 80-bit configurations. You must implement the PCS functions in the FPGA fabric.

September 2014	2014.09.30	Updated the "Configuration Options for Custom Double-Width Mode (20-bit PMA-PCS Interface Width)" figure with change to Rate Match FIFO row.
March 2014	2014.03.07	Updated "Maximum Supported Data Rate for Fastest Speed Grade Device (–4 Commercial) in Custom Configuration" table.
May 2013	2013.05.06	Added link to the known document issues in the Knowledge Base.
November 2012	2012.11.19	Reorganized content and updated template.
June 2012	1.2	• Updated for the Quartus II software version 12.0. • Updated the “PCS Datapath Latency” section. • Updated the “PMA Direct Configuration” section. • Updated Figure 5–1 and Figure 5–14.

Date	Version	Changes
November 2011	1.1	Updated for the Quartus II software version 11.1.
August 2011	1.0	Initial release.

Transceiver Configurations in Arria V GZ Devices

6

2014.09.30

AV53008 Subscribe Send Feedback

Arria® V GZ devices have a dedicated transceiver physical coding sublayer (PCS) and physical medium attachment (PMA) circuitry.

To implement a protocol, use a PHY IP listed in **Table 6-12**.

Arria V GZ devices support the following communication protocols:

- 10GBASE-R and 10GBASE-KR
- Interlaken
- PCI Express® (PCIe®)—Gen1, Gen2, and Gen3
- CPRI and OBSAI—Deterministic Latency Protocols
- XAUI

Support for other communication protocols or user-defined protocols can be enabled with the following PHY IPs:

- Native PHY IP using standard PCS and 10G PCS hardware options including reconfigurability between different PCS options
- Custom PHY IP using the standard PCS in a custom datapath
- Low Latency PHY IP using the standard or 10G PCS in a low latency datapath configuration

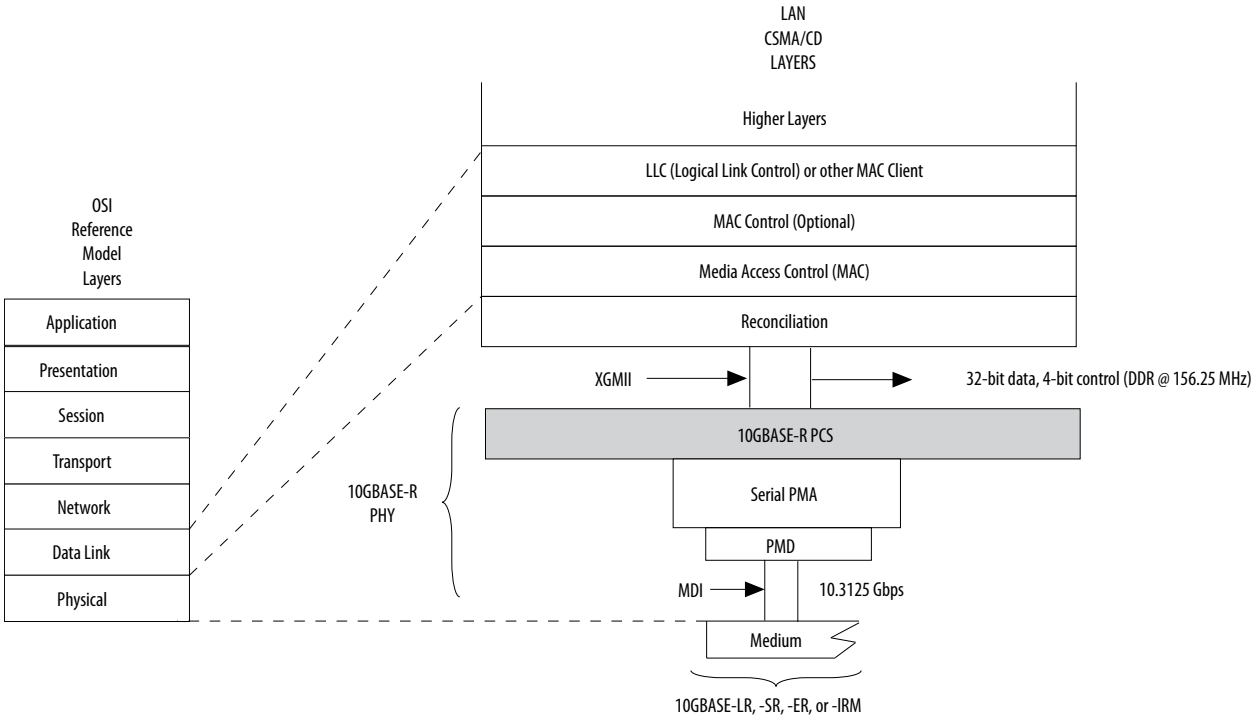
10GBASE-R and 10GBASE-KR

10GBASE-R is used in optical module LAN applications such as optical routers, servers, and switches, and 10GBASE-KR is used in electrical backplane applications such as blade servers using Arria V GZ transceivers.

10GBASE-R is a specific physical layer implementation of the 10 Gigabit Ethernet link defined in clause 49 of the IEEE 802.3-2008 specification. The 10GBASE-R PHY uses the XGMII interface to connect to the IEEE802.3 media access control (MAC) and reconciliation sublayer (RS). The IEEE 802.3-2008 specifica-

tion requires each 10GBASE-R link to support a 10 Gbps data rate at the XGMII interface and a 10.3125 Gbps serial line rate with 64B/66B encoding.

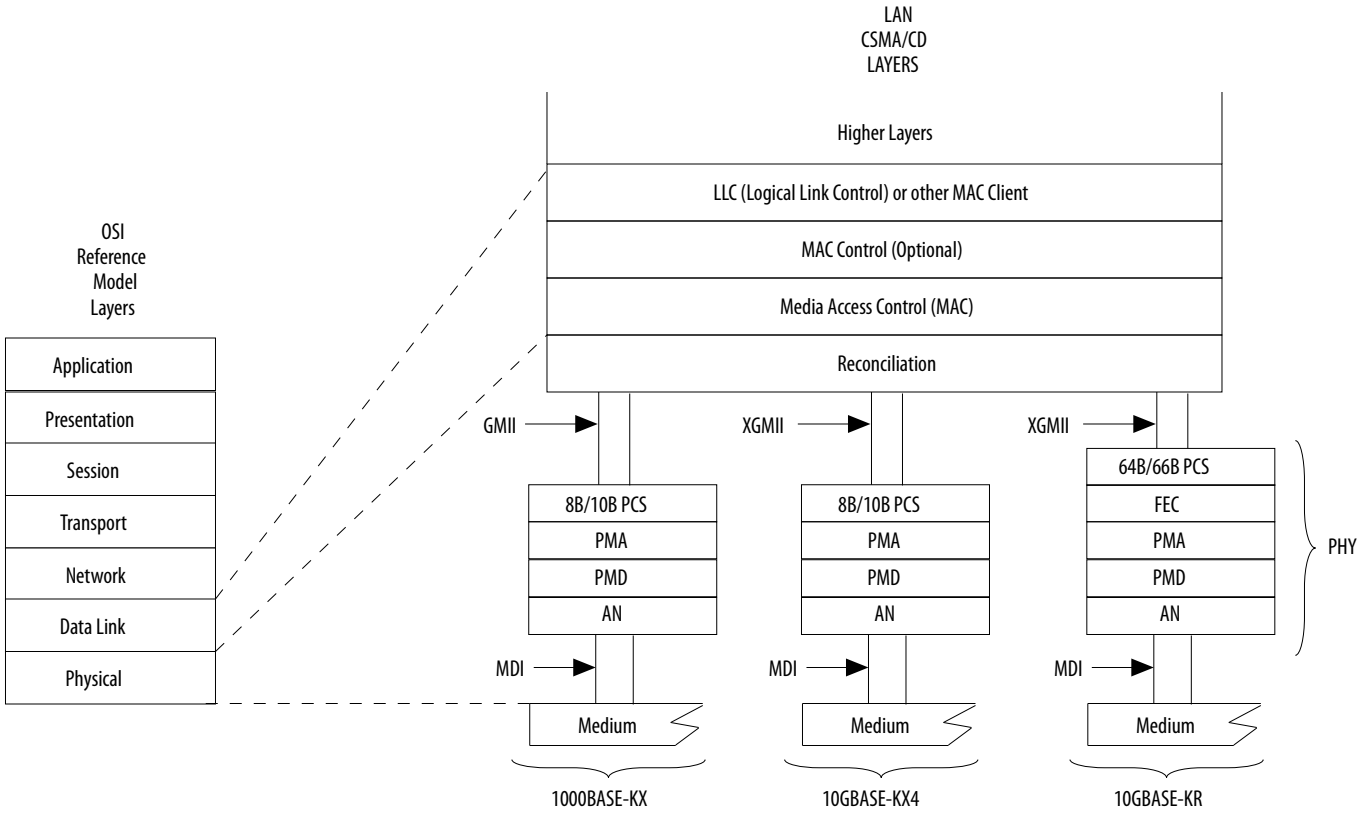
Figure 6-1: 10GBASE-R PHY Connection to IEEE802.3 MAC and RS



Note: To implement a 10GBASE-R link, instantiate the **10GBASE-R PHY IP** core in the IP Catalog, under **Ethernet** in the Interfaces menu.

The IEEE 802.3ap-2007 specification also requires each backplane link to support multi-data rates of 1Gbps and 10 Gbps speeds. 10GBASE-KR and 1000BASE-KX is the electrical backplane physical layer implementation for the 10 Gigabit and 1 Gigabit Ethernet link defined in clause 72 and clause 70 respectively of the IEEE 802.3ap-2007 specification. The 10 Gbps backplane ethernet 10GBASE-KR implementation uses the XGMII interface to connect to the reconciliation sublayer (RS) with 64B/66B PCS encoding, the optional Forward Error Correction (FEC), and Auto-Negotiation (AN) support to the Highest Common Denominator (HCD) technology with the partner link. The optional FEC, LT, and AN logic is implemented in the core fabric. The 1Gbps backplane ethernet 1000BASE-KX implementation uses the GMII interface to connect to the reconciliation sublayer (RS) with 8B/10B PCS encoding and Auto-Negotiation support to the HCD technology with the partner link.

Figure 6-2: 10GBASE-KR PHY Connection to IEEE802.3 MAC and RS



Note: To implement a 10GBASE-KR link with 1000BASE-KX support, instantiate the **1G/10GbE PHY IP** and **10GBASE-KR PHY IP** cores in the IP Catalog, under **Ethernet** in the Interfaces menu.

An additional license is required in order to use the 1G/10GbE and 10GBASE-KR PHY IP Core which also supports 10GBASE-R and 1000BASE-X links and auto-negotiation between the 10 Gigabit and 1 Gigabit Ethernet data rates.

10GBASE-R and 10GBASE-KR Transceiver Datapath Configuration

The following figures show the transceiver blocks and settings enabled in 10GBASE-R and 10GBASE-KR configurations.

10GBASE-R

Figure 6-3: 10GBASE-R Datapath Configuration

The blocks shown as "Disabled" are not used, but incur latency. The blocks shown as "Bypassed" are not used and do not incur latency.

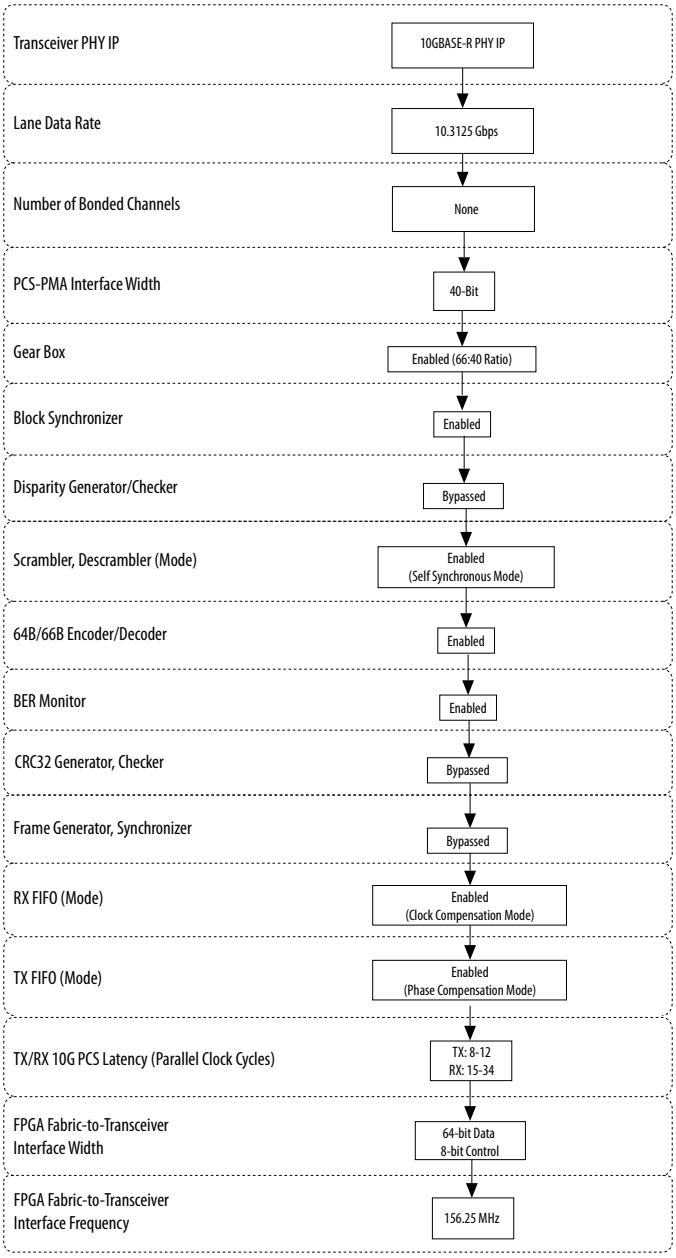

Figure 6-4: Transceiver Channel Datapath for a 10GBASE-R Configuration

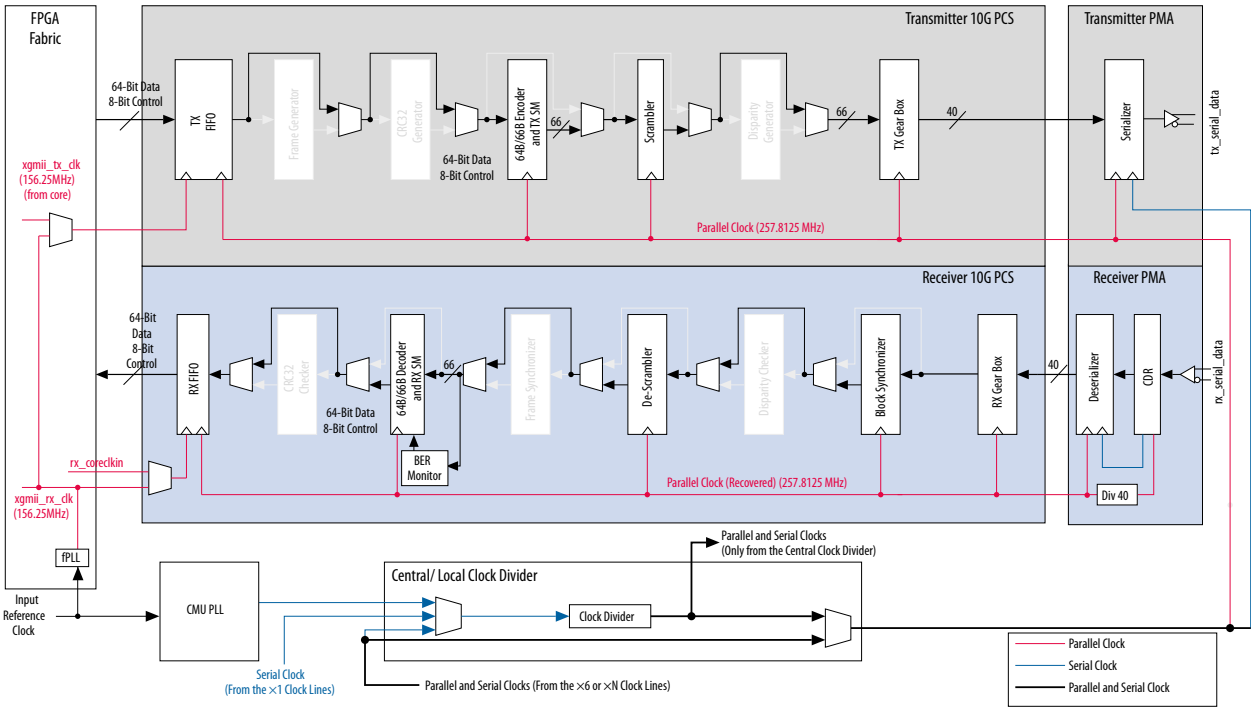

10GBASE-KR

Figure 6-5: 10GBASE-R/KR and 1000Base-X/KX Datapath Configuration

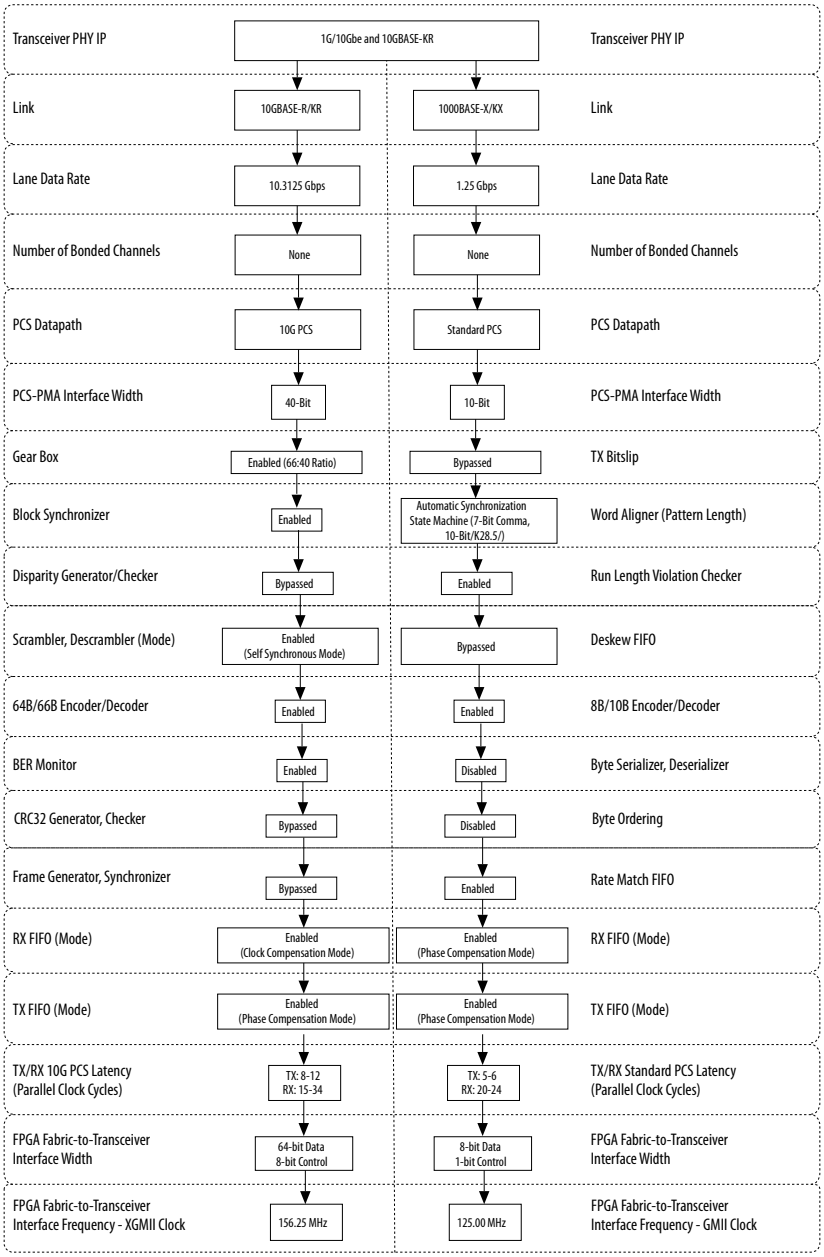

Figure 6-6: Transceiver Channel Datapath for 10GBASE-R/KR and 1000BASE-X/KX Configuration

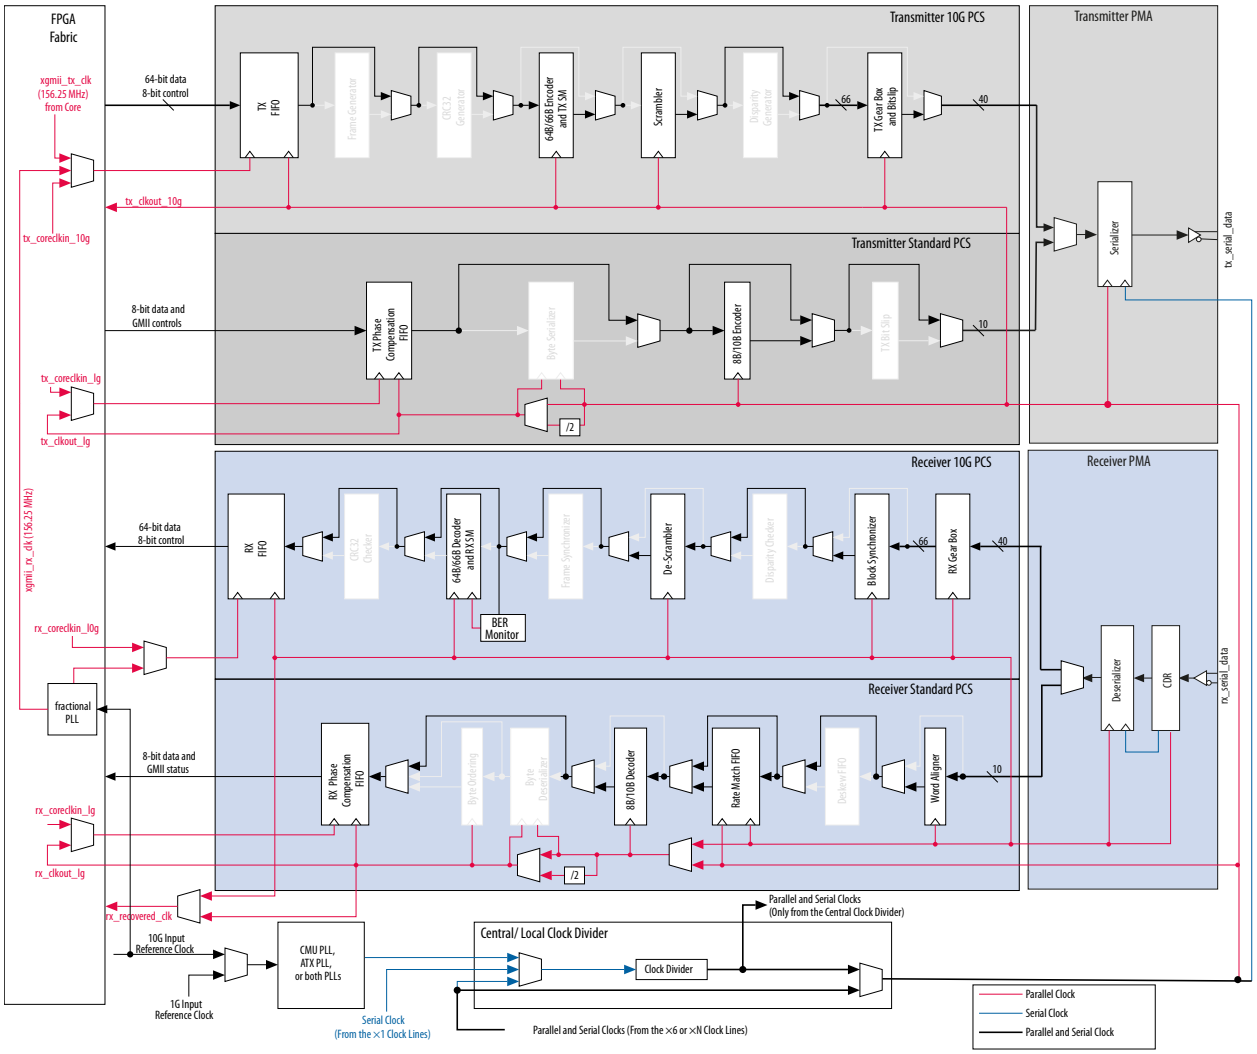


10GBASE-R and 10GBASE-KR Supported Features

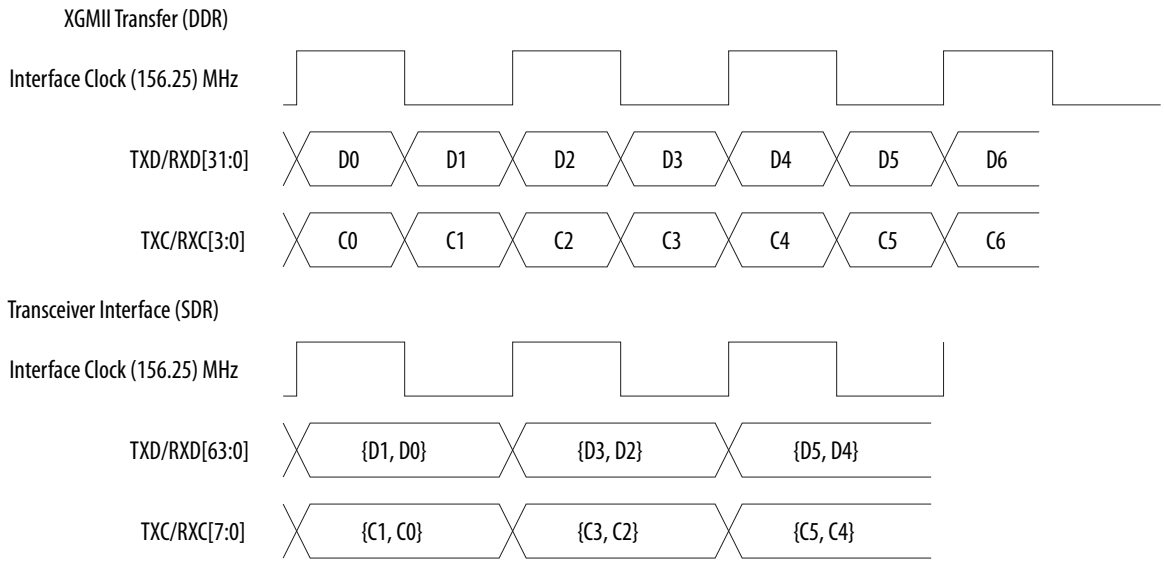
The following features are supported by the transceivers in 10GBASE-R and 10GBASE-KR configurations.

64-Bit Single Data Rate (SDR) Interface to the MAC/RS in 10GBASE-R and 10GBASE-KR Configurations

Clause 46 of the IEEE 802.3-2008 specification defines the XGMII interface between the 10GBASE-R and 10GBASE-KR PCS and the Ethernet MAC/RS. The XGMII interface defines the 32-bit data and 4-bit wide control character clocked between the MAC/RS and the PCS at both the positive and negative edge (double data rate – DDR) of the 156.25 MHz interface clock.

The transceivers do not support the XGMII interface to the MAC/RS as defined in the IEEE 802.3-2008 specification. Instead, they support a 64-bit data and 8-bit control SDR interface between the MAC/RS and the PCS.

Figure 6-7: XGMII Interface (DDR) versus Arria V GZ Transceiver Interface (SDR) for 10GBASE-R and 10GBASE-KR Configurations



64B/66B Encoding/Decoding in 10GBASE-R and 10GBASE-KR Configurations

The transceivers in 10GBASE-R and 10GBASE-KR configurations support 64B/66B encoding and decoding as specified in Clause 49 of the IEEE802.3-2008 specification. The 64B/66B encoder receives 64-bit data and 8-bit control code from the transmitter FIFO and converts it into 66-bit encoded data. The 66-bit encoded data contains two overhead sync header bits that the receiver PCS uses for block synchronization and bit-error rate (BER) monitoring.

The 64B/66B encoding also ensures enough transitions on the serial data stream for the receiver clock data recovery (CDR) to maintain its lock on the incoming data.

Transmitter and Receiver State Machines in 10GBASE-R and 10GBASE-KR Configurations

The transceivers in 10GBASE-R and 10GBASE-KR configurations implement the transmitter and receiver state diagrams shown in Figure 49-14 and Figure 49-15 of the IEEE802.3-2008 specification.

Besides encoding the raw data specified in the 10GBASE-R and 10GBASE-KR PCS, the transmitter state diagram performs functions such as transmitting local faults (LBLOCK_T) under reset, as well as transmitting error codes (EBLOCK_T) when the 10GBASE-R PCS rules are violated.

Besides decoding the incoming data specified in the 10GBASE-R and 10GBASE-KR PCS, the receiver state diagram performs functions such as sending local faults (LBLOCK_R) to the MAC/RS under reset and substituting error codes (EBLOCK_R) when the 10GBASE-R and 10GBASE-KR PCS rules are violated.

Block Synchronizer in 10GBASE-R and 10GBASE-KR Configurations

The block synchronizer in the receiver PCS determines when the receiver has obtained lock to the received data stream. It implements the lock state diagram shown in Figure 49-12 of the IEEE 802.3-2008 specification.

The block synchronizer provides a status signal to indicate whether it has achieved block synchronization or not.

Self-Synchronous Scrambling/Descrambling in 10GBASE-R and 10GBASE-KR Configurations

The scrambler/descrambler blocks in the transmitter/receiver PCS implements the self-synchronizing scrambler/descrambler polynomial 1 + x39 + x58, as described in clause 49 of the IEEE 802.3-2008 specification. The scrambler/descrambler blocks are self-synchronizing and do not require an initialization seed. Barring the two sync header bits in each 66-bit data block, the entire payload is scrambled or descrambled.

BER Monitor in 10GBASE-R and 10GBASE-KR Configurations

The BER monitor block in the receiver PCS implements the BER monitor state diagram shown in Figure 49-13 of the IEEE 802.3-2008 specification. The BER monitor provides a status signal to the MAC whenever the link BER threshold is violated.

The 10GBASE-R core and the 1G/10GbE and 10GBASE-KR PHY IP core (10GBASE-KR mode) provide a status flag to indicate a high BER whenever 16 synchronization header errors are received within a 125 µs window.

Clock Compensation in 10GBASE-R and 10GBASE-KR Configurations

The receiver FIFO in the receiver PCS datapath compensates up to ±100 ppm difference between the remote transmitter and the local receiver. The receiver FIFO does so by inserting Idles (/I/) and deleting Idles (/I/) or Ordered Sets (/O/), depending on the ppm difference.

- **Idle Insertion** — The receiver FIFO inserts eight /I/ codes following an /I/ or /O/ to compensate for clock rate disparity.
- **Idle (/I/) or Sequence Ordered Set (/O/) Deletion** — The receiver FIFO deletes either four /I/ codes or ordered sets (/O/) to compensate for the clock rate disparity. The receiver FIFO implements the following IEEE802.3-2008 deletion rules:
  - Deletes the lower four /I/ codes of the current word when the upper four bytes of the current word do not contain a Terminate /T/ control character.
  - Deletes one /O/ ordered set only when the receiver FIFO receives two consecutive /O/ ordered sets.

10GBASE-KR and 1000BASE-KX Link Training

The Link Training function defined in clause 72 of IEEE 802.3ap-2007 specification is implemented in the core fabric. The 1G/10GbE and 10GBASE-KR PHY IP Link Training logic includes the Training Frame Generator, Training Frame Synchronizer, PRBS11 generator, control channel codec, Local Device (LD) transceiver transmit PMA pre-emphasis coefficient status reporting, the Link Partner (LP) transmit PMA pre-emphasis coefficient update request, and the receiver link training status.

Arria V GZ channels employ three PMA transmit driver pre-emphasis taps: pre-tap, main tap, and first post-tap as required and defined by clause 72, Section 72.7.1.10 Transmitter output waveform for 10GBASE-KR PHY operation. The pre-emphasis coefficients is dynamically adjusted by the PHY IP during the Link Training process.

10GBASE-KR and 1000BASE-KX Auto-Negotiation

The Auto-Negotiation function defined in clause 73 of IEEE 802.3ap-2007 specification must be implemented in the core fabric. The 1G/10GbE and 10GBASE-KR PHY IP Auto-Negotiation logic includes the Differential Manchester Encoding (DME) page codec, AN page lock and synchronizer, and the Transmit, Receive, and Arbitration logic state machines.

10GBASE-KR Forward Error Correction

The FEC function defined in clause 74 of IEEE 802.3ap-2007 specification must be implemented in the core fabric. In Arria V GZ devices, the hard PCS does not support applications that require FEC function-

ality. To implement a 10GBASE-KR link with FEC support, the entire PCS functionality and the FEC logic must be implemented in the core fabric and the transceiver configured in Low Latency Configuration using the Native PHY IP.

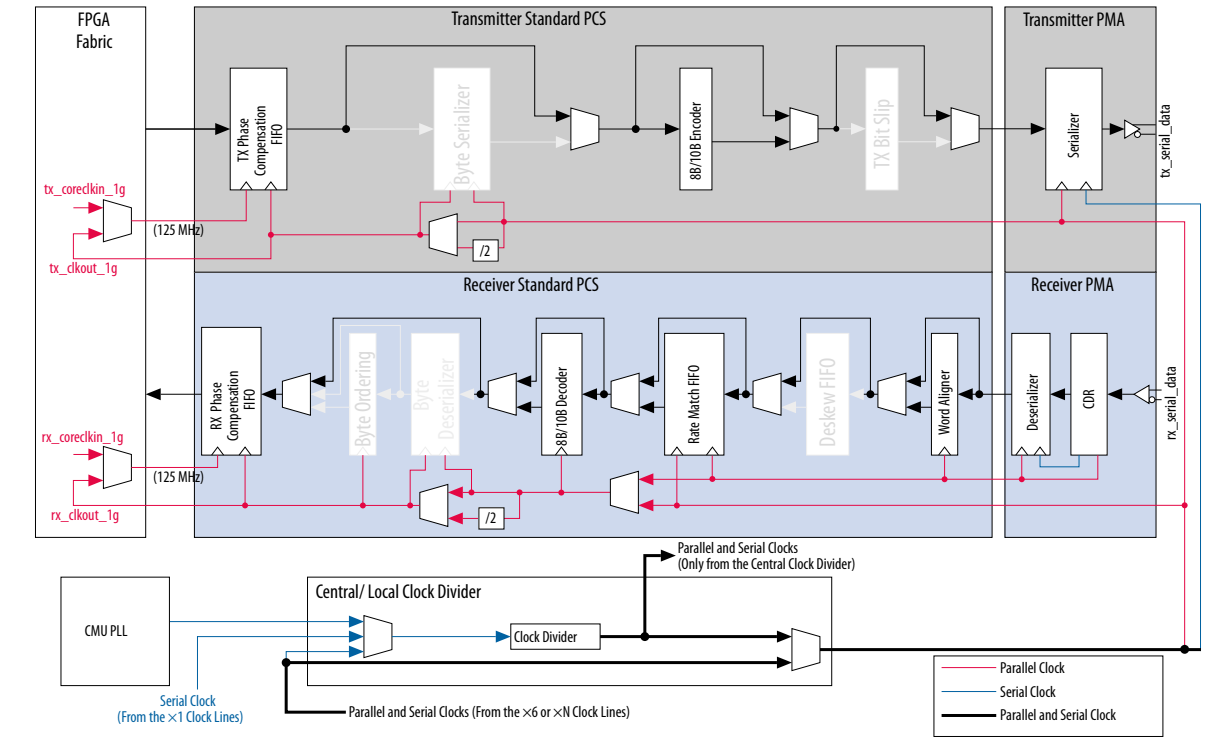
1000BASE-X and 1000BASE-KX Transceiver Datapath

The following figure shows the transceiver datapath and clock frequencies in 1000BASE-X and 1000BASE-KX configurations.

Figure 6-8: 1000BASE-X and 1000BASE-KX Datapath Configurations



1000BASE-X and 1000BASE-KX Supported Features

The following features are supported by the transceivers in 1000BASE-X and 1000BASE-KX configurations.

8B/10B Encoder in 1000BASE-X and 1000BASE-KX Configurations

In 1000BASE-X and 1000BASE-KX modes, the 8B/10B encoder clocks in 8-bit data and 1-bit control identifiers from the transmitter phase compensation FIFO and generates 10-bit encoded data. The 10-bit encoded data is fed to the serializer.

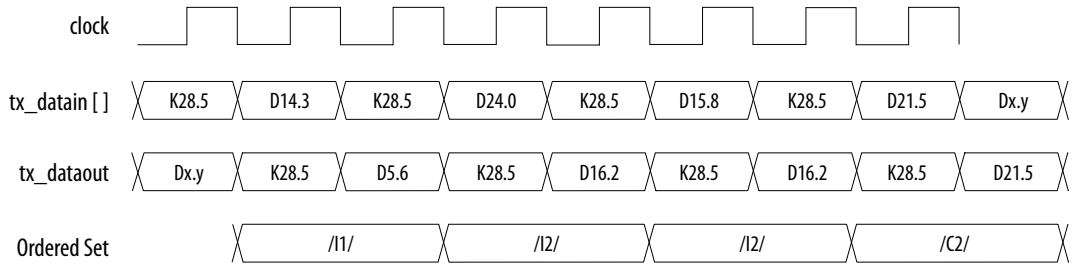
Idle Ordered-Set Generation in 1000BASE-X and 1000BASE-KX Configurations

The IEEE 802.3 specification requires the 1000BASE-X and 1000BASE-KX PHY to transmit idle ordered sets (/I/) continuously and repetitively whenever the GMII is idle. This ensures that the receiver maintains bit and word synchronization whenever there is no active data to be transmitted.

In 1000BASE-X and 1000BASE-KX functional modes, any /Dx.y/ following a /K28.5/ comma is replaced by the transmitter with either a /D5.6/ (/I1/ ordered set) or a /D16.2/ (/I2/ ordered set), depending on the current running disparity. The exception is when the data following the /K28.5/ is /D21.5/ (/C1/ ordered set) or /D2.2/ (/C2/) ordered set. If the running disparity before the /K28.5/ is positive, an /I1/ ordered set is generated. If the running disparity is negative, a /I2/ ordered set is generated. The disparity at the end of a /I1/ is the opposite of that at the beginning of the /I1/. The disparity at the end of a /I2/ is the same as the beginning running disparity (right before the idle code). This ensures a negative running disparity at the end of an idle ordered set. A /Kx.y/ following a /K28.5/ is not replaced.

Note: /D14.3/, /D24.0/, and /D15.8/ are replaced by /D5.6/ or /D16.2/ (for /I1/, /I2/ ordered sets). /D21.5/ (part of the /C1/ order set) is not replaced.

Figure 6-9: Example of Automatic Ordered Set Generation



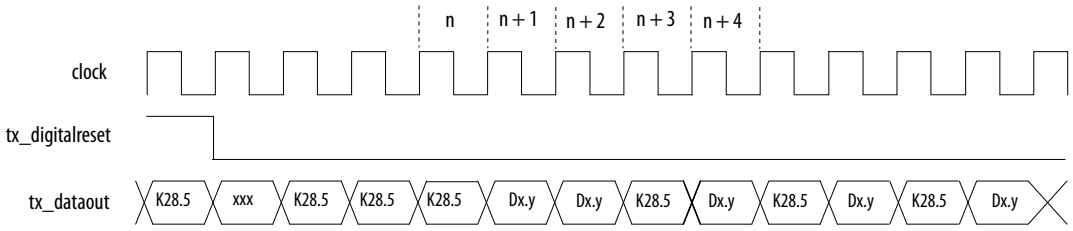
Reset Condition in 1000BASE-X and 1000BASE-KX Configurations

After deassertion of `tx_digitalreset`, the 1000BASE-X and 1000BASE-KX transmitters automatically transmit three /K28.5/ comma code groups before transmitting user data on the `tx_datain` port. This could affect the synchronization state machine behavior at the receiver.

Depending on when you start transmitting the synchronization sequence, there could be an even or odd number of /Dx.y/ code groups transmitted between the last of the three automatically sent /K28.5/ code groups and the first /K28.5/ code group of the synchronization sequence. If there is an even number of /Dx.y/ code groups received between these two /K28.5/ code groups, the first /K28.5/ code group of the synchronization sequence begins at an odd code group boundary (`rx_even` = FALSE). An IEEE802.3-compliant 1000BASE-X or 1000BASE-KX synchronization state machine treats this as an error condition and goes into the loss of sync state.

The following figure shows an example of even numbers of /Dx.y/ between the last automatically sent /K28.5/ and the first user-sent /K28.5/. The first user-sent /K28.5/ code group received at an odd code group boundary in cycle n + 3 takes the receiver synchronization state machine in the loss of sync state. The first synchronization ordered set /K28.5/Dx.y/ in cycles n + 3 and n + 4 is discounted and three additional ordered sets are required for successful synchronization.

Figure 6-10: Example of Reset Condition in 1000BASE-X and 1000BASE-KX Configurations



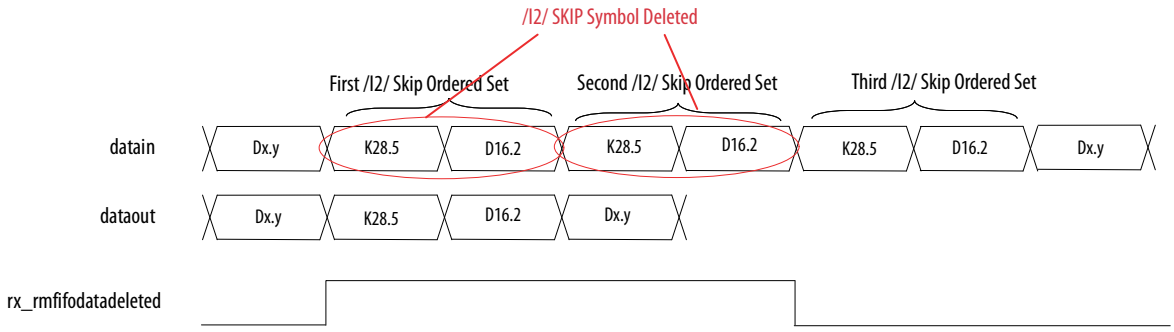
Rate Match FIFO in 1000BASE-X and 1000BASE-KX Configurations

In 1000BASE-X and 1000BASE-KX modes, the rate match FIFO is capable of compensating for up to ±100 ppm (200 ppm total) difference between the upstream transmitter and the local receiver reference clock. The 1000BASE-X and 1000BASE-KX protocols require the transmitter to send idle ordered sets /I1/ (/K28.5/D5.6/) and /I2/ (/K28.5/D16.2/) during inter-packet gaps adhering to the rules listed in the IEEE 802.3 specification.

The rate match operation begins after the synchronization state machine in the word aligner indicates synchronization is acquired by driving the `rx_syncstatus` signal high. The rate matcher deletes or inserts both symbols (/K28.5/ and /D16.2/) of the /I2/ ordered sets even if it requires deleting only one symbol to prevent the rate match FIFO from overflowing or under-running. It can insert or delete as many /I2/ ordered sets as necessary to perform the rate match operation.

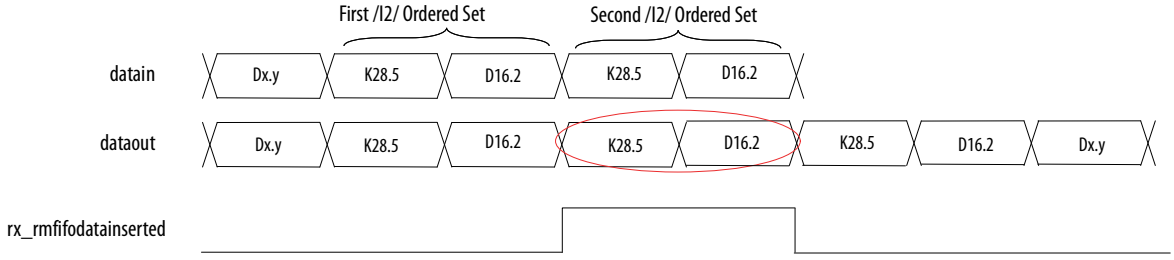
The following figure shows an example of rate match FIFO deletion where three symbols are required to be deleted. Because the rate match FIFO can only delete /I2/ ordered set, it deletes two /I2/ ordered sets (four symbols deleted).

Figure 6-11: Example of Rate Match Deletion in 1000BASE-X and 1000BASE-KX Configurations



The following figure shows an example of rate match FIFO insertion in the case where one symbol is required to be inserted. Because the rate match FIFO can only delete /I2/ ordered set, it inserts one /I2/ ordered set (two symbols inserted).

Figure 6-12: Example Rate Match Insertion in 1000BASE-X and 1000BASE-KX Configurations



Two register bits, `rx_rmfifodatadeleted` and `rx_rmfifodatainserted`, indicate rate match FIFO deletion and insertion events. Both the `rx_rmfifodatadeleted` and `rx_rmfifodatainserted` status flags are latched High during deleted and inserted /I2/ ordered sets.

Note: If you have the autonegotiation state machine in the FPGA, note that the rate match FIFO is capable of inserting or deleting the first two bytes (/K28.5//D2.2/) of /C2/ ordered sets during autonegotiation. However, the insertion or deletion of the first two bytes of /C2/ ordered sets can cause the autonegotiation link to fail. For more information, refer to the **Altera Knowledge Base Support Solution**.

Word Aligner in 1000BASE-X and 1000BASE-KX Configurations

The word aligner in 1000BASE-X and 1000BASE-KX functional modes is configured in automatic synchronization state machine mode. The Quartus II software automatically configures the synchronization state machine to indicate synchronization when the receiver receives three consecutive synchronization ordered sets. A synchronization ordered set is a /K28.5/ code group followed by an odd number of valid /Dx.y/ code groups. The fastest way for the receiver to achieve synchronization is to receive three continuous {/K28.5/, /Dx.y/} ordered sets.

Receiver synchronization is indicated on the `rx_syncstatus` port of each channel. A high on the `rx_syncstatus` port indicates that the lane is synchronized; a low on the `rx_syncstatus` port indicates that the lane has fallen out of synchronization. The receiver loses synchronization when it detects four invalid code groups separated by less than three valid code groups or when it is reset.

Synchronization State Machine Parameters in 1000BASE-X and 1000BASE-KX Configurations

Table 6-1: Synchronization State Machine Parameters in 1000BASE-X or 1000BASE-KX Mode

Synchronization State Machine Parameters	Settings
Number of valid {/K28.5/, /Dx,y/} ordered sets received to achieve synchronization	3
Number of errors received to lose synchronization	4
Number of continuous good code groups received to reduce the error count by 1	4

Transceiver Clocking in 10GBASE-R, 10GBASE-KR, 1000BASE-X, and 1000BASE-KX Configurations

The CMU PLL or the auxiliary transmit (ATX) PLLs in a transceiver bank generate the transmitter serial and the fractional PLL for the parallel clocks for the 10GBASE-R, 10GBASE-KR, 1000BASE-X, and 1000BASE-KX channels. The following table lists the configuration details.

Table 6-2: Input Reference Clock Frequency and Interface Speed Specifications for 10GBASE-R, 10GBASE-KR, and 1000BASE-KX Configurations

PHY IP Type	PHY Type	Input Reference Clock Frequency (MHz)	FPGA Fabric-Transceiver Interface Width	FPGA Fabric-Transceiver Interface Frequency (MHz)
10GBASE-R PHY IP	10GBASE-R	644.53125, 322.265625	64-bit data, 8-bit control	156.25
1G/10GbE and 10GBASE-KR PHY IP	10GBASE-R and 10GBASE-KR	644.53125, 322.265625	64-bit data, 8-bit control	156.25
1G/10GbE and 10GBASE-KR PHY IP	1000BASE-X and 1000BASE-KX	125, 62.5	8-bit data, `gmii_tx_en` and `gmii_tx_err` control	125

Interlaken

Interlaken is a scalable, chip-to-chip interconnect protocol that enables transmission speeds from 10 to more than 100 Gbps.

Arria V GZ devices support a transmission speed of up to 12.5 Gbps per lane in an Interlaken configuration. All the PCS blocks in the Interlaken configuration conform to the Interlaken Protocol Definition, Rev 1.2.

To implement an Interlaken link, instantiate the **Interlaken PHY IP** core in the IP Catalog, under **Interlaken** in the Interfaces menu.

Related Information

Refer to the Interlaken PHY IP Core chapter in the Altera Transceiver PHY IP Core User Guide

Transceiver Datapath Configuration

Figure 6-13: Interlaken Datapath Configuration

Blocks shown as “Disabled” are not used but incur latency. Blocks shown as “Bypassed” are not used and do not incur any latency. The maximum data rates and frequencies are for the fastest speed grade devices.

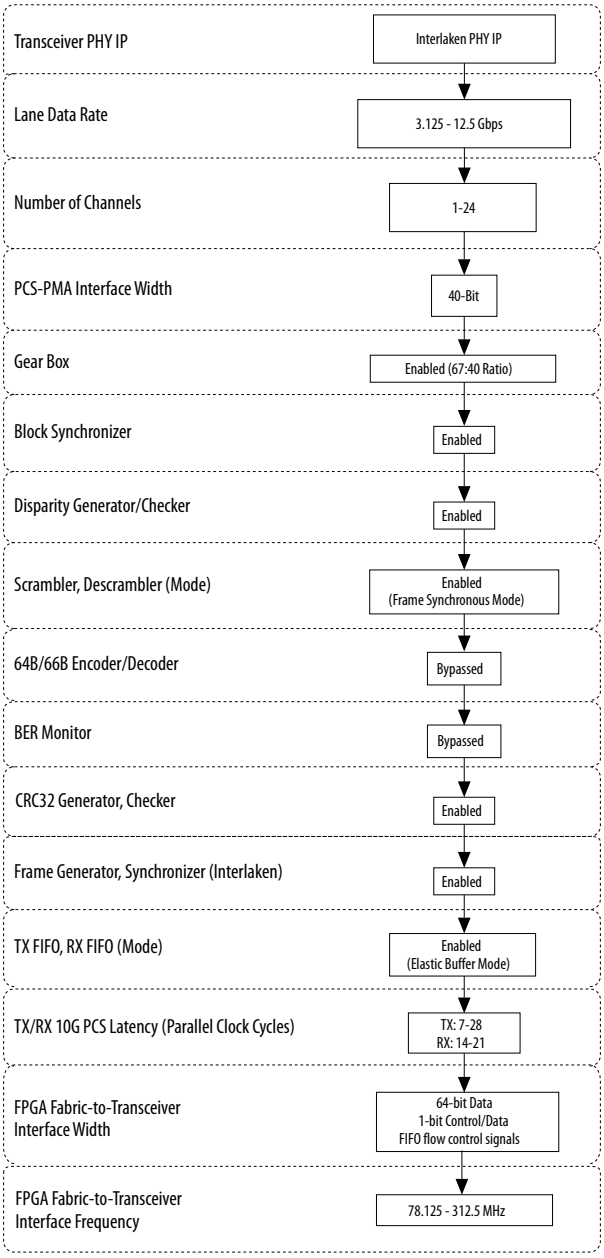


Figure 6-14: Transceiver Channel Datapath for Interlaken Configuration

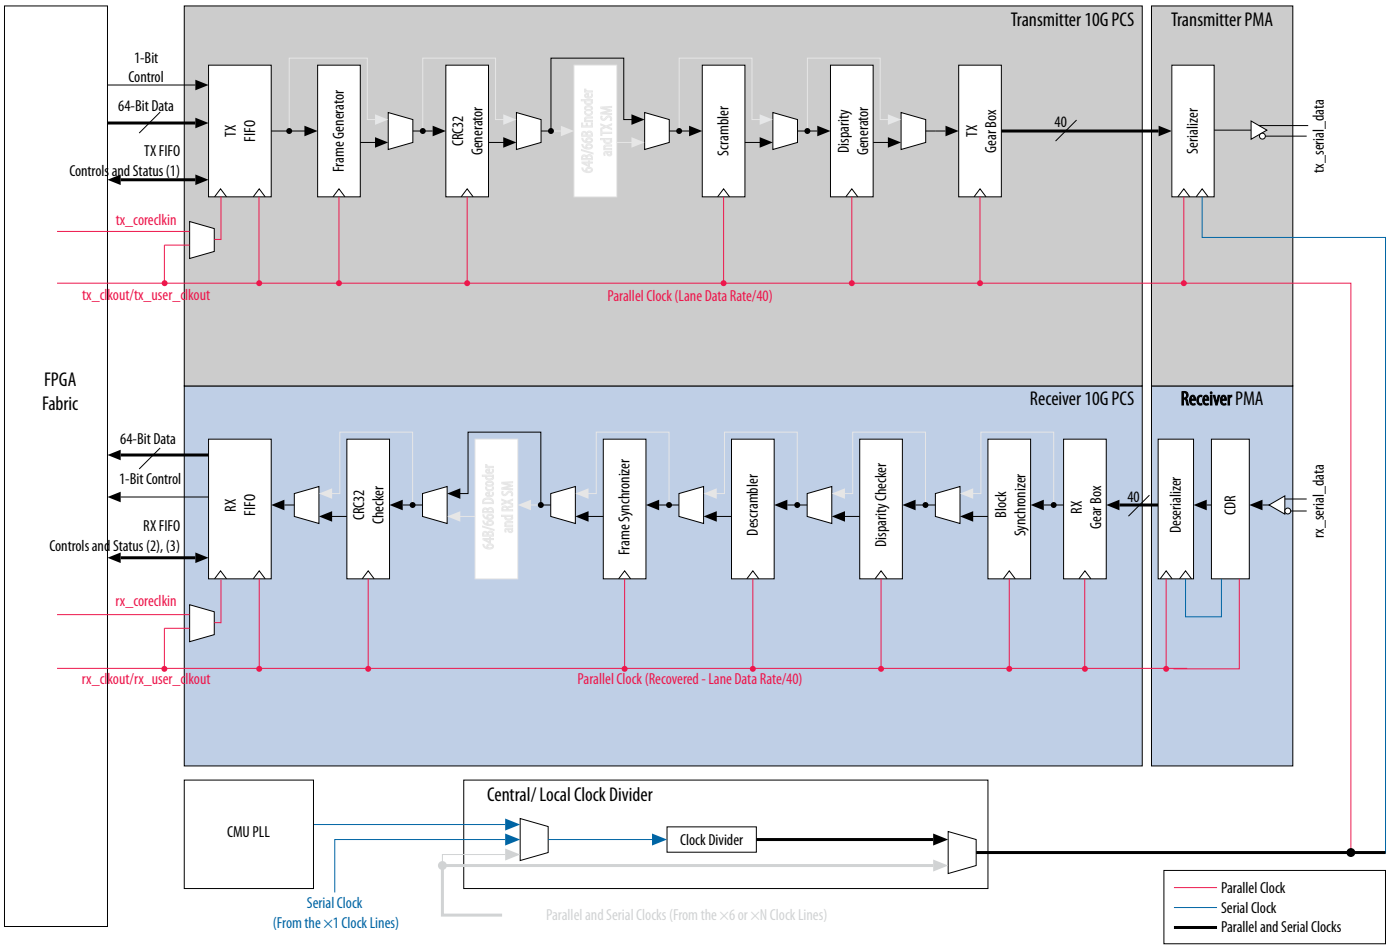


Notes:
(1) TX FIFO Control and Status (transmit backpressure and datavalid, synchronization done)
(2) RX FIFO Control (receive FIFO read enable and datavalid)
(3) RX FIFO Status (receive FIFO overflow and partially empty)

Supported Features

The Interlaken protocol supports a number of framing layer functions. The functions are defined in the Interlaken Protocol Definition, Rev 1.2.

Table 6-3: Supported Features in Interlaken Configuration

Feature	Supported
Metaframe generation and payload insertion	Yes
Block synchronization (word alignment) and metaframe synchronization (frame synchronization)	Yes
64B/67B framing	Yes
±96 bits disparity maintenance	Yes
Frame synchronous scrambling and descrambling	Yes

Feature	Supported
Diagnostic word generation	Yes
Framing Layer Control Word Forwarding	Yes
CRC-32 generation and checking of lane data integrity	Yes
Multi-lane deskew alignment	No
Transmit and receive FIFO backpressure control and handshake	Yes

Block Synchronizer

The block synchronizer in the receiver PCS achieves and maintains a 64B/67B word boundary lock. This block searches for valid synchronization header bits within the data stream and achieves lock after 64 consecutive legal synchronization patterns are found. After a 64B/67B word boundary lock is achieved, the block synchronizer continuously monitors and flags for invalid synchronization header bits. If 16 or more invalid synchronization header bits are found within 64 consecutive word boundaries, the block synchronizer deasserts the lock state and searches again for valid synchronization header bits.

The block synchronizer implements the flow diagram shown in Figure 13 of Interlaken Protocol Definition v1.2 and provides the word lock status to the FPGA fabric.

64B/67B Frame Generator

The transmit frame generator implements 64B/67B encoding, as explained in Interlaken Protocol Definition v1.2. The Interlaken metaframe generator synchronously generates the framing layer control words, frame synchronizer, scrambler state, skip words, and diagnostic word, and maps the transmitter data into the payload of the metaframes. The metaframe length is programmable from 5 to a maximum value of 8191, 8-byte words.

Note: Ensure that the metaframe length is programmed to the same value for both the transmitter and receiver.

Frame Synchronizer

The receive frame synchronizer delineates the metaframe boundaries and searches for each of the framing layer control words: Synchronization, Scrambler State, Skip, and Diagnostic. When four consecutive synchronization words have been identified, the frame synchronizer achieves the frame locked state. Subsequent metaframes are then checked for valid synchronization and scrambler state words. If four consecutive invalid synchronization words or three consecutive mismatched scrambler state words are received, the frame synchronizer loses frame lock. In addition, the frame synchronizer provides a receiver metaframe lock status to the FPGA fabric.

Running Disparity

The disparity generator inverts the sense of bits in each transmitted word to maintain a running disparity of ± 96 bit boundary. It supplies a framing bit in bit position 66 as explained in Table 4 of Interlaken Protocol Definition Revision 1.2. The framing bit enables the disparity checker to identify whether bits[63:0] for that word are inverted.

Frame Synchronous Scrambling/Descrambling

The scrambler/descrambler block in the transmitter/receiver PCS implements the scrambler/descrambler polynomial x58 + x39 + 1 per Interlaken Protocol Definition Revision 1.2. Synchronization and Scrambler State Words, as well as the 64B/67B framing bits are not scrambled/descrambled. The Interlaken PHY IP

core automatically programs random linear feedback shift register (LFSR) initialization seed values per lane.

The receiver PCS synchronizes the scrambler with the metaframe as described in the state flow shown in Figure 1 of Interlaken Protocol Definition Revision 1.2.

The frame synchronizer features a whole set of error and performance monitoring ports to the FPGA fabric interface and register status bits when using the Avalon® Memory-Mapped Management Interface. A receiver ready port, frame lock status, and cyclic redundancy check (CRC)-32 error detection port is available to the FPGA fabric. The Avalon Memory-Mapped Management Interface provides additional functionality with word boundary lock, frame lock status, synchronization word error detection, scrambler mismatch error, and CRC-32 error detection status register bits.

Skip Word Insertion

The frame generator generates the mandatory fixed location skip words with every metaframe following the scrambler state word and generates additional skip words based on the transmitter FIFO capacity state.

Skip Word Deletion

The frame synchronizer does not delete skip words. Instead, the frame synchronizer forwards the skip words it receives to the MAC layer so the MAC can maintain and perform deskew alignment.

Diagnostic Word Generation and Checking of Lane Data Integrity (CRC-32)

The CRC-32 generator calculates the CRC for each metaframe and appends it to the diagnostic word of the metaframe. An optional CRC-32 error flag is also provided to the FPGA fabric.

Framing Layer Control Word Forwarding

The four metaframe framing layer control words-Synchronization, Scrambler State, Skip, and Diagnostic Words-are not deleted but forwarded to the MAC layer. This action enables the MAC layer to employ multi-lane deskew alignment within the FPGA fabric.

Multi-Lane Deskew Alignment

The Interlaken PHY IP does not support multi-lane deskew alignment. You must implement the multi-lane deskew alignment state machine in the core fabric or the Altera Interlaken MegaCore® function within the FPGA fabric.

Transmit and Receive FIFO Control and Status

The Interlaken PCS configures the transmit and receive FIFOs in elastic buffer mode. In this mode of operation, a lane synchronization, backpressure and FIFO control, and status port signals are provided to the MAC layer for handshaking.

Transceiver Multi-Lane Bonding and Transmit Skew

A soft-bonding IP is used for Interlaken bonding in the transceivers. The transceiver clocking in each lane is configured as non-bonded. For multi-lane designs, a dedicated PLL reference clock pin that is equidistant from the transmit PLLs in each bank must be selected. You must tightly match lane board traces to minimize lane-to-lane skew.

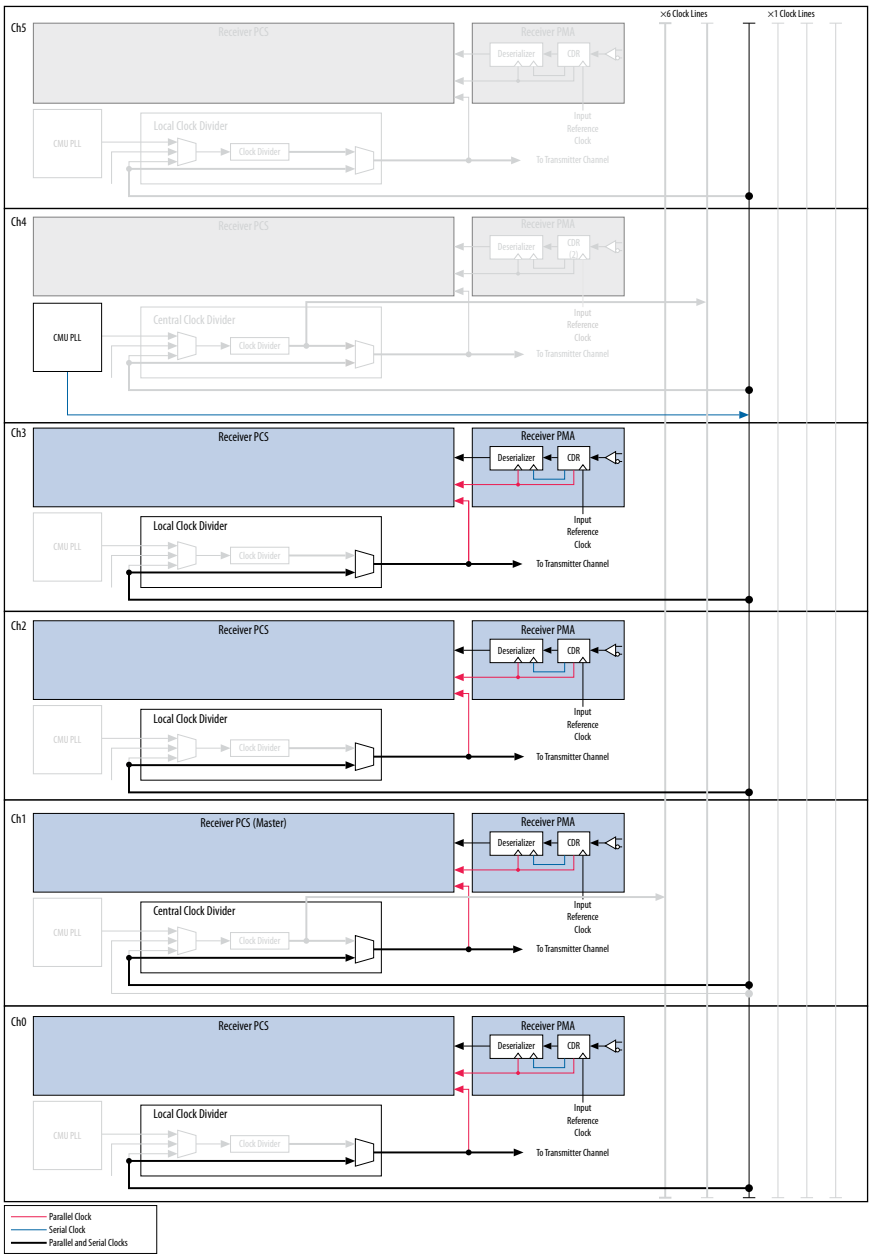
Related Information

- **For more information about Interlaken PHY IP control and status signals associated with each feature, refer to the Interlaken PHY IP Core chapter in the Altera Transceiver PHY IP Core User Guide**
- **Interlaken MegaCore Function User Guide**

Transceiver Clocking

Describes the transceiver clocking for the Interlaken protocol.

Figure 6-15: Clocking Resources Available in a Four-Lane Interlaken Configuration



A CMU PLL may provide a clock for up to five Interlaken lanes within a transceiver bank. If an ATX PLL is used, the PLL can clock up to six Interlaken lanes in a transceiver bank.

Note: To enable the ATX PLL, you must select **ATX PLL** for the **PLL type** parameter in the Interlaken PHY IP.

PCI Express (PCIe)—Gen1, Gen2, and Gen3

The PCIe specification (version 3.0) provides implementation details for a PCIe-compliant physical layer device at Gen1 (2.5 Gbps), Gen2 (5 Gbps), and Gen3 (8 Gbps) signaling rates.

The devices have built-in PCIe hard IP blocks to implement the PHY MAC layer, data link layer, and transaction layer of the PCIe protocol stack. Up to four PCIe hard IP block reside within an Arria V GZ device. If you enable the PCIe hard IP block, the transceiver interfaces with the hard IP block. Otherwise, the transceiver interfaces directly through the PIPE interface. You must then implement a Soft-IP MAC layer, data link layer, and transaction layer to the PIPE interface from the core fabric.

You can configure the transceivers in a PCIe functional configuration using one of the following methods:

- Arria V GZ Hard IP for PCI Express
- PHY IP core for PCI Express (PIPE)

The following table shows the two methods supported by transceivers in a PCIe functional configuration.

Table 6-4: Support for Transceivers

Support	Arria V GZ Hard IP for PCI Express	PHY IP Core for PCI Express (PIPE)
Gen1, Gen2, and Gen3 data rates	Yes	Yes
MAC, data link, and transaction layer	Yes	—
Transceiver interface	Hard IP through PIPE 3.0-like	PIPE 2.0 for Gen1 and Gen2 PIPE 3.0-like for Gen3 with Gen1/Gen2 support

To implement the PHY IP Core for PCI Express (PIPE) configuration, instantiate the **PHY IP Core for PCI Express (PIPE)** in the IP Catalog, under **PCI Express** in the Interfaces menu.

Arria V GZ transceivers support x1, x2, x4, and x8 lane configurations. In a PCIe x1 configuration, the PCS and PMA blocks of each channel are clocked and reset independently. PCIe x2, x4, and x8 configurations support channel bonding for two-lane, four-lane, and eight-lane PCIe links. In these bonded channel configurations, the PCS and PMA blocks of all bonded channels share common clock and reset signals.

Transceiver Datapath Configuration

The transceiver datapaths for PCI Express are different depending on whether or not Gen3 is enabled.

Figure 6-16: PCIe Gen1 and Gen2 PIPE Datapath Configuration

This transceiver datapath configuration is for a configuration without Gen3 enabled.

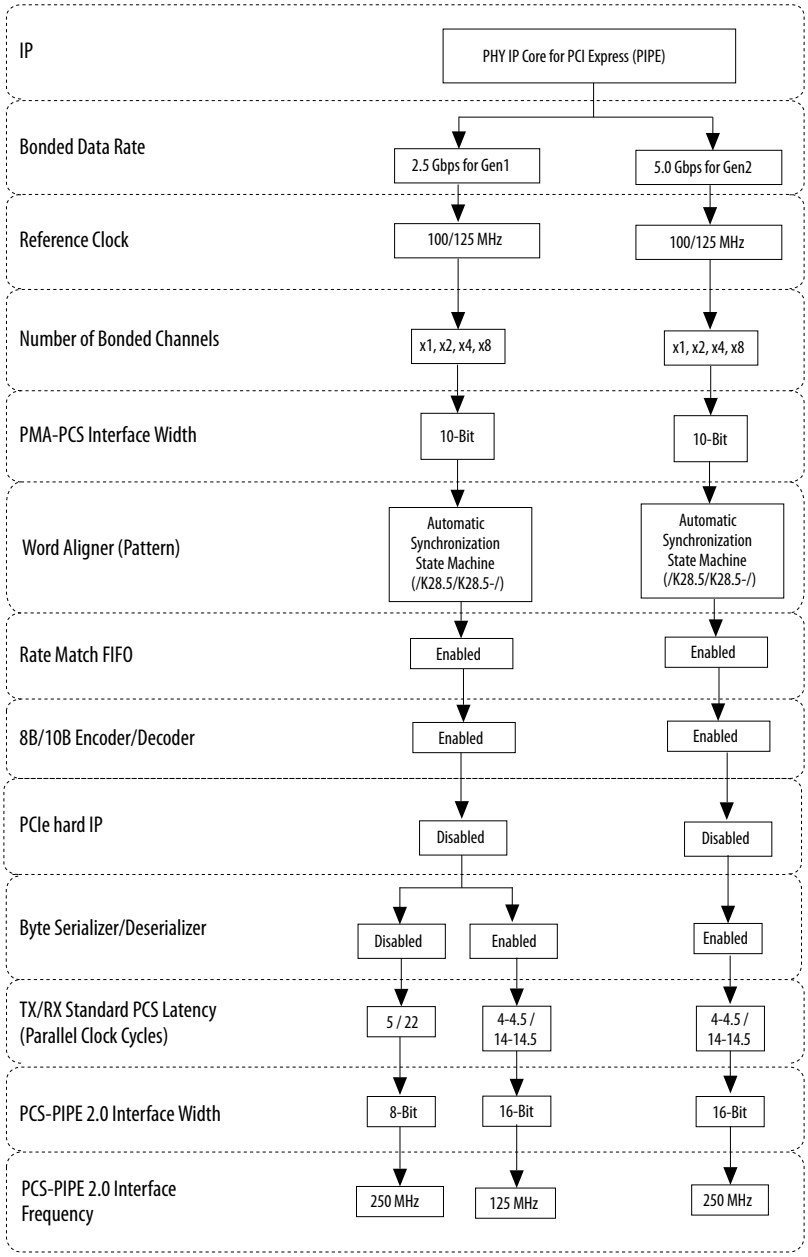

Figure 6-17: PCIe Gen1, Gen2, and Gen3 Hard IP and PHY IP Core for PCI Express Datapath Configuration

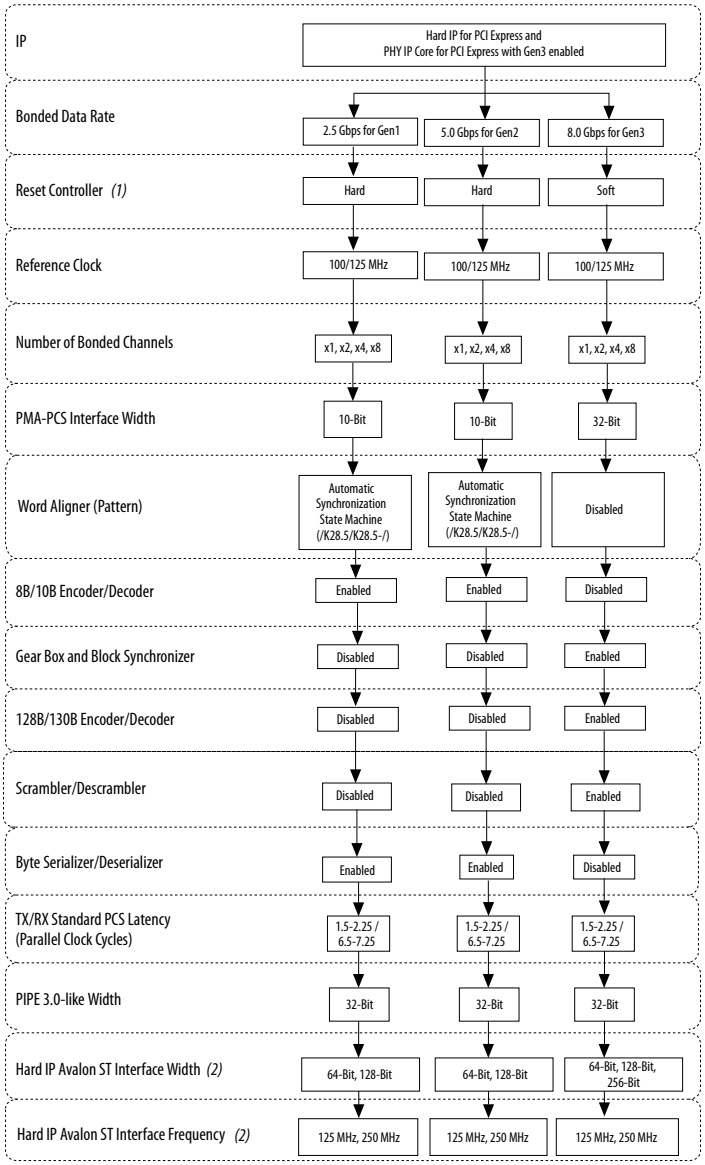
This transceiver datapath configuration is for a configuration with Gen3 enabled.

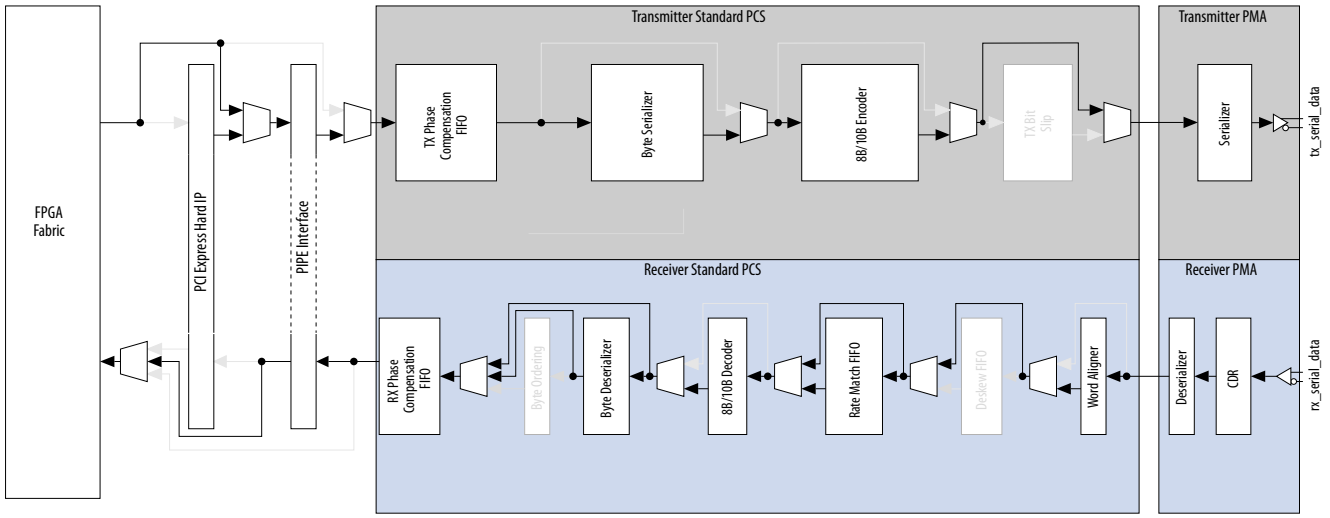


Notes:
(1) The PHY IP Core for PCI Express (PIPE configuration) employs the Embedded Reset Controller IP. It does not use the Hard or Soft Reset Controller employed in the Hard IP for PCI Express (HIP configuration).
(2) Does not apply to PHY IP Core for PCI Express configuration. Applies only to Hard IP for PCI Express configuration.

Transceiver Channel Datapath

The following figure shows the Arria V GZ transmitter and receiver channel datapath for PCIe Gen1/Gen2 configurations when using PIPE configuration with Gen3 disabled. In this configuration, the transceiver connects to a PIPE 2.0 compliant interface.

Figure 6-18: Transceiver Channel Datapath for PCIe Gen1/Gen2 in PIPE Configuration with Gen3 Disabled



The following figure shows the Arria V GZ transmitter and receiver channel datapath for PCIe Gen1/Gen2/Gen3 configurations with a 32-bit PIPE 3.0-like interface and PCI Express Base Specification Version 3.0 is enabled.

Figure 6-19: Transceiver Channel Datapath for PCIe Gen1/Gen2/Gen3 Configurations

Transceiver Architecture in Arria V Devices

Supported Features for PCIe Configurations

The features supported for a PCIe configuration are different for the 2.5 Gbps, 5 Gbps, and 8 Gbps data rate configurations.

Table 6-5: Supported Features for PCIe Configurations

Feature	Gen1 (2.5 Gbps)	Gen2 (5 Gbps)	Gen3 (8 Gbps)
x1, x2, x4, x8 link configurations	Yes	Yes	Yes
PCIe-compliant synchronization state machine	Yes	Yes	Yes
±300 ppm (total 600 ppm) clock rate compensation	Yes	Yes	Yes
8-bit FPGA fabric-transceiver interface (PIPE 2.0)	Yes	—	—
16-bit FPGA fabric-transceiver interface (PIPE 2.0)	Yes	Yes	—
32-bit FPGA fabric-transceiver interface (PIPE 3.0-like)	—	—	Yes
64-bit Hard IP Avalon-ST interface width (Hard IP only)	Yes	Yes	Yes
128-bit Hard IP Avalon-ST interface width (Hard IP only)	Yes	Yes	Yes
256-bit Hard IP Avalon-ST interface width (Hard IP only)	—	Yes	Yes
Transmitter driver electrical idle	Yes	Yes	Yes
Receiver Detection	Yes	Yes	Yes
8B/10B encoder/decoder disparity control	Yes	Yes	—
128B/130B encoder/decoder	—	—	Yes
Power state management	Yes	Yes	Yes
Receiver PIPE status encoding (pipe_rxstatus[2:0])	Yes	Yes	Yes
Dynamic switching between 2.5 Gbps and 5 Gbps signaling rate	—	Yes	—
Dynamic switching between 2.5 Gbps, 5 Gbps, and 8 Gbps signaling rate	—	—	Yes
Dynamic transmitter margining for differential output voltage control	—	Yes	Yes
Dynamic transmitter buffer de-emphasis of -3.5 dB and -6 dB	—	Yes	Yes
Dynamic Gen3 transceiver pre-emphasis, de-emphasis, and equalization	—	—	Yes

PIPE 2.0 Interface

In a PCIe PIPE configuration, each channel has a PIPE interface block that transfers data, control, and status signals between the PHY-MAC layer and the transceiver channel PCS and PMA blocks. The PIPE

configuration complies with the PIPE 2.0 specification. If you use a PIPE configuration, you must implement the PHY-MAC layer using soft IP in the FPGA fabric.

Besides transferring data, control, and status signals between the PHY-MAC layer and the transceiver, the PIPE interface block implements the following functions required in a PCIe-compliant physical layer device:

- Forcing the transmitter driver into the electrical idle state
- Initiating the receiver detect sequence
- Controlling the 8B/10B encoder/decoder
- Controlling the 128B/130B encoder/decoder
- Managing the PCIe power states
- Indicating the completion of various PHY functions
- Encoding the receiver status and error conditions on the `pipe_rxstatus[2:0]` signal, conforming to the PCIe PIPE 3.0 specification

Transceiver datapath clocking varies between non-bonded (x1) and bonded (x2, x4, and x8) configurations.

Dynamic Switching Between Gen1 (2.5 Gbps) and Gen2 (5 Gbps) Signal Rates

In a PIPE configuration, the PIPE Parameter Editor provides an input signal (`pipe_rate`) that is functionally equivalent to the RATE signal specified in the PCIe specification. A low-to-high transition on this input signal (`pipe_rate`) initiates a data rate switch from Gen1 to Gen2. A high-to-low transition on the input signal initiates a data rate switch from Gen2 to Gen1. The signaling rate switch between Gen1 and Gen2 is achieved by changing the transceiver datapath clock frequency between 250 MHz and 500 MHz, while maintaining a constant, 16-bit width transceiver interface.

Transmitter Electrical Idle Generation

The PIPE interface block in Arria V GZ devices puts the transmitter buffer in the channel in an electrical idle state when the electrical idle input signal is asserted. During electrical idle, the transmitter buffer differential and common configuration output voltage levels are compliant to the PCIe Base Specification 2.0 for both PCIe Gen1 and Gen2 data rates.

The PCIe specification requires the transmitter driver to be in electrical idle in certain power states. For more information about input signal levels required in different power states, refer to “Power State Management”.

Power State Management

The PCIe specification defines four power states—P0, P0s, P1, and P2—that the physical layer device must support to minimize power consumption:

- P0 is the normal operating state during which packet data is transferred on the PCIe link.
- P0s, P1, and P2 are low-power states into which the physical layer must transition as directed by the PHY-MAC layer to minimize power consumption.

The PIPE interface in Arria V GZ transceivers provides an input port for each transceiver channel configured in a PIPE configuration.

Note: When transitioning from the P0 power state to lower power states (P0s, P1, and P2), the PCIe specification requires the physical layer device to implement power saving measures. Arria V GZ transceivers do not implement these power saving measures except for putting the transmitter buffer in electrical idle in the lower power states.

8B/10B Encoder Usage for Compliance Pattern Transmission Support

The PCIe transmitter transmits a compliance pattern when the Link Training and Status State Machine (LTSSM) enters the Polling.Compliance substate. The Polling.Compliance substate is used to assess if the transmitter is electrically compliant with the PCIe voltage and timing specifications.

Receiver Electrical Idle Inference

The PCIe protocol allows inferring the electrical idle condition at the receiver instead of detecting the electrical idle condition with analog circuitry.

In all PIPE configurations, (x1, x2, x4, and x8), each receiver channel PCS has an optional Electrical Idle Inference module that implements the electrical idle inference conditions specified in the PCIe Base Specification 2.0.

Receiver Status

The PCIe specification requires the PHY to encode the receiver status on a 3-bit status signal (`pipe_rxstatus[2:0]`). This status signal is used by the PHY-MAC layer for its operation. The PIPE interface block receives status signals from the transceiver channel PCS and PMA blocks, and encodes the status on the `pipe_rxstatus[2:0]` signal to the FPGA fabric. The encoding of the status signals on the `pipe_rxstatus[2:0]` signal conforms to the PCIe specification.

Receiver Detection

The PIPE interface block in Arria V GZ transceivers provides an input signal (`pipe_txdetectrx_loopback`) for the receiver detect operation required by the PCIe protocol during the Detect state of the LTSSM. When the `pipe_txdetectrx_loopback` signal is asserted in the P1 power state, the PCIe interface block sends a command signal to the transmitter driver in that channel to initiate a receiver detect sequence. In the P1 power state, the transmitter buffer must always be in the electrical idle state. After receiving this command signal, the receiver detect circuitry creates a step voltage at the output of the transmitter buffer. If an active receiver (that complies with the PCIe input impedance requirements) is present at the far end, the time constant of the step voltage on the trace is higher when compared with the time constant of the step voltage when the receiver is not present. The receiver detect circuitry monitors the time constant of the step signal seen on the trace to determine if a receiver was detected. The receiver detect circuitry requires a 125-MHz clock for operation that you must drive on the `fixedclk` port.

Note: For the receiver detect circuitry to function reliably, the transceiver on-chip termination must be used and the AC-coupling capacitor on the serial link and the receiver termination values used in your system must be compliant with the PCIe Base Specification 2.0.

The PIPE core provides a 1-bit PHY status (`pipe_phystatus`) and a 3-bit receiver status signal (`pipe_rxstatus[2:0]`) to indicate whether a receiver was detected or not, as per the PIPE 2.0 specifications.

Gen1 and Gen2 Rate Match FIFO

In compliance with the PCIe protocol, Arria V GZ receiver channels have a rate match FIFO to compensate for small clock frequency differences up to ±300 ppm between the upstream transmitter and the local receiver clocks.

PCIe Reverse Parallel Loopback

PCIe reverse parallel loopback is only available in a PCIe functional configuration for Gen1, Gen2, and Gen3 data rates. The received serial data passes through the receiver CDR, deserializer, word aligner, and

rate matching FIFO buffer. The data is then looped back to the transmitter serializer and transmitted out through the transmitter buffer. The received data is also available to the FPGA fabric through the port. This loopback mode is compliant with the PCIe specification 2.0. Arria V GZ devices provide an input signal to enable this loopback mode.

Note: This is the only loopback option supported in PIPE configurations.

Figure 6-20: PCIe Reverse Parallel Loopback Mode Datapath

The grayed-out blocks are Inactive.

Supported Features for PCIe Gen3

The PCIe Gen3 hard PCS supports the Gen3 base specification. PCIe Gen3 operations can be configured using the Arria V GZ Hard IP for PCI Express IP or PHY IP Core for PCI Express.

In Arria V GZ Hard IP for PCI Express, selecting **PCIe Base Specification Version 3.0** or **PCI Express Base Specification Version 2.1** enables a 32-bit wide PIPE 3.0-like interface for Gen1, Gen2, and Gen3 operations.

In PHY IP Core for PCI Express, selecting Gen3 enables the 32-bit wide PIPE 3.0-like interface and selecting Gen1 or Gen2 enables the 16-bit/8-bit wide PIPE 2.0 interface for Gen1 and Gen2 operation.

Block Synchronization (Word Aligner)

The block synchronizer aligns the recovered serial data coming from the CDR to 130-bit word boundaries. The block synchronizer delineates the word boundaries by searching and identifying the Electrical IDLE Exit Sequence Ordered Set (EIEOS) or the Last FTS OS and SKP ordered set to correctly identify the word boundary from the incoming serial data stream. The block synchronizer continues to realign to a new block boundary following the receipt of an SKP ordered set because of varying word lengths.

Gen3 Rate Match FIFO

To accommodate PCIe protocol requirements and to compensate for clock frequency differences of up to ±300 ppm between source and termination equipment, receiver channels have a rate match FIFO. The rate match FIFO adds or deletes four SKP characters (32 bits) to keep the FIFO from becoming empty or full. It monitors the block synchronizer for a `skip_found` signal. If the rate match FIFO is almost full, the FIFO deletes four SKP characters. If the rate match FIFO is nearly empty, the FIFO inserts an SKP character at the start of the next available SKP ordered set.

128B/130B Encoder/Decoder

Unlike PCIe Gen1 and Gen2, the PCIe Gen3 encoder/decoder does not use 8B/10B encoding. The PCIe Gen3 encoder/decoder uses a 2-bit sync header and a 128-bit data word. The PCS encoder appends the two sync header bits to every 128 bits of data and enables scrambling for the data packets except for ordered set packets and the first symbol of a TS1/TS2 ordered set. The encoder/decoder continuously enables or disables scrambling, based on whether the payload being processed is an ordered set or a data packet. If an Electrical IDLE Exit Ordered Set or a Fast Training Sequence Ordered Set is received, the scrambler is reset to the initial seed value. The encoder/decoder also monitors the data stream for ordered set and sync header bit violations.

Gen3 Gear Box

The PCIe 3.0 base specification requires a block size of 130 bits with the exception of SKP ordered sets, which can be 66, 98, 130, 162, or 194 bits in length. The 130-bit block of data generated by the 128B/130B encoder and variable length SKP characters must be reordered in 32-bit parallel data segments that the PMA serializer can accept. The transceivers employ a gear box to accommodate this fractional bit difference between the 130-bit data word and a fixed 32-bit serialization PMA factor for Gen3.

Scrambler/Descrambler

Scrambling and descrambling are used during PCIe Gen3 operation to guarantee adequate transitions for the receiver in order to correctly regenerate the recovered clock. The 2-bit sync header bit, ordered set, and the first symbol of the TS1/TS2 ordered set are never scrambled.

PIPE 3.0-Like Gen3 Interface

PCIe Gen3 is a new feature added to the transceivers. The PCS supports PCI Express 3.0 base specification. The PIPE interface has been expanded to a 32-bit wide PIPE 3.0-like interface. The PIPE interface controls PHY functions such as transmission of electrical idle, receiver detection, and speed negotiation and control. In summary, the Gen3 PIPE 3.0-like interface block performs the following:

- Dynamic clock selection between Gen1, Gen2, and Gen3 speeds
- Gen3 auto speed negotiation (ASN)
- Controlling the 128B/130B encoder/decoder
- Gen3 Electrical Idle Entry and Exit detections/CDR Control Block
- Dynamic Gen3 and Gen2/Gen1 PCS data rate Auto Speed Negotiation
- Dynamic transceiver PMA data rate and PLL switching

Auto-Speed Negotiation Block

PCIe Gen3 mode enables ASN (auto-speed negotiation) between Gen1 (2.5 Gbps), Gen2 (5.0 Gbps), and Gen3 (8.0 Gbps) signaling data rates. The signaling rate switch is accomplished through frequency scaling and configuration of the PMA and PCS blocks using a fixed 32-bit wide PIPE 3.0-like Interface.

The PMA switches clocks between Gen1, Gen2, and Gen3 data rates in a glitch-free manner. For a non-bonded x1 channel, an ASN module facilitates speed negotiation in that channel. For bonded x2, x4, and x8 channels, the ASN module selects the master channel to control the rate switch. The master channel distributes the speed change request to the other PMA and PCS channels.

Table 6-6: PIPE Gen3 32-Bit PCS Clock Rates

PCIe Gen3 Capability Mode Enabled	Gen1	Gen2	Gen3
Lane data rate	2.5G	5G	8G
PCS clock frequency	250 MHz	500 MHz	250 MHz
FPGA Core IP clock frequency	62.5 MHz	125 MHz	250 MHz
PIPE interface width	32-bit	32-bit	32-bit
Rate[1:0]	00	01	10

The PCIe Gen3 speed negotiation process is initiated by writing a 1 to bit 5 of the Link Control register of the root port, causing a PIPE rate signal change from the hard IP. The ASN then places the PCS in reset, dynamically shuts down the clock paths to disengage the current active state PCS (either Standard PCS or Gen3 PCS). If a switch to or from Gen3 is requested, the ASN automatically selects the correct PCS clock paths and datapath selection in the multiplexers. The ASN block then sends a request to the PMA block to switch the data rate change and waits for a rate change done signal for confirmation. When the PMA completes the rate change and sends confirmation to the ASN block, ASN enables the clock paths to engage the new PCS block and releases the PCS reset. Successful completion of this process is indicated by assertion of the `pipe_phystatus` signal by the ASN block to the hard IP block.

Note: In PHY IP Core for PCI Express configuration, the Core IP must set the values to `pipe_rate[1:0]` to initiate the transceiver datarate switch sequence.

Note: When you switch speeds to either Gen2 or Gen3, hold the LTSSM steady for 700 µs in Recovery.RCVRLOCK. The `rx_is_lockedtodata` signal from the CDR must be stable during this time. The PHY MAC interface should not look at `rxvalid` during this time because its contents may be invalid.

Transmitter Electrical IDLE Generation

The PIPE 3.0-like interface under the control of the hard IP block in Hard IP for PCIe or the user Core IP in PHY IP Core for PCIe may place the transmitter in electrical idle during low power states and the ASN process. Before the transmitter enters electrical idle, the HIP sends an electrical idle order set (EIOS) to the PHY. For Gen1 and Gen2, the order set format is COM, IDL, IDL, IDL. For Gen3, the order set format consists of 16 symbols with value 0x66.

During electrical idle, the transmitter differential and common mode voltage levels are compliant to the PCIe Base Specification 3.0.

Receiver Electrical IDLE Inference

If there is no activity on the link for a period of time or during the ASN process, the Inferring Electrical Idle condition is detected by the receiver PHY. These conditions are specified according to Table 4-11 of the PCI Express Base Specification, Rev 3.0.

Gen3 Power State Management

The PCIe base specification defines low power states for PHY layer devices to minimize power consumption. The Gen3 PCS does not implement these power saving measures, except when placing the

transmitter driver in electrical idle state in the low power states. In P2 low power state, the transceivers do not disable the PIPE block clock.

CDR Control Block

The CDR control block controls the PMA CDR to obtain bit and symbol alignment and deskew within the allocated time, and generates status signals for other PCS blocks. The PCIe base specification requires that the receiver L0s power state exit time be a maximum of 4 ms for Gen1, 2 ms for Gen2, and 4 ms for Gen3 signaling rates. The transceivers have an improved CDR control block to accommodate fast lock times when the CDR must relock to the new multiplier/divider settings when entering or exiting Gen3 speeds.

Transceiver Clocking and Channel Placement Guidelines

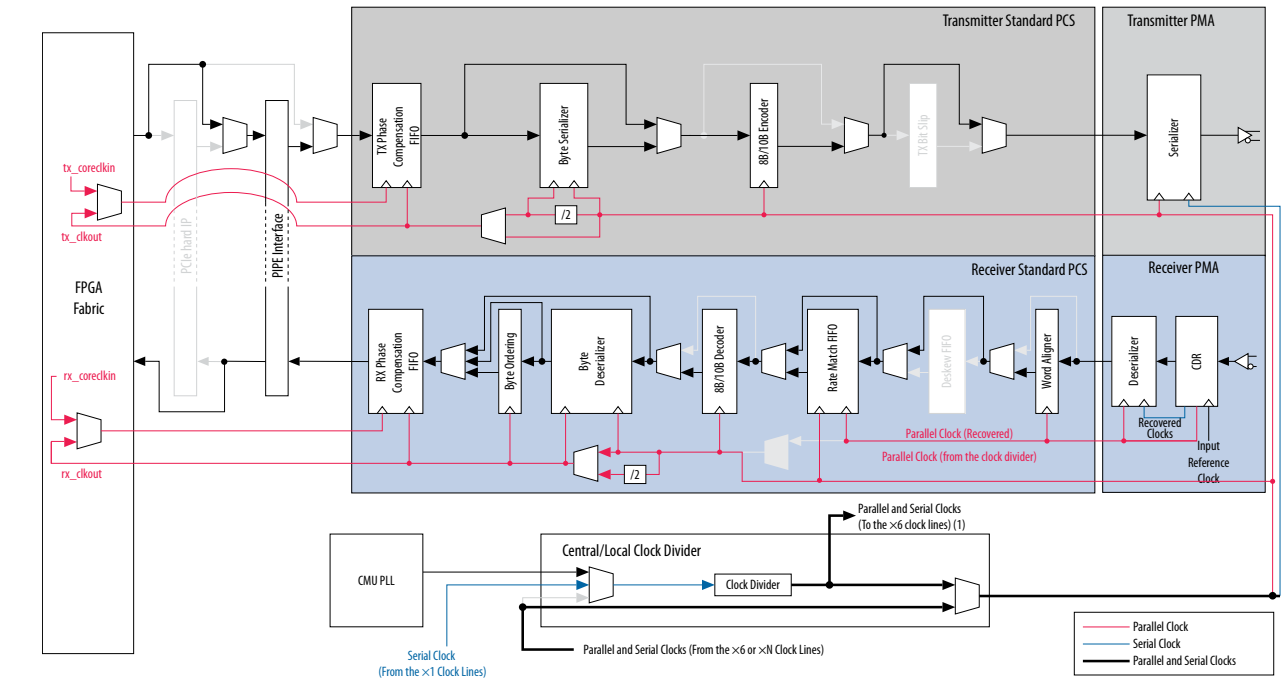
This section describes the transceiver clocking for Gen1 and Gen2 Hard IP and PIPE configurations. The channel placement guidelines are only described for Gen1 and Gen2 PIPE configuration. The channel placement guidelines for Gen1 and Gen2 Hard IP configuration are not included.

Transceiver Clocking for PCIe Gen1 and Gen2

PIPE x1 Configuration

The high-speed serial clock is provided by the CMU PLL in a channel different from that of the data channel. The local clock divider block in the data channel generates a parallel clock from this high-speed clock and distributes both clocks to the PMA and PCS of the data channel.

Figure 6-21: Transceiver Clocking in a Gen1/Gen2 PIPE x1 Configuration

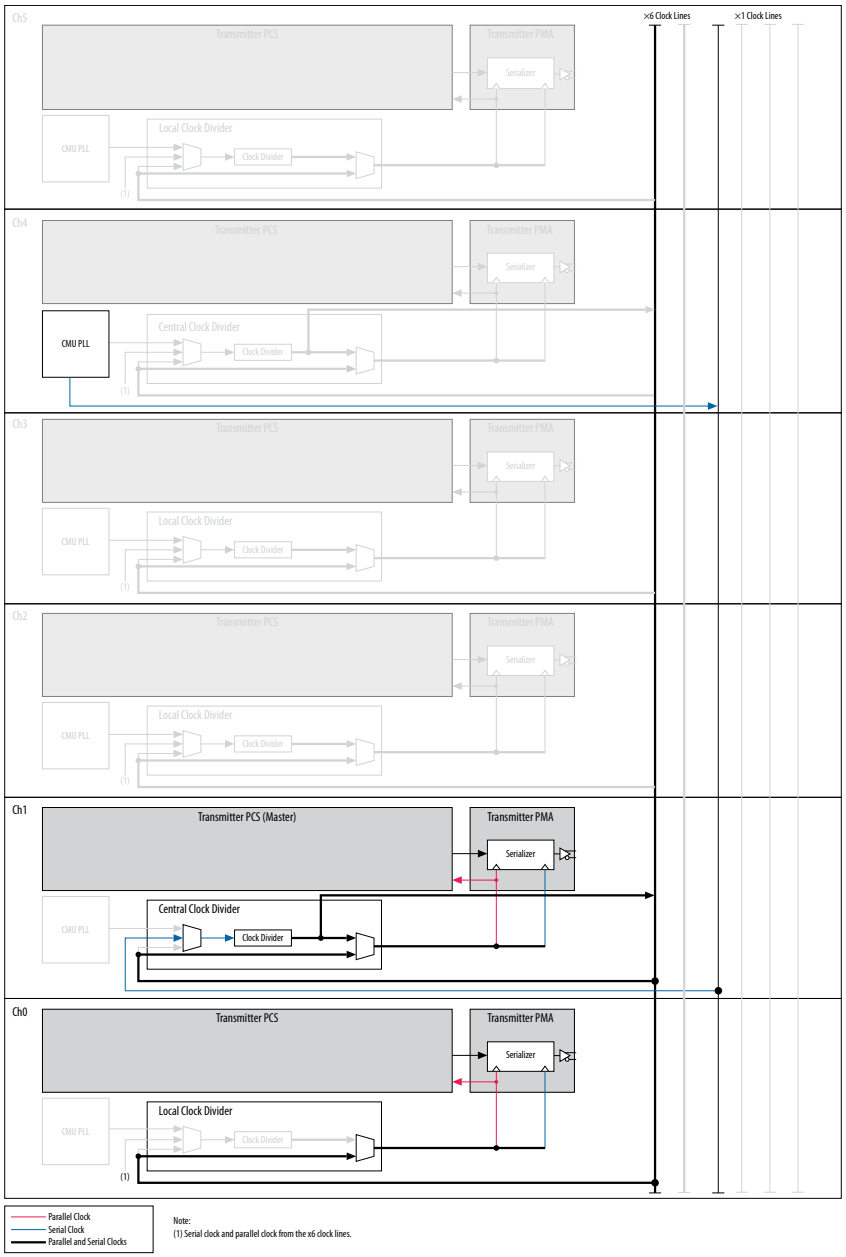


PIPE x2 Configuration

In a PIPE x2 bonded configuration, clocking within the PCS is independent for each receiver channel. Clocking is bonded only for transmitter channels, while the control signals are bonded for both

transmitter and receiver channels. The Quartus II software automatically places the transmit CMU PLL and master channel in either channel 1 or channel 4 within a transceiver bank

Figure 6-22: Transmitter Clocking in a Gen1/Gen2 PIPE x2 Configuration



PIPE x4 Configuration

In a PIPE x4 bonded configuration, clocking within the PCS is independent for each receiver channel. Clocking is bonded only for transmitter channels, while the control signals are bonded for both transmitter and receiver channels. The Quartus II software automatically places the transmit CMU PLL and master channel in either channel 1 or channel 4 within a transceiver bank.

Figure 6-23: Transmitter Clocking in a Gen1/Gen2 PIPE x4 Configuration

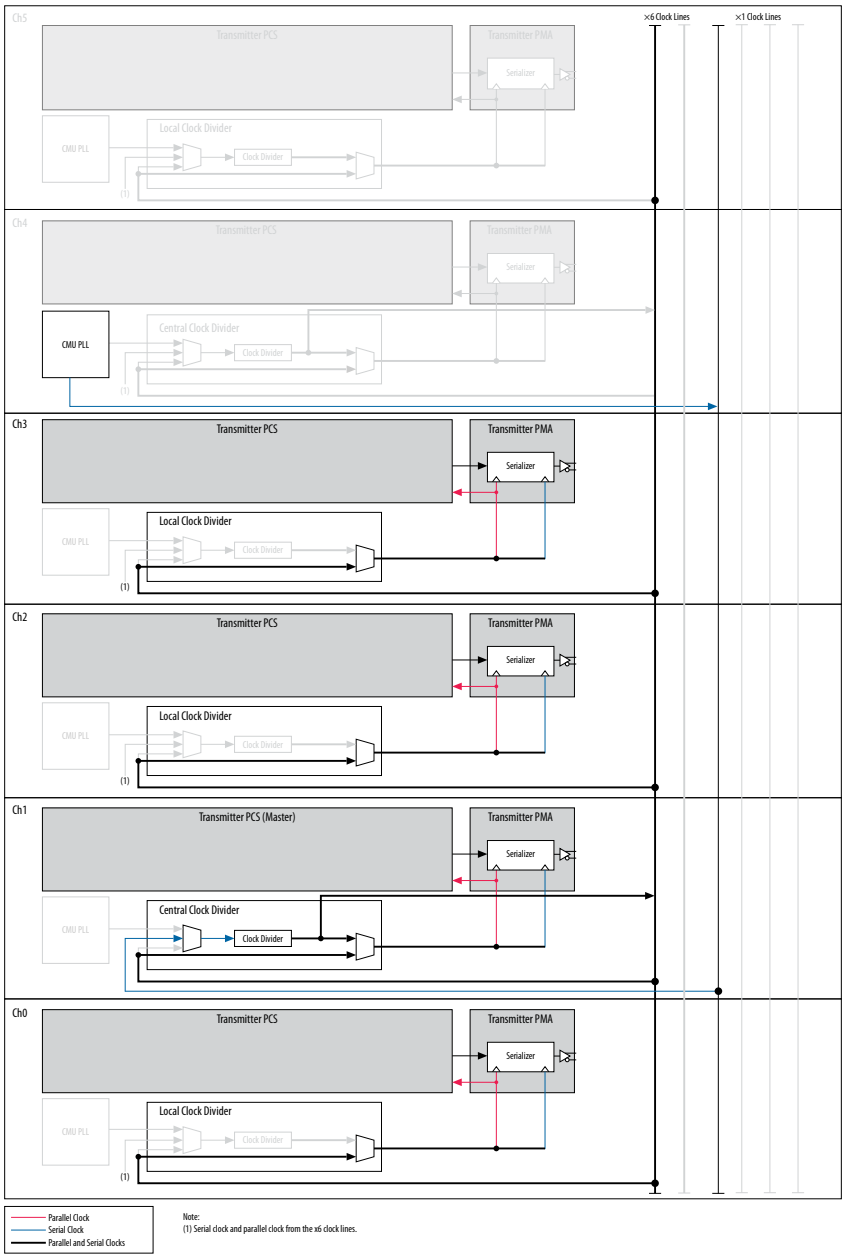


Figure 6-24: Receiver Clocking in a Gen1/Gen2 PIPE x4 Configuration

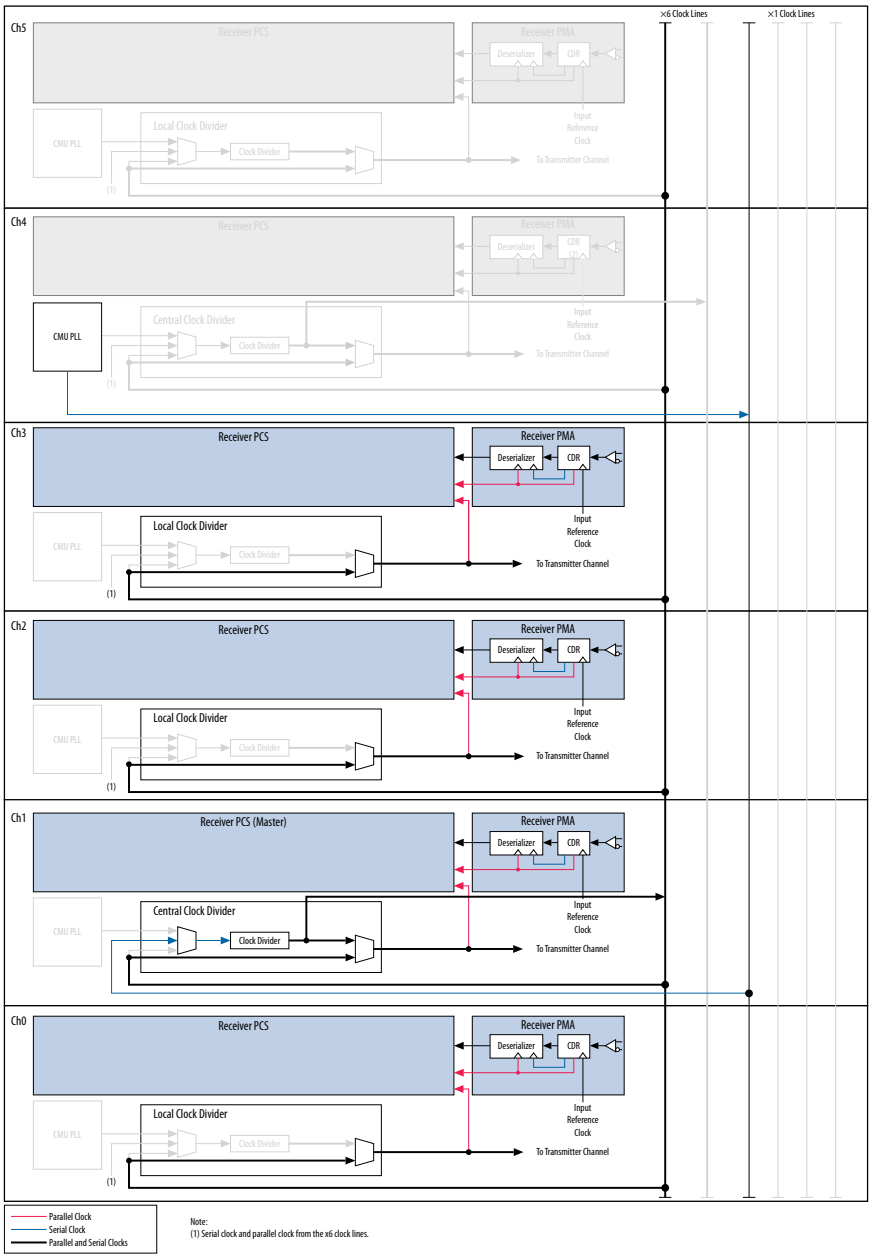
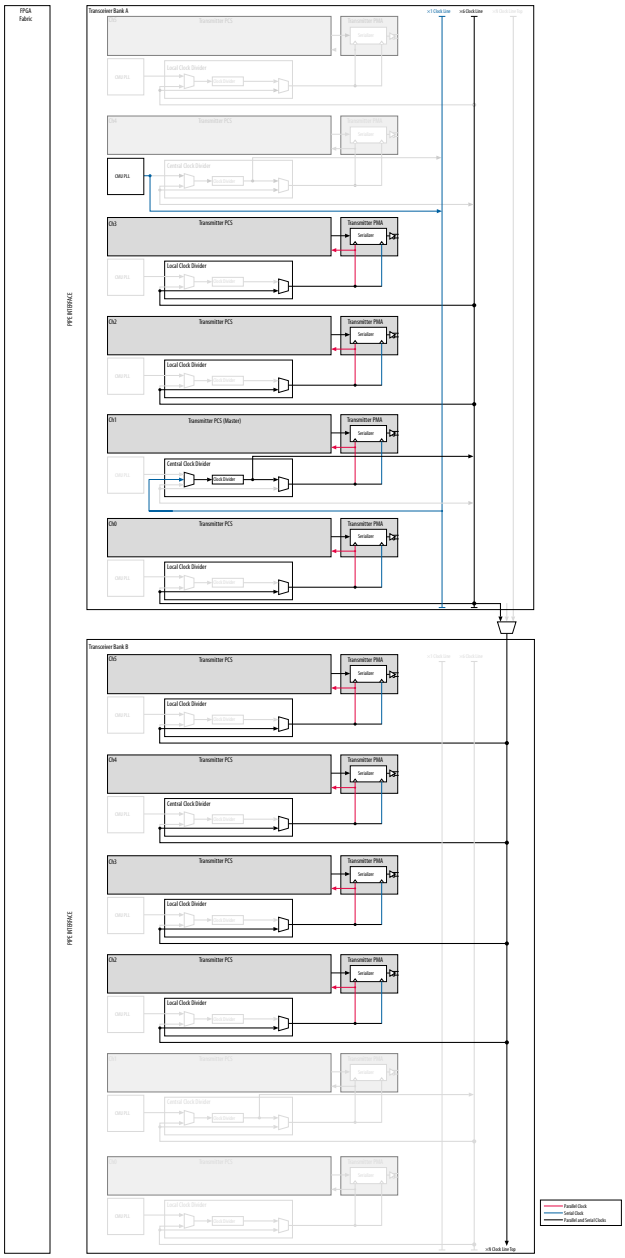


PIPE x8 Configuration

In the x8 PCIe bonded configuration, clocking is independent for receiver channels. Clocking and control signals are bonded only for transmitter channels.

Figure 6-25: Transceiver Clocking in a Gen1/Gen2 PIPE x8 Configuration



Transceiver Channel Placement Guidelines for Gen1, Gen2, and Gen3 PIPE Configurations

Note: The channel placement guidelines are only described for Gen1, Gen2, and Gen3 x1, x2, x4, and x8 PIPE configurations. The channel placement guidelines for Gen1, Gen2, and Gen3 Hard IP configuration are not included.

The following table lists the physical placement of PIPE channels in x1, x2, x4, and x8 bonding configurations. The Quartus® II software automatically places the CMU PLL in a channel different from that of the data channels.

Table 6-7: PIPE Configuration Channel Placement

Placement by the Quartus II software may vary with design, thus resulting in higher channel usage.

Configuration	Data Channel Placement	Channel Utilization Using CMU PLL in Gen1 and Gen2	Channel Utilization Using ATX PLL in Gen1 and Gen2	Channel Utilization Using CMU and ATX PLL in Gen3
x1	Any channel	2	1	2
x2	Contiguous channels	3	2	3
x4	Contiguous channels	5	4	5
x8	Contiguous channels	9	8	9

Channel Placement for Gen1, Gen2, and Gen3 x1 PIPE Configuration

For PIPE x1 configurations, the channel can be placed anywhere within a transceiver bank that contains the transmitter PLL. In Gen1 and Gen2 configurations, you can select either the ATX PLL or the CMU PLL as the transmitter PLL. In Gen3 configurations, a CMU PLL is used for Gen1 and Gen2 datarates and an ATX PLL is used for Gen3 datarates.

Channel Placement for Gen1, Gen2, and Gen3 x2 and x4 PIPE Configuration

The following two figures show examples of channel placement for PIPE x2 and x4 configurations. In a PIPE x2 or x4 configuration, the two or four channels must be contiguous and within the same transceiver bank, but they can be placed in any order as long as Logical Lane 1 is placed on the master channel. In Gen1 and Gen2 configurations, you can select either the ATX PLL or the CMU PLL as the transmitter PLL. In Gen3 configurations, a CMU PLL is used for Gen1 and Gen2 datarates and an ATX PLL is used for Gen3 datarates. The CMU PLL and/or ATX PLL must be within the same transceiver bank as the master channel.

In the figures, channels shaded in blue provide the transmit CMU PLL generating the high-speed serial clock. Channels shaded in gray are data channels. The Quartus II software automatically selects one of the following within a transceiver bank:

- The CMU PLL in either channel 1 or channel 4.
- The upper or lower ATX PLL if the ATX PLL is selected as the transmitter PLL within the transceiver bank containing the master channel.

Gen3 channel placement requires both a CMU and an ATX PLL in the same transceiver bank as the master channel.

Figure 6-26: Example of PIPE x2 Gen1, Gen2, and Gen3 Channel Placement Using an ATX PLL, a CMU PLL, or Both

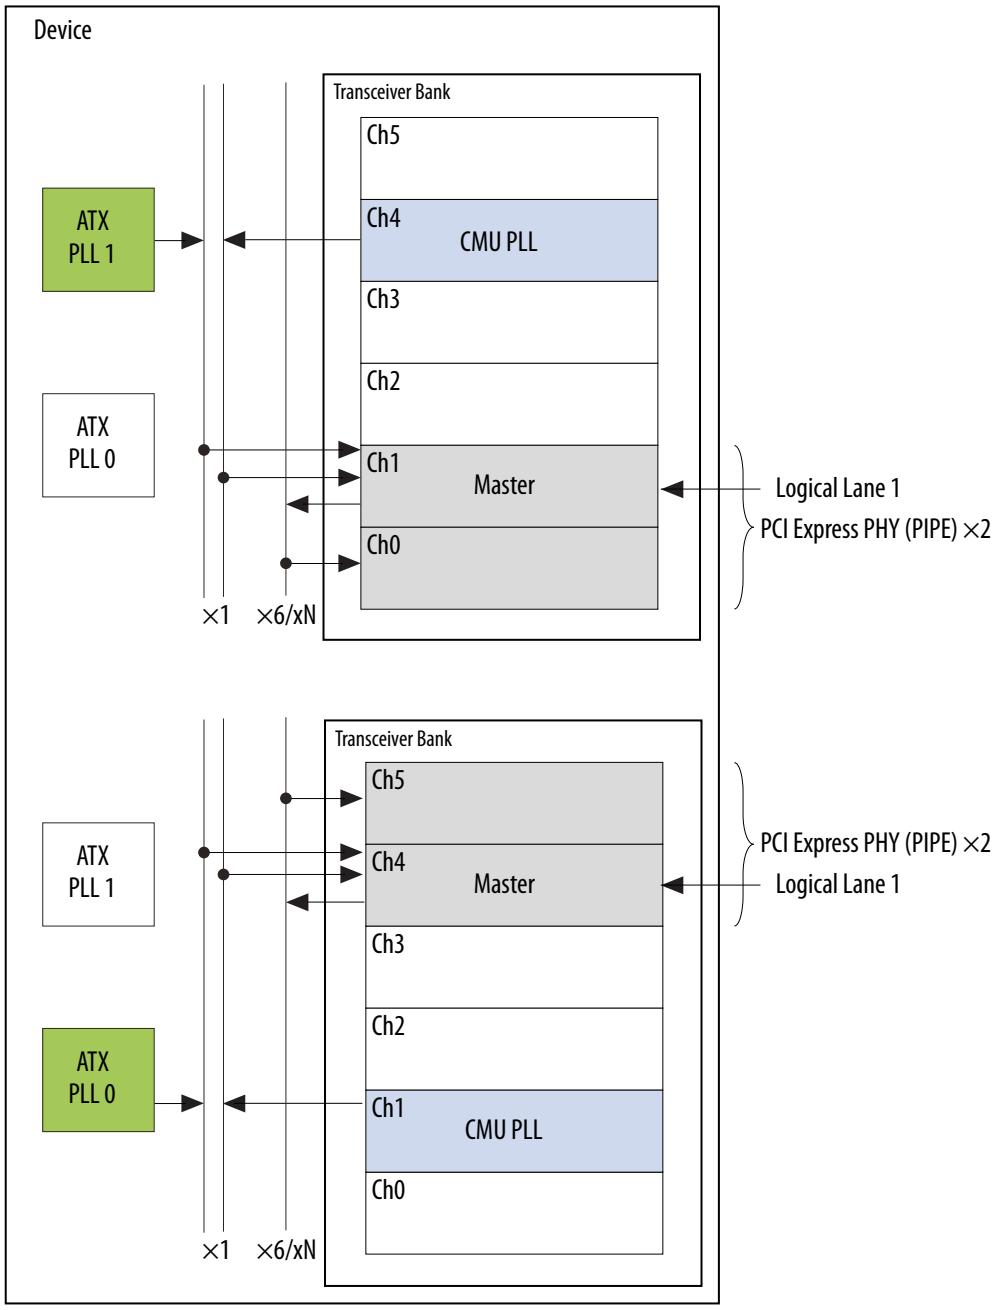


Figure 6-27: Example of PIPE x4 Gen1, Gen2, and Gen3 Channel Placement Using an ATX PLL, a CMU PLL, or Both

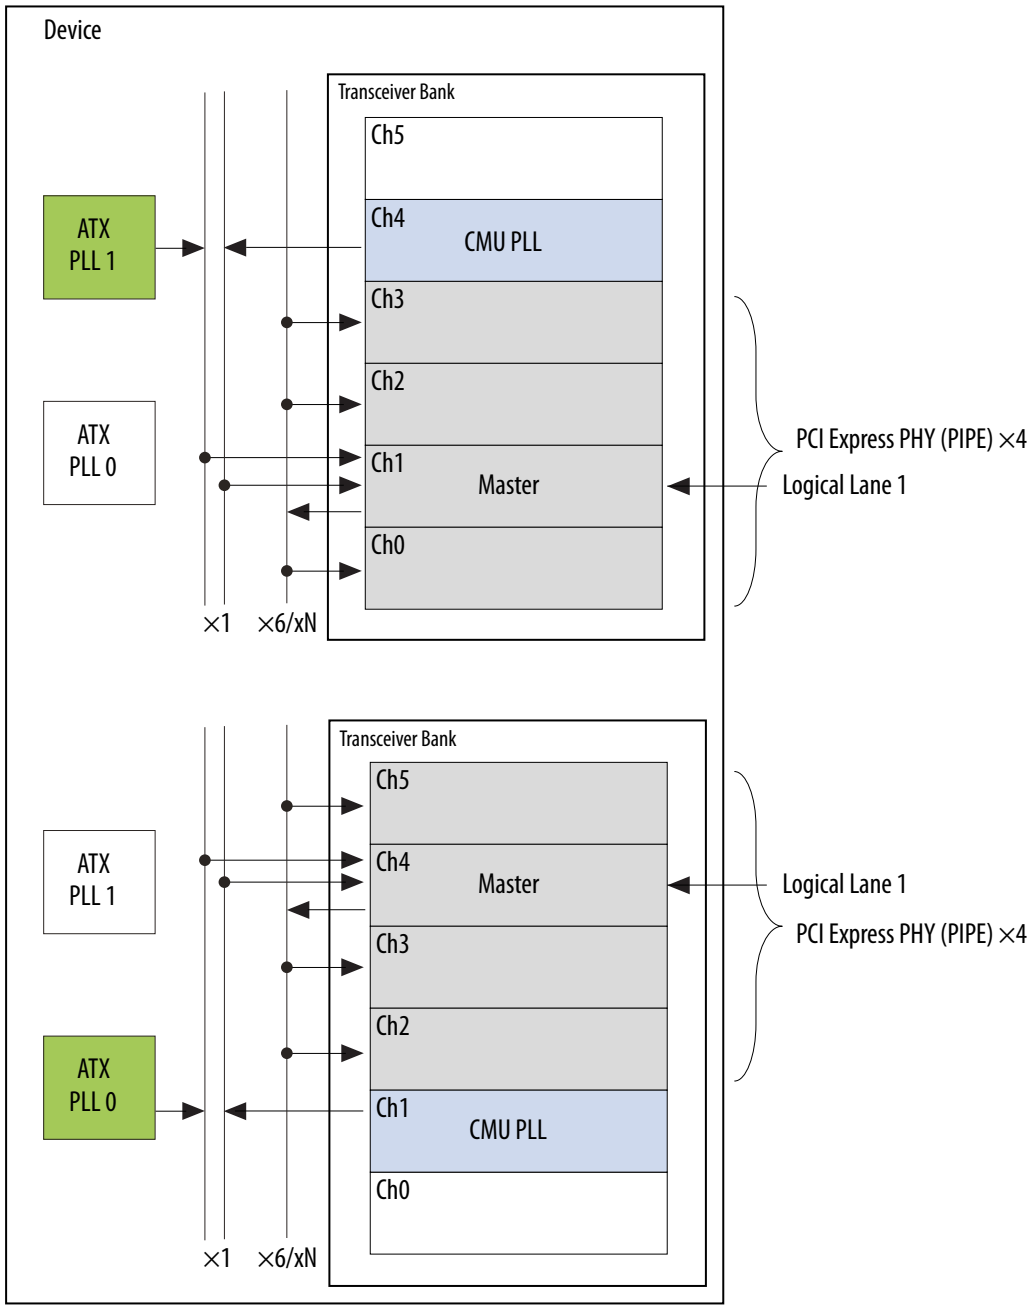
Channels shaded in blue provide the transmit CMU PLL generating the high-speed serial clock. Channels shaded in gray are data channels. The Quartus II software automatically selects the CMU PLL in either channel 1 or channel 4 within a transceiver bank. Gen3 channel placement requires an additional ATX PLL in the same transceiver bank as the master channel.



Channel Placement for Gen1, Gen2, and Gen3 x8 PIPE Configuration

In a PIPE x8 configuration, the eight channels must be contiguous, but they can be placed in any order as long as Logical Lane 0 is placed on the master channel.

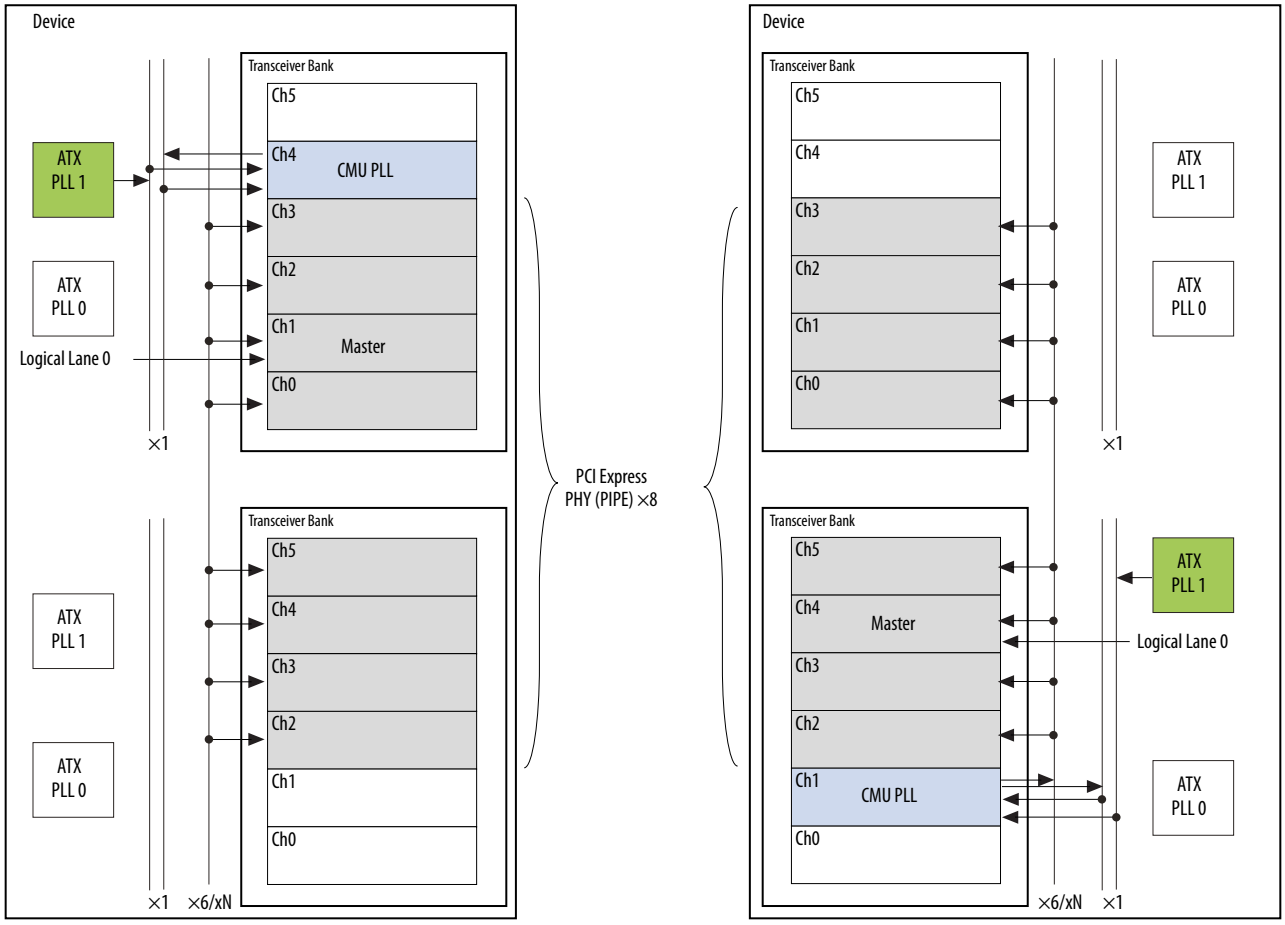
The Quartus II software automatically selects one of the following within a transceiver bank:

- The CMU PLL in either channel 1 or channel 4.
- The upper or lower ATX PLL if the ATX PLL is selected as the transmitter PLL within the transceiver bank containing the master channel.

In Gen1 and Gen2 configurations, you can select either the ATX PLL or the CMU PLL as the transmitter PLL. In Gen3 configurations, a CMU PLL is used for Gen1 and Gen2 datarates and an ATX PLL is used for Gen3 datarates. The CMU PLL and/or ATX PLL must be within the same transceiver bank.

Figure 6-28: Example of PIPE x8 Gen1, Gen2, and Gen3 Channel Placement Using an ATX PLL, a CMU PLL, or Both

Channels shaded in blue provide the transmit CMU PLL generating the high-speed serial clock. Channels shaded in gray are data channels. Gen3 channel placement requires both a CMU and ATX PLL in the same transceiver bank as the master channel.



Related Information

For channel placement guidelines for PCIe hard IP configuration using the Hard IP for PCI Express, refer to the Arria V Hard IP for PCI Express User Guide.

Advanced Channel Placement Guidelines for PIPE Configurations

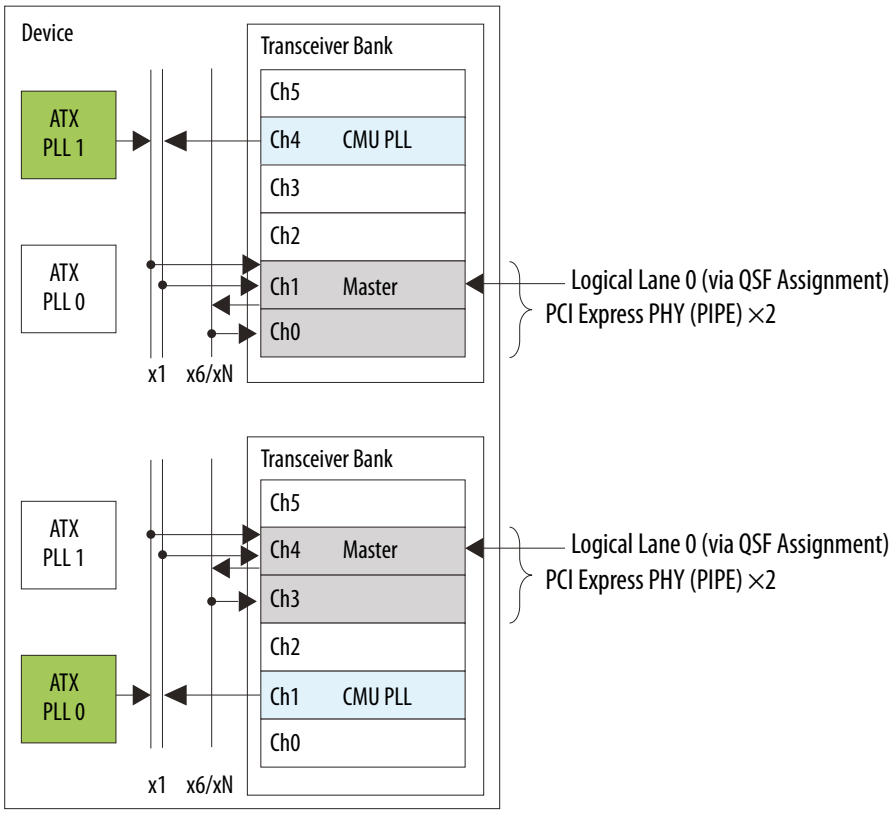
Advanced channel placement options for PIPE configurations are enabled through Quartus Settings File (QSF) assignments. A QSF assignment allows you to override the master channel assignment. By using a

QSF assignment, master channels can be assigned any logical channel number instead of the default Quartus II logical lane assignment. Any PIPE channel placement can also be made compatible with the HIP configuration channel placement.

In the following figures, channels shaded in blue provide the transmit CMU PLL generating the high-speed serial clock. Channels shaded in gray are data channels. An ATX PLL shaded in green can be substituted for the CMU PLL for Gen1 and Gen2 configurations only. Gen3 channel placement requires both the CMU PLL for Gen1/Gen2 datarates and the ATX PLL for Gen3 datarates to be located in the same transceiver bank as the master channel. The Quartus II software automatically selects the CMU PLL in either channel 1 or channel 4 and/or the upper or lower ATX PLL within a transceiver bank.

Advanced Channel Placement for PIPE x2 Gen1, Gen2, and Gen3 Configurations

Figure 6-29: PIPE x2 Gen1, Gen2, and Gen3 Advanced Channel Placement Using CMU and/or ATX PLL



Advanced Channel Placement for PIPE x4 Gen1, Gen2, and Gen3 Configurations

Figure 6-30: PIPE x4 Gen1, Gen2, and Gen3 Advanced Channel Placement Using CMU and/or ATX PLL in the Same Transceiver Bank

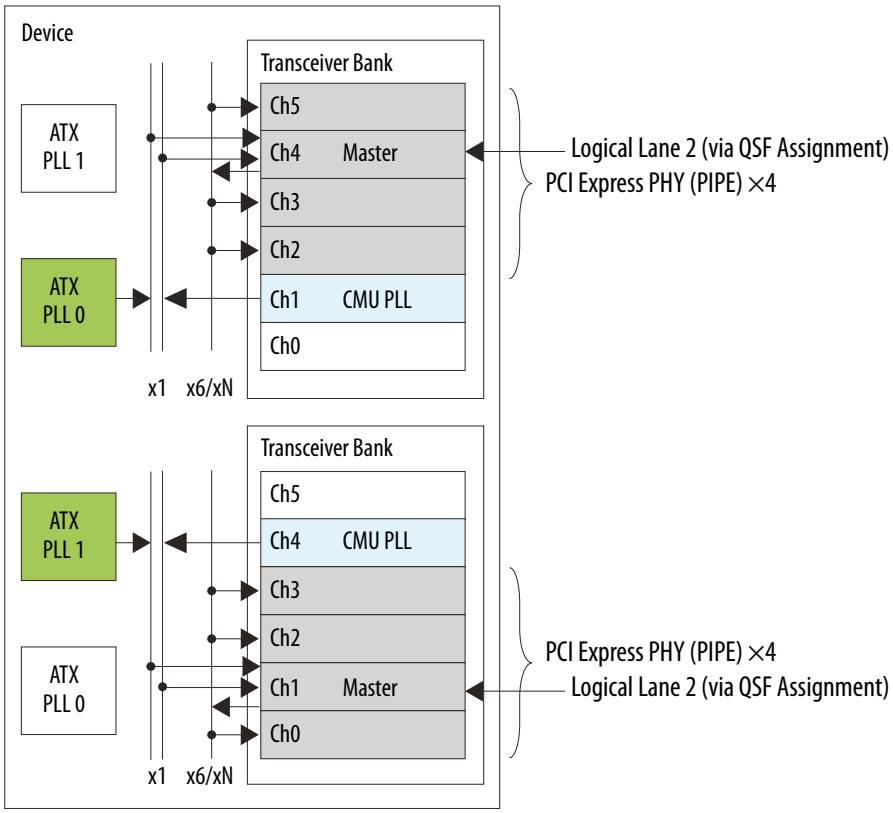


Figure 6-31: PIPE x4 Gen1, Gen2, and Gen3 Advanced Channel Placement Using CMU and/or ATX PLL Across Two Transceiver Banks – example 1

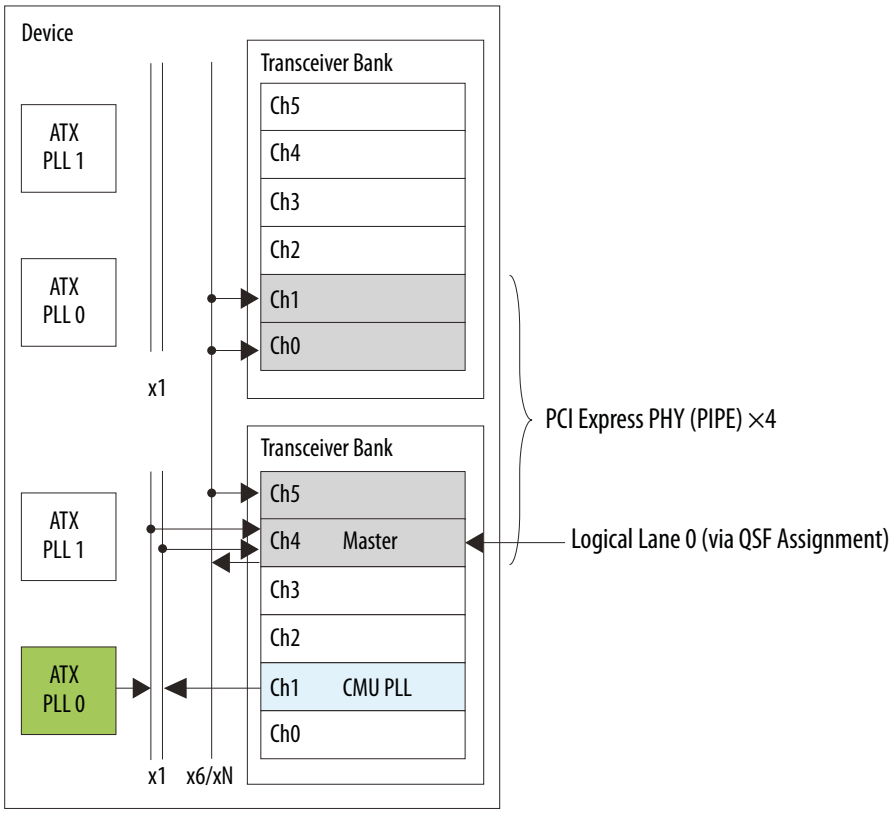

Figure 6-32: PIPE x4 Gen1, Gen2, and Gen3 Advanced Channel Placement Using CMU and/or ATX PLL Across Two Transceiver Banks – example 2

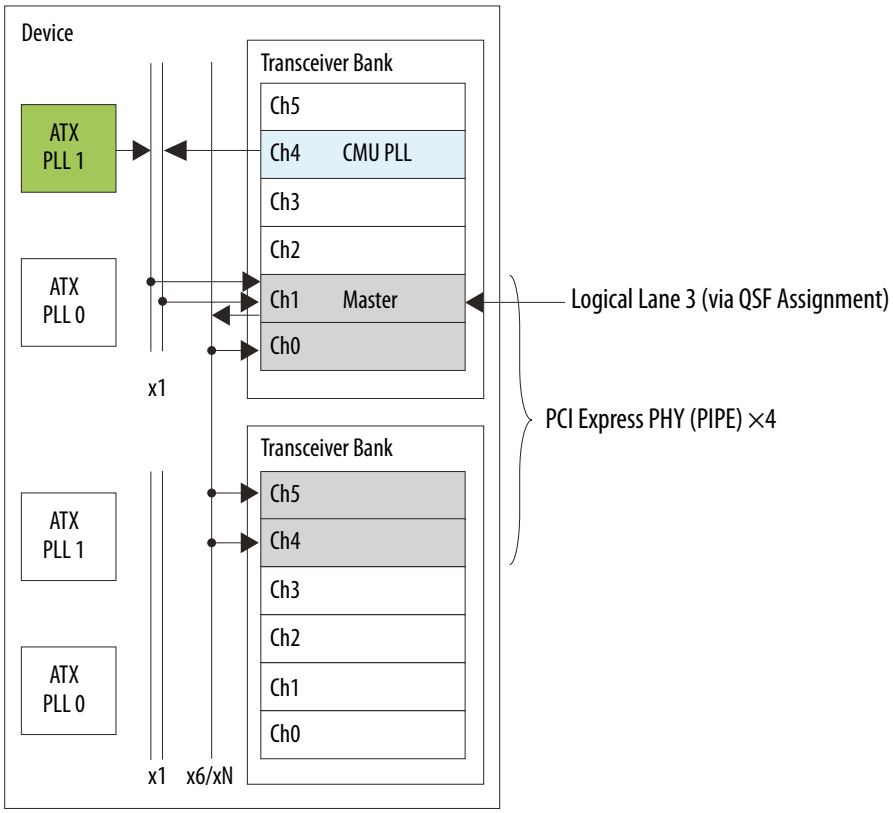

Advanced Channel Placement for PIPE x8 Gen1, Gen2, and Gen3 Configurations

For PCIe x8 advanced channel placement where the master channel resides between the contiguous data channel assignments, a second QSF assignment is required that allows the master channel to be placed between data channels.

For a HIP-compatible PCIe x8 channel placement, the master channel must be assigned logical channel 4 in the lower transceiver bank and the second QSF assignment for the reserve channel that allow master channel placement between contiguous data channel assignments are required.

Figure 6-33: PIPE x8 Gen1, Gen2, and Gen3 Advanced Channel Placement That is Compatible with HIP x8 Channel Placement

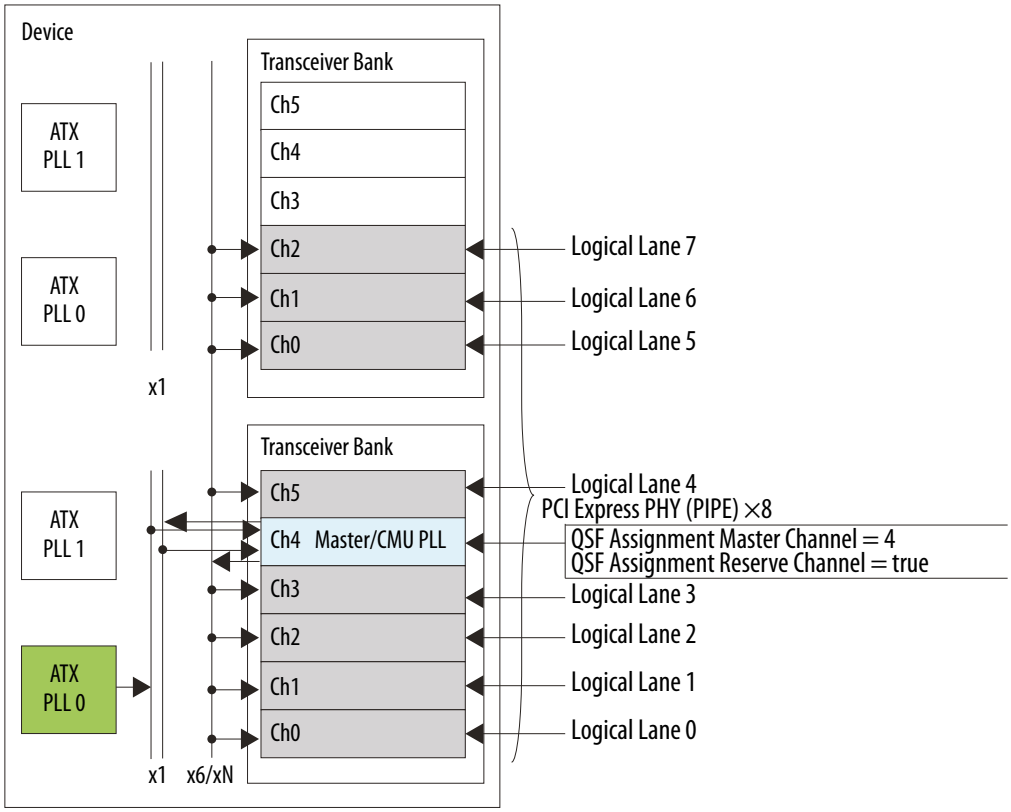

Figure 6-34: PIPE x8 Gen1, Gen2, and Gen3 Advanced Channel Placement That is Not Compatible with HIP x8 Channel Placement

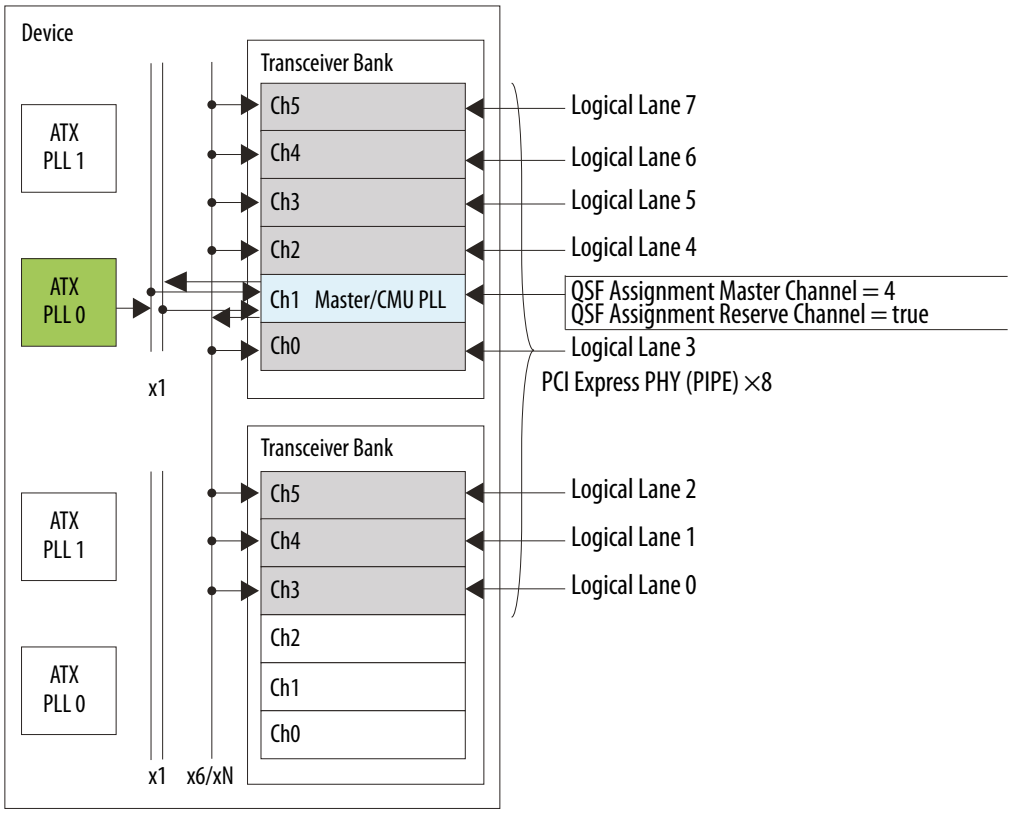

The following figures show PIPE x8 Gen1, Gen2, and Gen3 advanced channel placement that requires only a master channel QSF assignment.

Figure 6-35: PIPE x8 Gen1, Gen2, and Gen3 Advanced Channel Placement – example 1

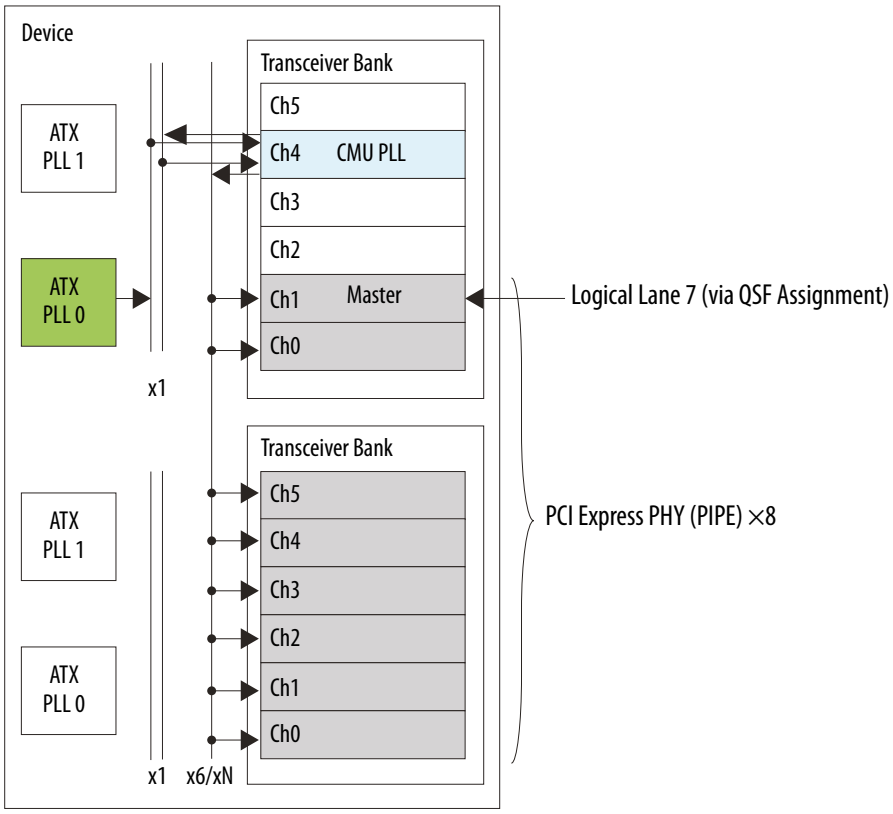

Figure 6-36: PIPE x8 Gen1, Gen2, and Gen3 Advanced Channel Placement – example 2

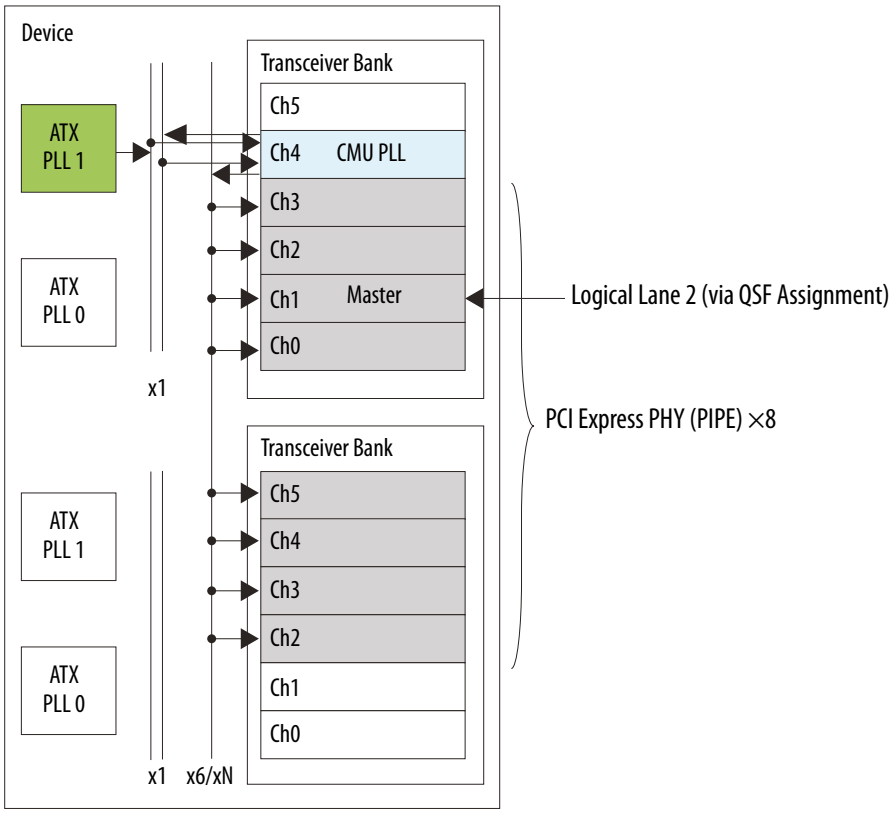

Figure 6-37: PIPE x8 Gen1, Gen2, and Gen3 Advanced Channel Placement – example 3

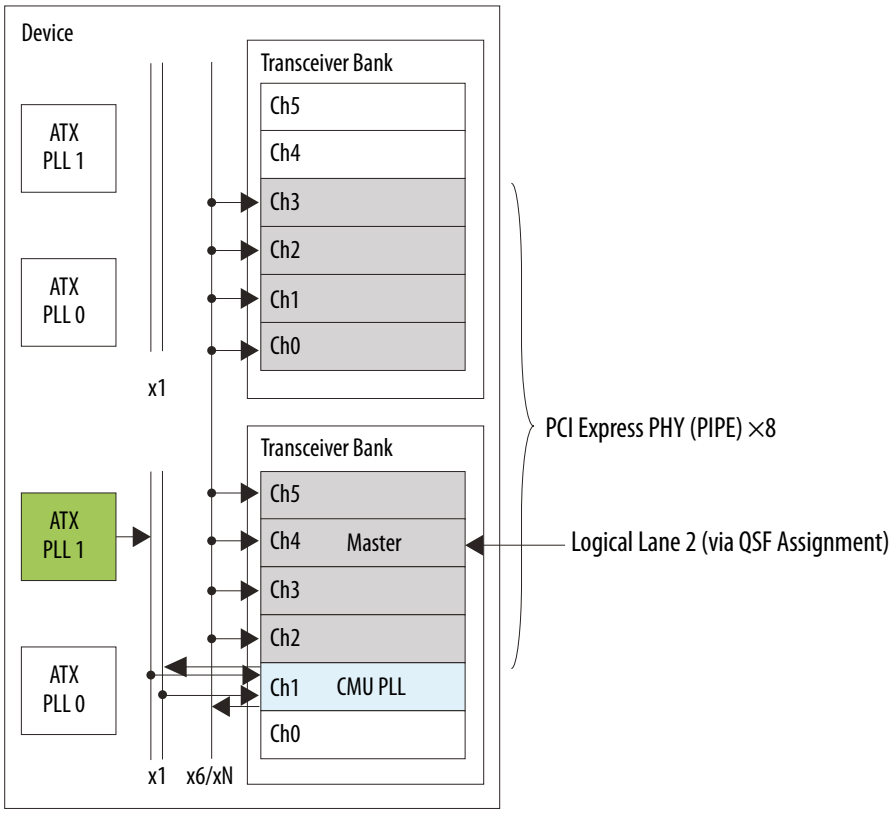


Transceiver Clocking for PCIe Gen3

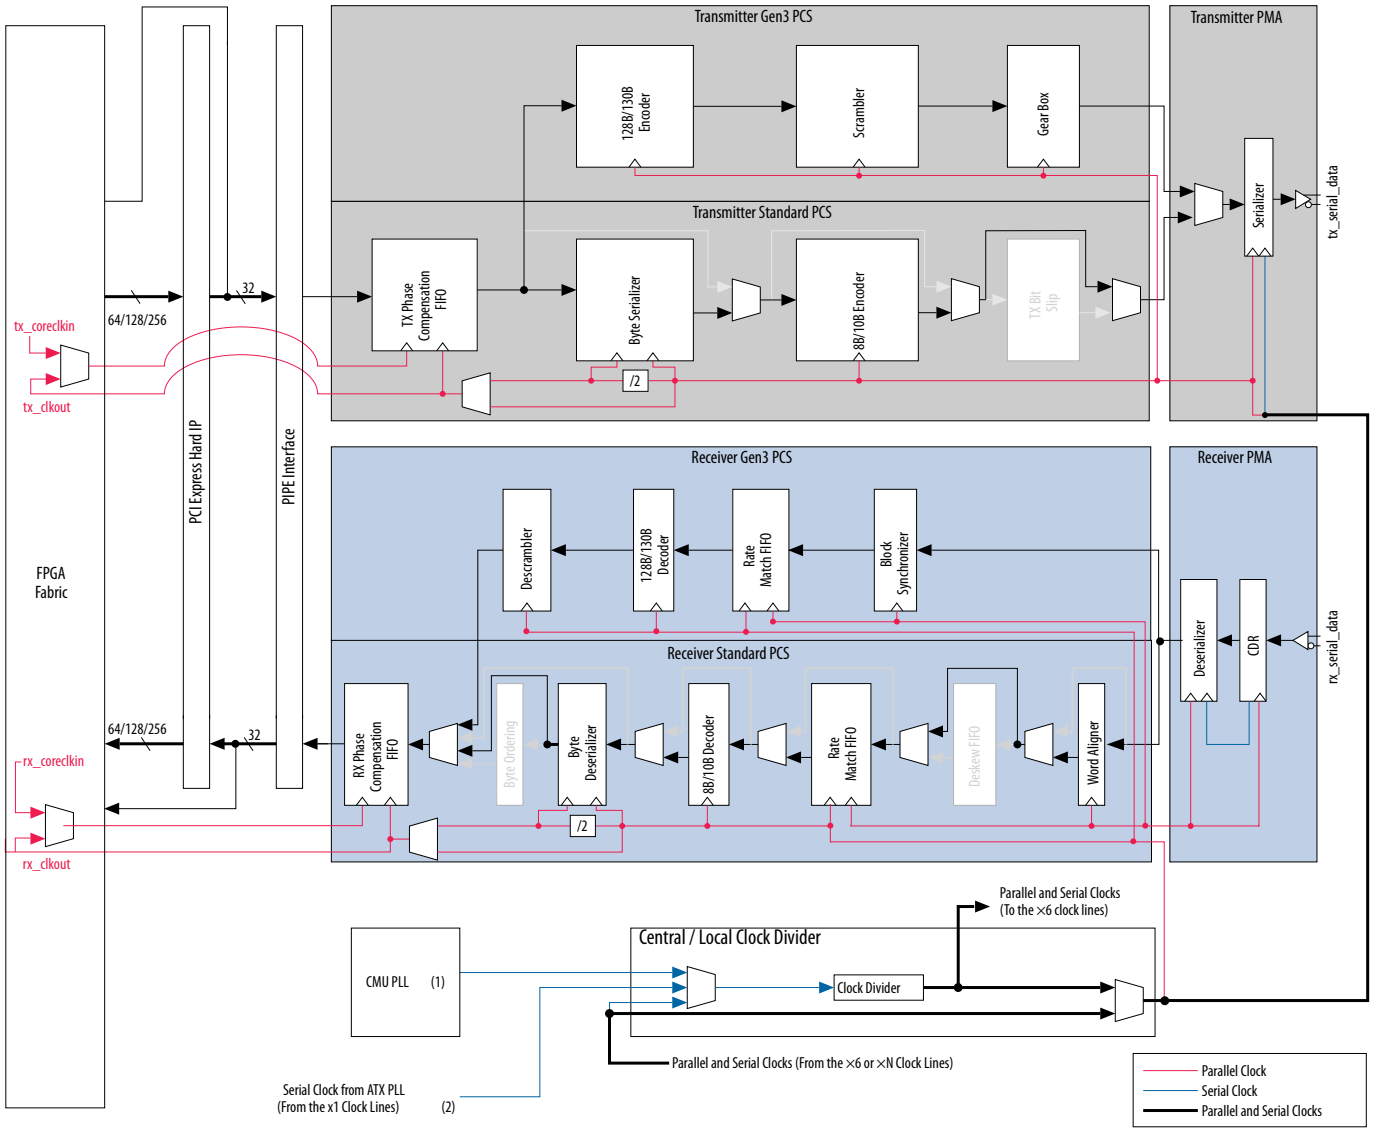
This section describes the transceiver clocking topology for both the PCIe Gen3 Hard IP and PIPE configuration.

In a PCIe x1, x2, x4, and x8 Gen3 Mode, both a channel PLL (CMU PLL) from transceiver physical channel 1 or 4 of the transceiver bank and either the top or bottom ATX PLL are used to generate the high-speed serial clock and support ASN. The CMU PLL supports Gen1 and Gen2 data rates while the ATX PLL supports Gen3 data rates. To enable rapid switching between Gen1, Gen2, and Gen3 data rates, a multiplexer selects either the free running CMU PLL for Gen1 and Gen2 data rates or the free running ATX PLL for Gen3 data rates. PLL reconfiguration is not used to support ASN.

Gen3 x1 Configuration

Figure 6-38: Transceiver Clocking in a Gen1/Gen2/Gen3 PCIe x1 Hard IP and PIPE Configuration

For Gen1 and Gen2, use the CMU PLL. For Gen3, use the ATX PLL.



For **PCIe x1 Gen3** using Hard IP configuration, the CMU PLL (transceiver physical channel 1) and the bottom ATX PLL of the transceiver bank are configured to generate the high-speed serial clock for the transmitter datapath clock and the rate matcher side of the FIFO in the receiver datapath if rate matching is enabled for the data channel. Two transceiver channels are needed to implement PCIe x1 Gen3, one for the data channel and one for the CMU PLL. The local clock divider block in the data channel generates a parallel clock from this high-speed serial clock and distributes both clocks to the PMA and PCS of the data channel.

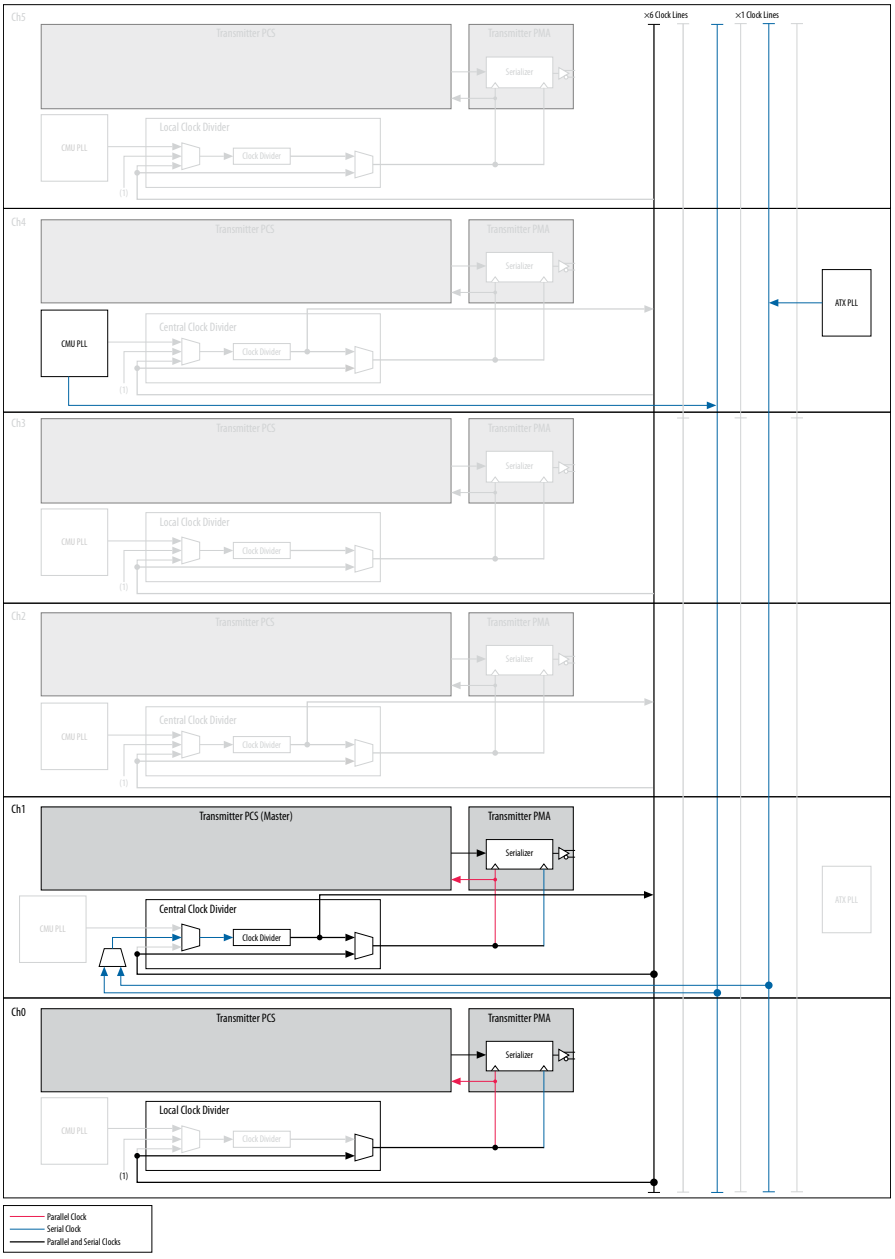
For **PCIe x1 Gen3** using PIPE configuration, the CMU PLL (transceiver physical channel 1 or 4) and the top or bottom ATX PLL of the transceiver bank are configured to generate the high-speed serial clock for the transmitter datapath clock and the rate matcher side of the FIFO in the receiver datapath if rate matching is enabled for the data channel. Two transceiver channels are needed to implement PCIe x1

Gen3, one for the data channel and one for the CMU PLL. The local clock divider block in the data channel generates a parallel clock from this high-speed serial clock and distributes both clocks to the PMA and PCS of the data channel.

Gen3 x2 Configuration

Figure 6-39: Transmitter Clocking in a Gen1/Gen2/Gen3 PCIe x2 Hard IP and PIPE Configuration

Unlike the Hard IP configuration, the PIPE configuration has the additional flexibility of using the top four transceiver channels in a transceiver bank or spanning the four lanes across two banks.



For **PCIe x2 Gen3** using Hard IP configuration, the CMU PLL (transceiver physical channel 4) and the top ATX PLL of the transceiver bank are configured to generate the high-speed serial clock. A total of three transceiver channels are required to implement PCIe x2 Gen3, including two data channels and one

channel for the CMU PLL. The Quartus II software automatically selects channel 1 in the transceiver bank as the master channel. Channel 1 bonds and drives all the transmitter datapath's clocking and the rate matcher side of the FIFO in the receiver datapaths if rate matching is enabled for the two data channels. The local clock divider block in each data channel generates the parallel clock from the high-speed serial clock and distributes both clocks to the PMA and PCS of that data channel.

For **PCIe x2 Gen3** using PIPE configuration, the CMU PLL (transceiver physical channel 1 or 4) and the top or bottom ATX PLL of the transceiver bank are configured to generate the high-speed serial clock. A total of three transceiver channels are required to implement PCIe x2 Gen3, including two data channels and one channel for the CMU PLL. The Quartus II software automatically selects either channel 1 or 4 in the transceiver bank as the master channel. Channel 1 or 4 bonds and drives all the transmitter datapath's clocking and the rate matcher side of the FIFO in the receiver datapaths if rate matching is enabled for the two data channels. The local clock divider block in each data channel generates the parallel clock from the high-speed serial clock and distributes both clocks to the PMA and PCS of that data channel.

Gen3 x4 Configuration

Figure 6-40: Transmitter Clocking in a Gen1/Gen2/Gen3 PCIe x4 Hard IP and PIPE Configuration

Unlike the Hard IP configuration, the PIPE configuration has the additional flexibility of using the top four transceiver channels in a transceiver bank or spanning the four lanes across two banks.

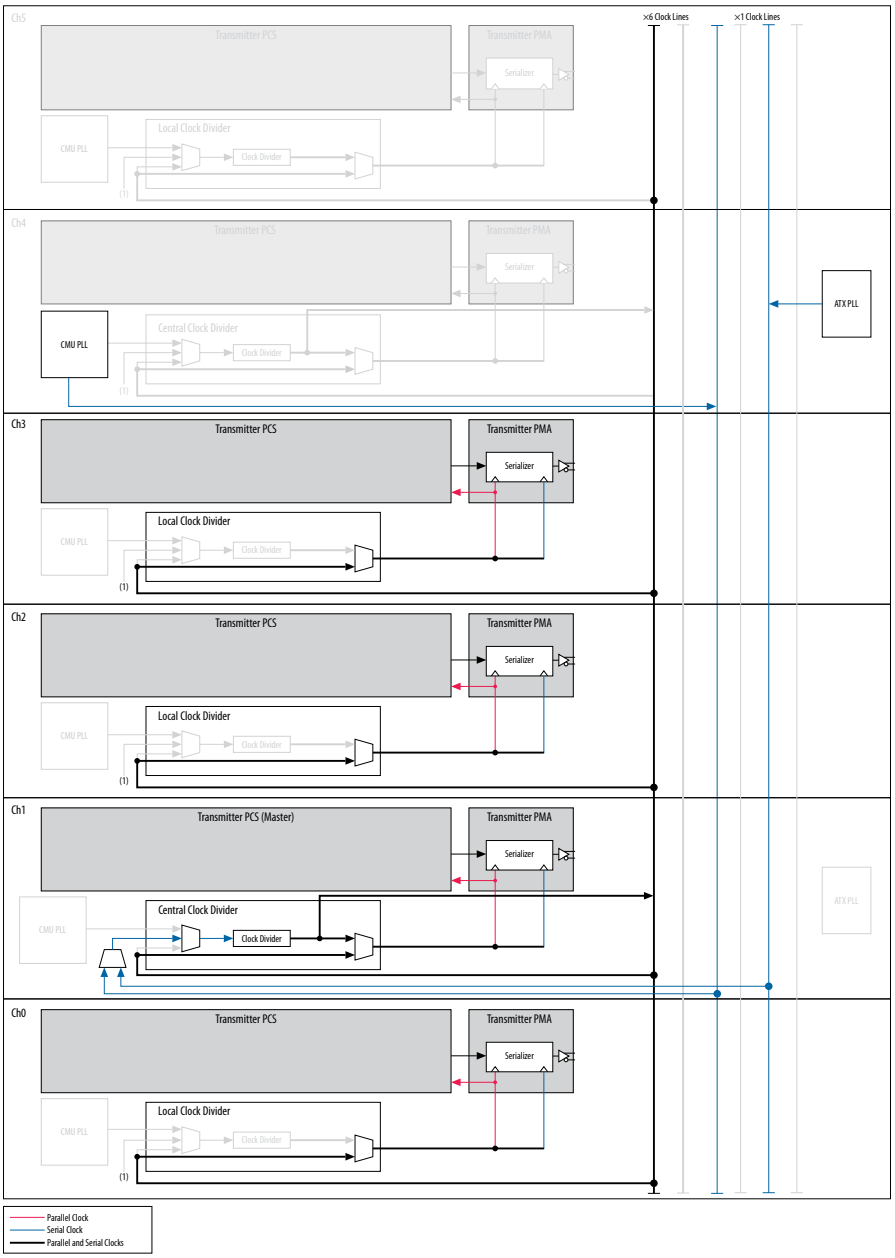


Figure 6-41: Receiver Clocking in a Gen1/Gen2/Gen3 PCIe x4 Hard IP and PIPE Configuration

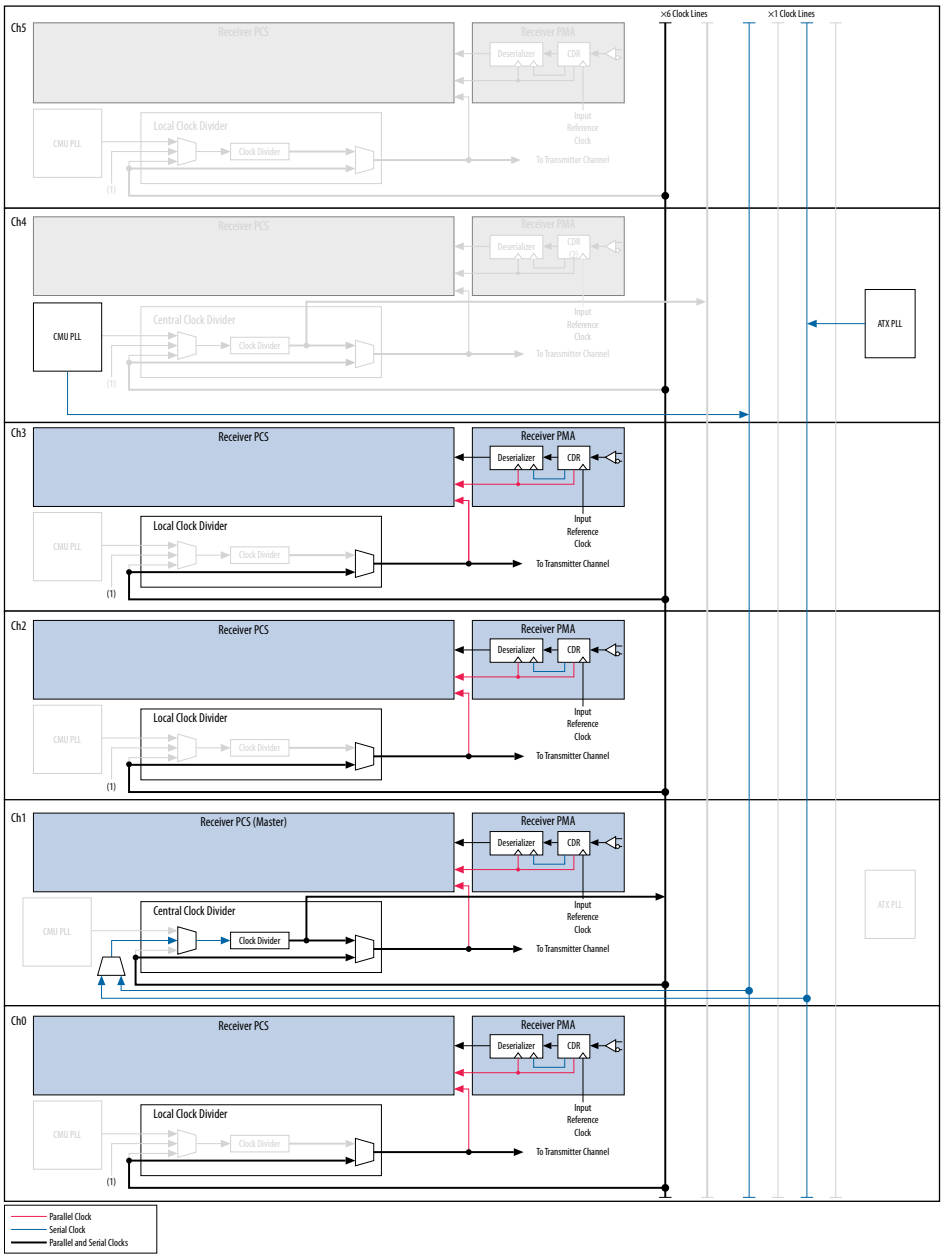


For **PCIe x4 Gen3** using Hard IP configuration, the CMU PLL (transceiver physical channel 4) and the top ATX PLL of the transceiver bank are configured to generate the high-speed serial clock. A total of five transceiver channels are required to implement PCIe x4 Gen3, including four data channels and one channel for the CMU PLL. The Quartus II software automatically selects channel 1 in the transceiver bank as the master channel. Channel 1 bonds and drives all the transmitter datapath's clocking and the rate matcher side of the FIFO in the receiver datapaths if rate matching is enabled for the four data channels. The local clock divider block in each data channel generates the parallel clock from the high-speed serial clock and distributes both clocks to the PMA and PCS of that data channel.

For **PCIe x4 Gen3** using PIPE configuration, the CMU PLL (transceiver physical channel 1 or 4) and the top or bottom ATX PLL of the transceiver bank are configured to generate the high-speed serial clock. A

total of five transceiver channels are required to implement PCIe x4 Gen3, including four data channels and one channel for the CMU PLL. The Quartus II software automatically selects either channel 1 or 4 in the transceiver bank as the master channel. Channel 1 or 4 bonds and drives all the transmitter datapath's clocking and the rate matcher side of the FIFO in the receiver datapaths if rate matching is enabled for the four data channels. The local clock divider block in each data channel generates the parallel clock from the high-speed serial clock and distributes both clocks to the PMA and PCS of that data channel.

Gen3 x8 Configuration

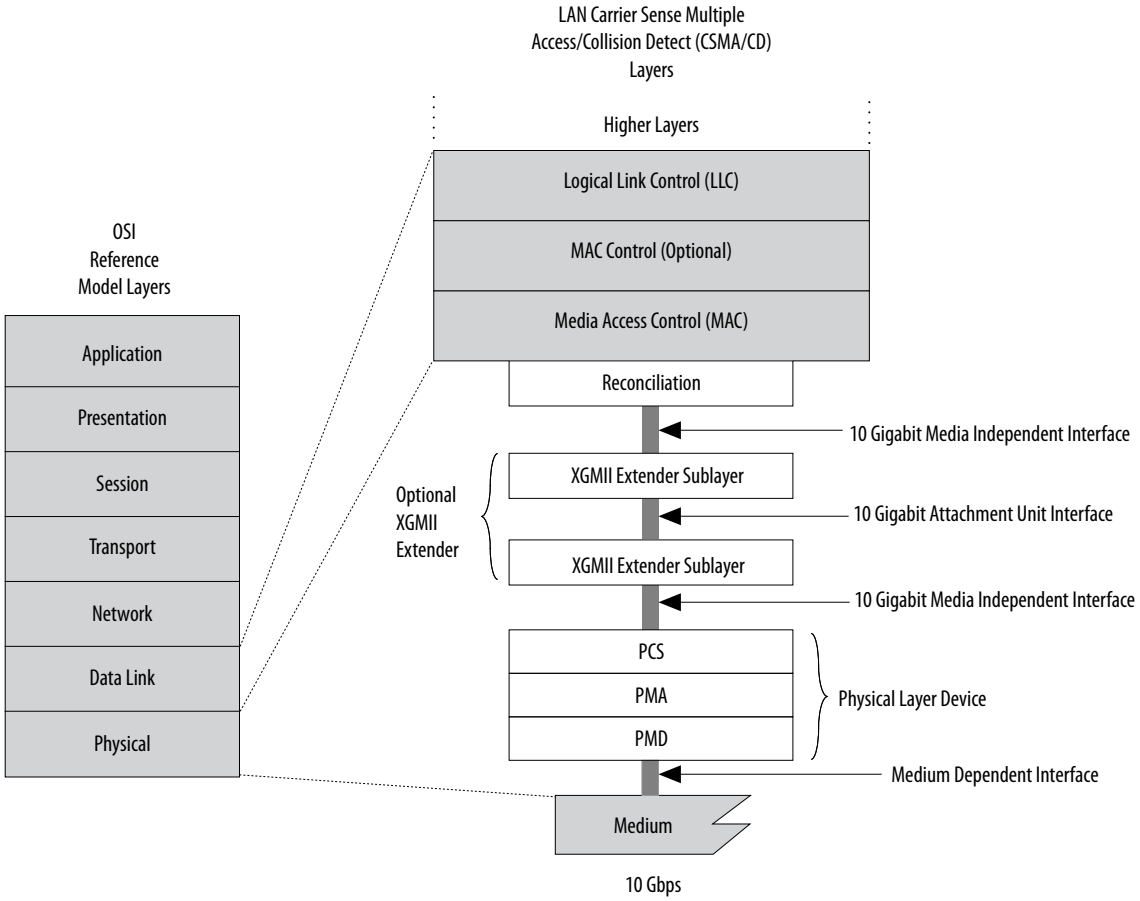
For **PCIe x8 Gen3**, the CMU PLL (transceiver physical channel 4) and the top or bottom ATX PLL of the lower transceiver bank are configured to generate the high-speed serial clock. A total of nine transceiver channels are required to implement PCIe x8 Gen3, including eight data channels and one channel for the CMU PLL. The Quartus II software automatically selects channel 4 in the transceiver bank as the master channel. Channel 4 bonds and drives all the transmitter datapath's clocking and the rate matcher side of the FIFO in the receiver datapaths if rate matching is enabled for the eight data channels. The local clock divider blocks in each data channel generates the parallel clock from this high-speed serial clock and distributes both clocks to the PMA and PCS of that data channel. The master channel in the x8 case is not a data channel.

XAUI

To implement a XAUI link, instantiate the **XAUI PHY IP** core in the IP Catalog, under **Ethernet** in the Interfaces menu. The XAUI PHY IP core implements the XAUI PCS in soft logic.

XAUI is a specific physical layer implementation of the 10 Gigabit Ethernet link defined in the IEEE 802.3ae-2002 specification. The XAUI PHY uses the XGMII interface to connect to the IEEE802.3 MAC and Reconciliation Sublayer (RS). The IEEE 802.3ae-2002 specification requires the XAUI PHY link to support a 10 Gbps data rate at the XGMII interface and four lanes each at 3.125 Gbps at the PMD interface.

Figure 6-42: XAUI and XGMII Layers



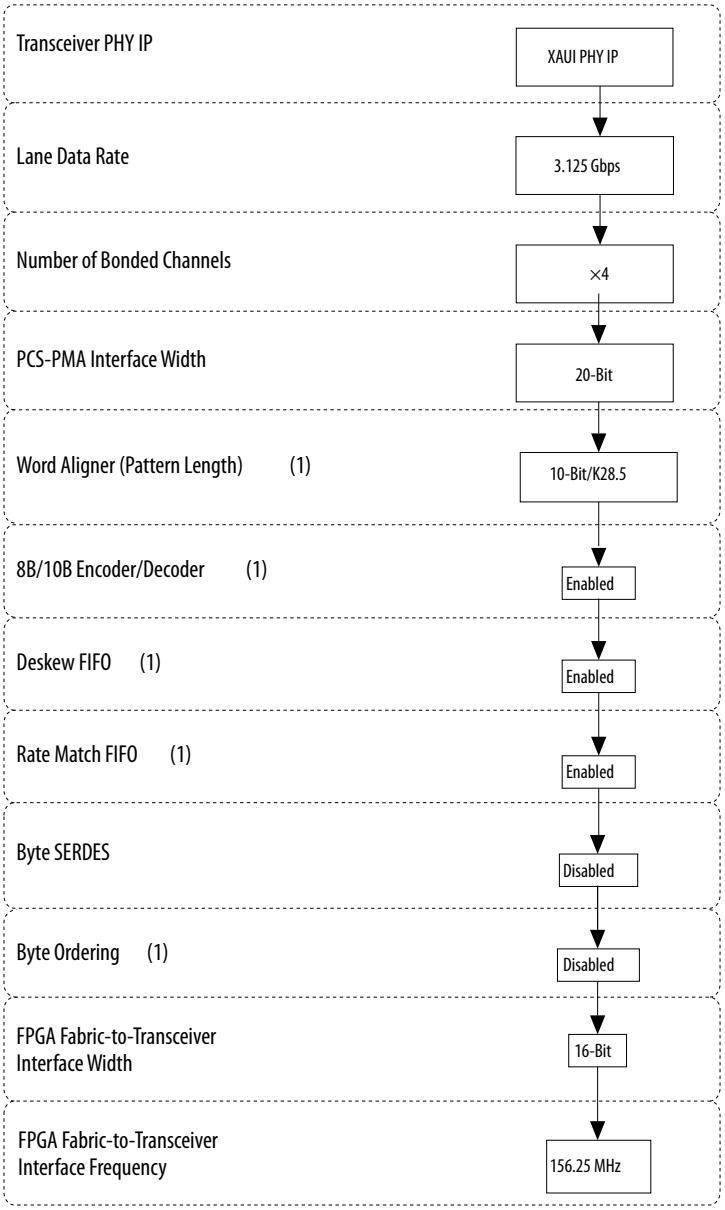
Related Information

Refer to the "XAUI PHY IP Core" chapter in the Altera Transceiver PHY IP Core User Guide.

Transceiver Datapath in a XAUI Configuration

The XAUI PCS is implemented in soft logic inside the FPGA core when using the XAUI PHY IP core. You must ensure that your channel placement is compatible with the soft PCS implementation.

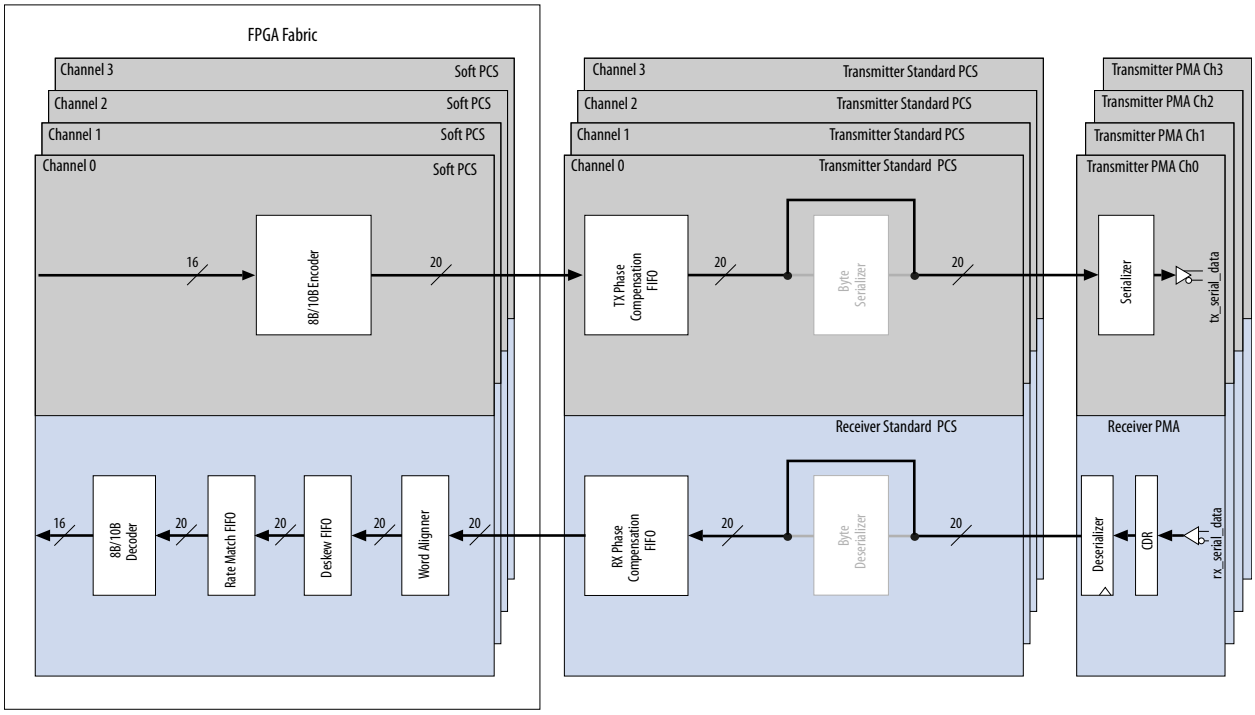
Figure 6-43: XAUI Datapath Configuration



(1) Implemented in soft logic.

Figure 6-44: Transceiver Channel Datapath for XAUI Configuration

Standard PCS in a low latency configuration is used in this configuration. Additionally, a portion of the PCS is implemented in soft logic.



Supported Features

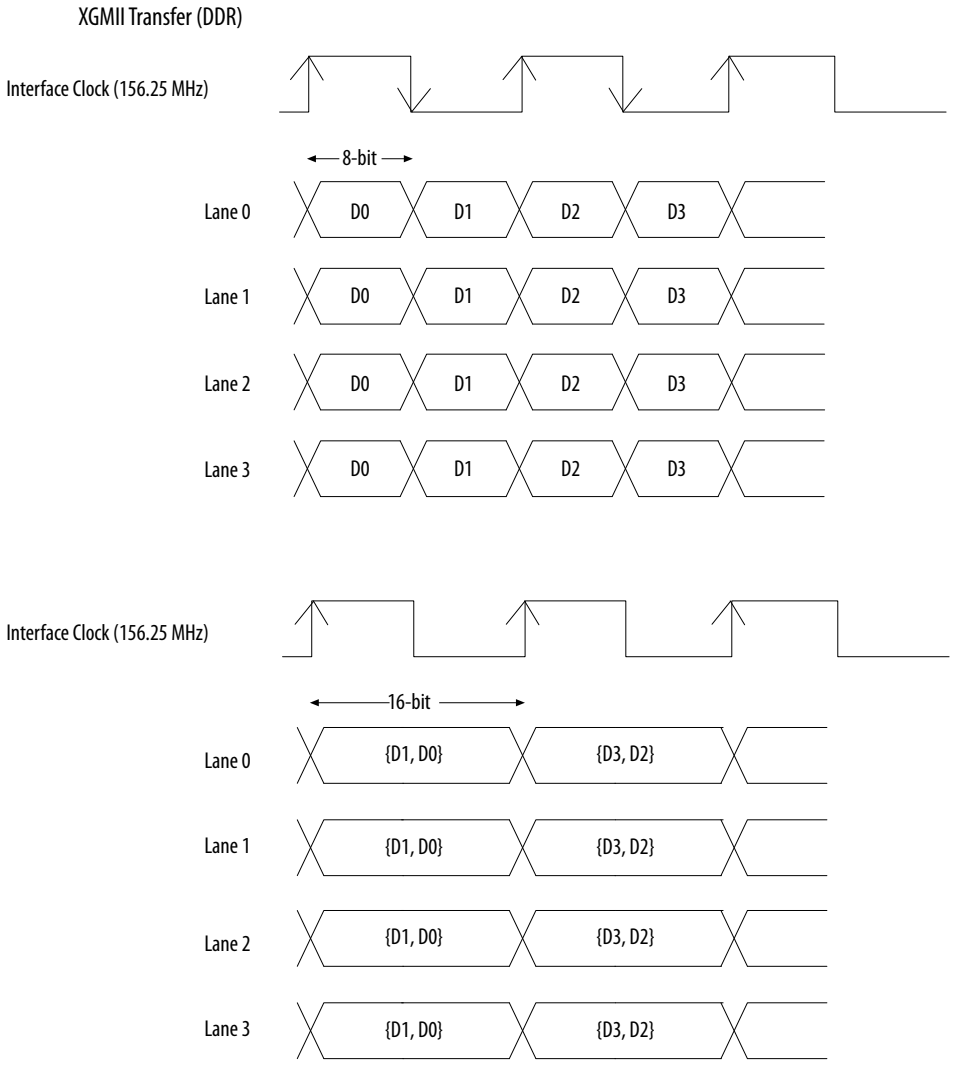
Arria V GZ transceivers support the following features in a XAUI configuration.

64-Bit SDR Interface to the MAC/RS

Clause 46 of the IEEE 802.3-2008 specification defines the XGMII interface between the XAUI PCS and the Ethernet MAC/RS. The specification requires each of the four XAUI lanes to transfer 8-bit data and 1-bit wide control code at both the positive and negative edge (DDR) of the 156.25 MHz interface clock.

Arria V GZ transceivers in a XAUI configuration do not support the XGMII interface to the MAC/RS as defined in IEEE 802.3-2008 specification. Instead, they allow the transferring of 16-bit data and 2-bit control code on each of the four XAUI lanes, only at the positive edge (SDR) of the 156.25 MHz interface clock.

Figure 6-45: Implementation of the XGMII Specification in Arria V GZ Devices



8B/10B Encoding/Decoding

Each of the four lanes in a XAUI configuration support an independent 8B/10B encoder/decoder as specified in Clause 48 of the IEEE802.3-2008 specification. 8B/10B encoding limits the maximum number of consecutive 1s and 0s in the serial data stream to five, thereby ensuring DC balance as well as enough transitions for the receiver CDR to maintain a lock to the incoming data.

The XAUI PHY IP core provides status signals to indicate running disparity as well as the 8B/10B code group error.

Transmitter and Receiver State Machines

In a XAUI configuration, the Arria V GZ transceivers implement the transmitter and receiver state diagrams shown in Figure 48-6 and Figure 48-9 of the IEEE802.3-2008 specification.

In addition to encoding the XGMII data to PCS code groups, in conformance with the 10GBASE-X PCS, the transmitter state diagram performs functions such as converting Idle ||I|| ordered sets into Sync ||K||, Align ||A||, and Skip ||R|| ordered sets.

In addition to decoding the PCS code groups to XGMII data, in conformance with the 10GBASE-X PCS, the receiver state diagram performs functions such as converting Sync ||K||, Align ||A||, and Skip ||R|| ordered sets to Idle ||I|| ordered sets.

Synchronization

The word aligner block in the receiver PCS of each of the four XAUI lanes implements the receiver synchronization state diagram shown in Figure 48-7 of the IEEE802.3-2008 specification.

The XAUI PHY IP core provides a status signal per lane to indicate if the word aligner is synchronized to a valid word boundary.

Deskew

The lane aligner block in the receiver PCS implements the receiver deskew state diagram shown in Figure 48-8 of the IEEE 802.3-2008 specification.

The lane aligner starts the deskew process only after the word aligner block in each of the four XAUI lanes indicates successful synchronization to a valid word boundary.

The XAUI PHY IP core provides a status signal to indicate successful lane deskew in the receiver PCS.

Clock Compensation

The rate match FIFO in the receiver PCS datapath compensates up to ±100 ppm difference between the remote transmitter and the local receiver. It does so by inserting and deleting Skip ||R|| columns, depending on the ppm difference.

The clock compensation operation begins after:

- The word aligner in all four XAUI lanes indicates successful synchronization to a valid word boundary.
- The lane aligner indicates a successful lane deskew.

The rate match FIFO provides status signals to indicate the insertion and deletion of the Skip ||R|| column for clock rate compensation.

Transceiver Clocking and Channel Placement Guidelines

Transceiver Clocking

Figure 6-46: Transceiver Clocking Diagram for XAUI Configuration

One of the two channel PLLs configured as a CMU PLL in a transceiver bank generates the transmitter serial and parallel clocks for the four XAUI channels. The x6 clock line carries the transmitter clocks to the PMA and PCS of each of the four channels.

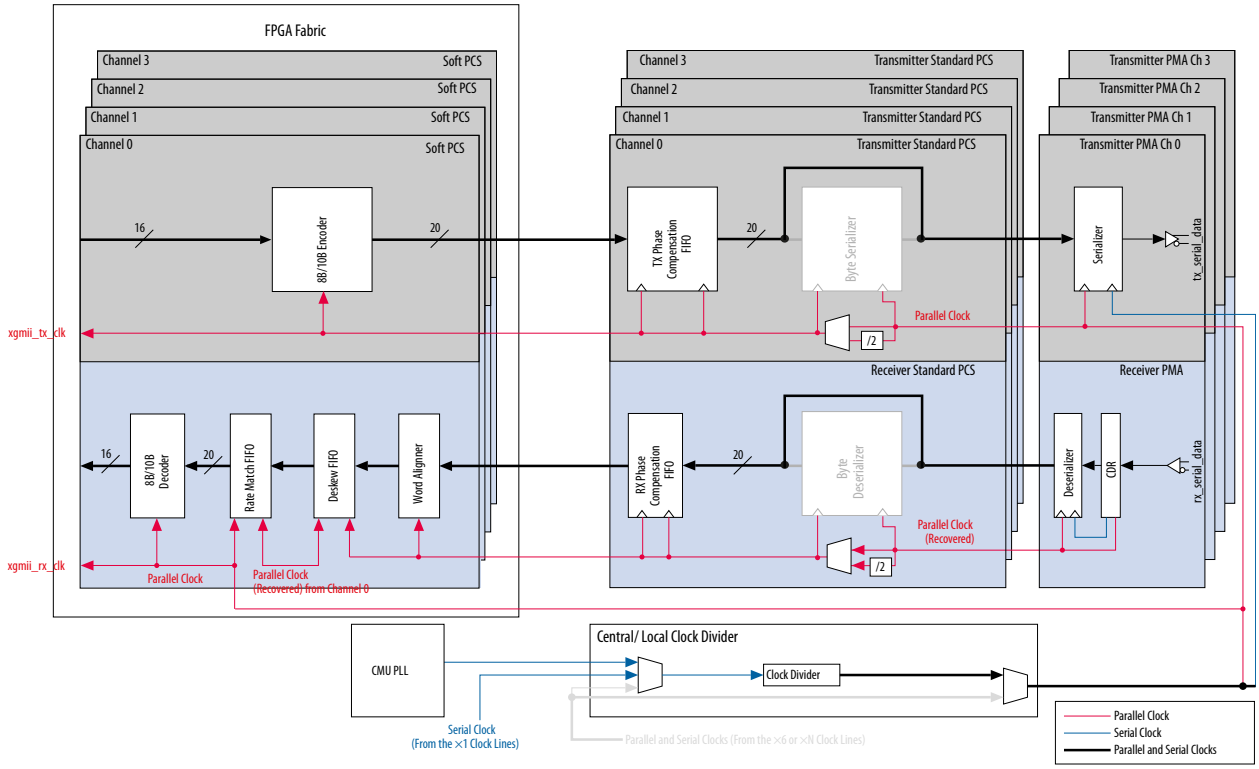


Table 6-8: Input Reference Clock Frequency and Interface Speed Specifications for XAUI Configurations

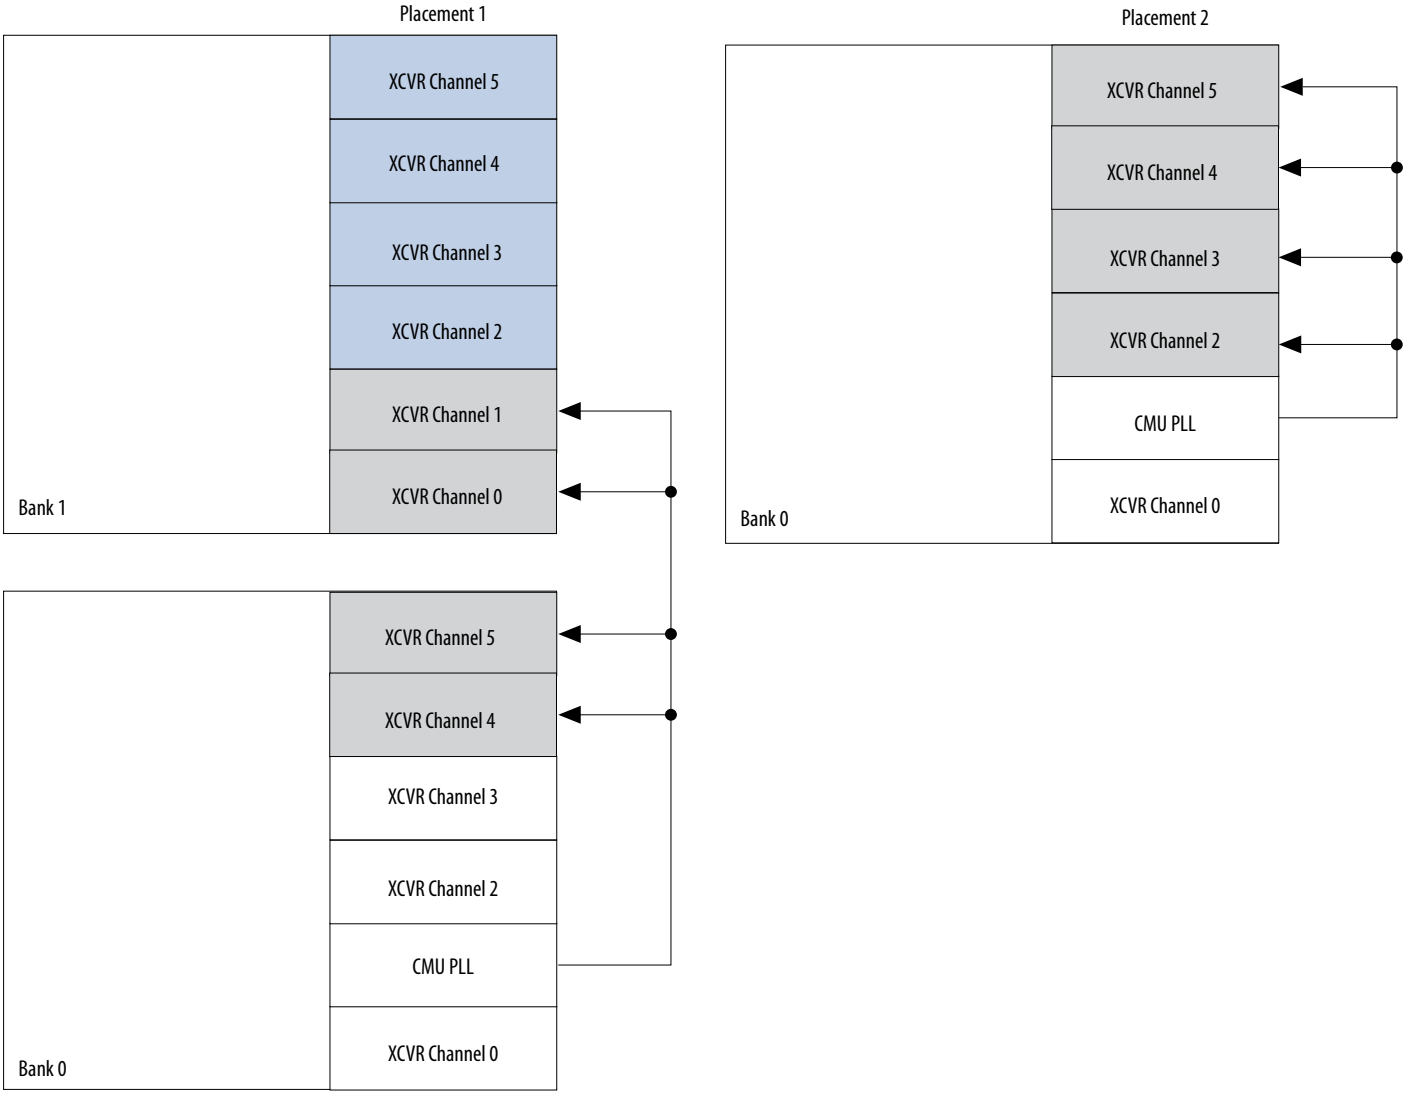
Input Reference Clock Frequency (MHz)	FPGA Fabric-Transceiver Interface Width	FPGA Fabric-Transceiver Interface Frequency (MHz)
156.25	16-bit data, 2-bit control	156.25

Transceiver Channel Placement Guidelines

In the soft PCS implementation of the XAUI configuration, all four channels must be placed continuously. The channels may all be placed in one bank or they may span two banks.

Figure 6-47: Transceiver Channel Placement Guidelines in a XAUI Configuration

Use one of the two allowed channel placements when using either the CMU PLL or the ATX PLL to drive the XAUI link. The Quartus II software implements the XAUI PCS in soft logic.



Related Information

To implement the QSF assignment workaround using the Assignment Editor, refer to the "XAUI PHY IP Core" chapter in the Altera Transceiver PHY IP Core User Guide.

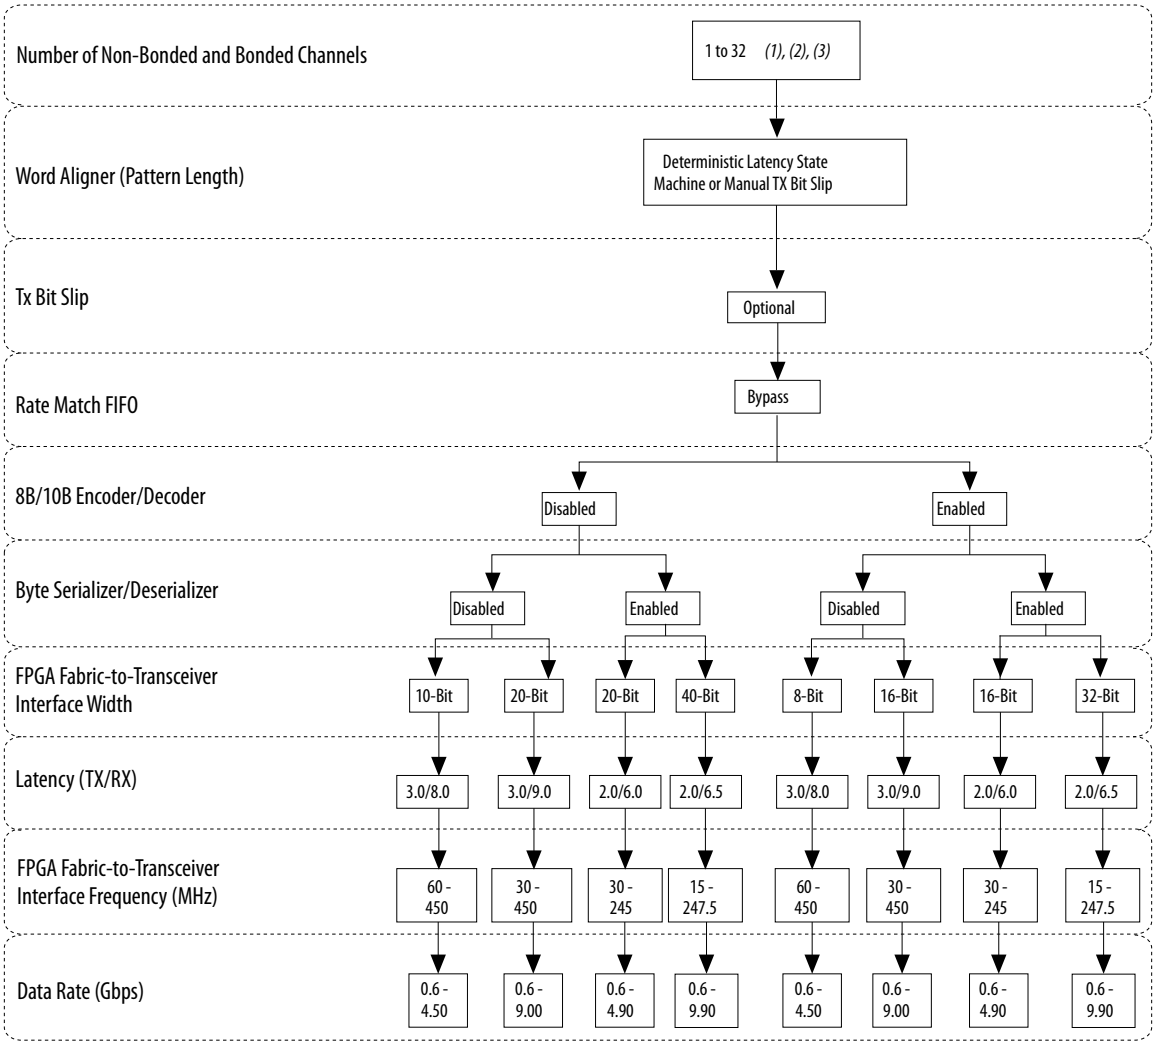
CPRI and OBSAI—Deterministic Latency Protocols

Arria V GZ devices have a deterministic latency option available for use in high-speed serial interfaces such as the Common Public Radio Interface (CPRI) and OBSAI Reference Point 3 (OBSAI RP3). Both CPRI and OBSAI RP3 protocols place stringent requirements on the amount of latency variation that is permissible through a link that implements these protocols.

Transceiver Datapath Configuration

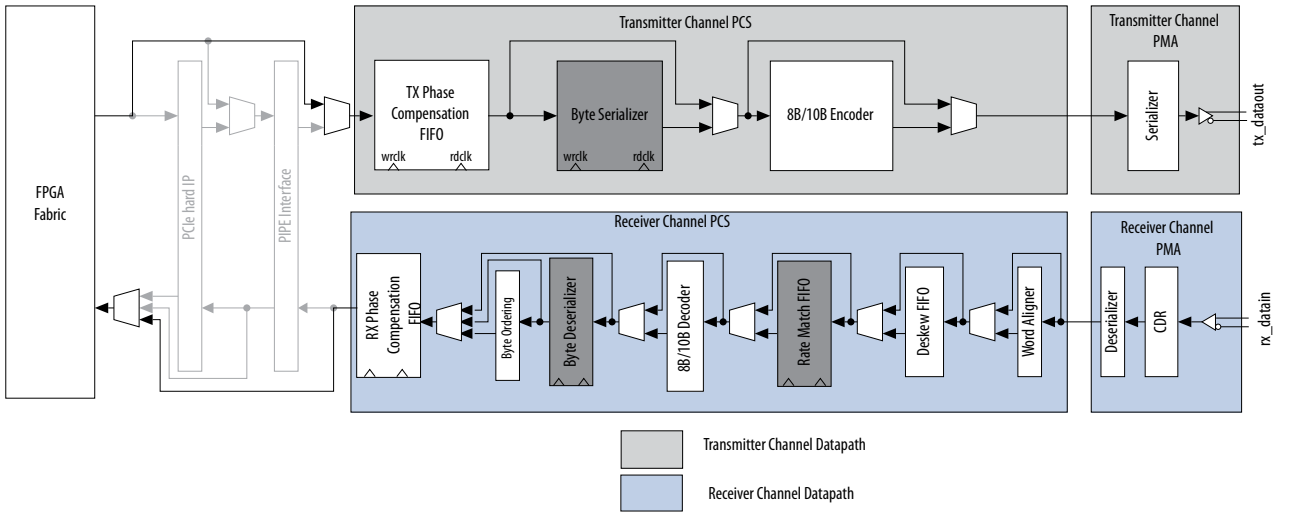
Arria V GZ devices have a number of options available for the deterministic latency datapath configuration.

Figure 6-48: Deterministic Latency Datapath Configuration



Notes:
(1) For xN bonding, the number of bonded channels is up to four using CMU PLL and up to six using ATX PLL, provided the data rate is supported by the CMU PLL and ATX PLL.
(2) Bonding more than six channels requires PLL feedback compensation bonding. PLL feedback compensation bonding requires one PLL per transceiver bank and the PLL reference clock frequency must have the same value as the lane data rate divided by the serialization factor.
(3) The TX-client feedback path to the transmit PLL is only supported in a non-bonded single lane instance.

Figure 6-49: Transceiver Datapath in Deterministic Latency Mode



Phase Compensation FIFO in Register Mode

To remove the latency uncertainty through the receiver's phase compensation FIFO, the receiver and transmitter phase compensation FIFOs are always set to register mode. In register mode, the phase compensation FIFO acts as a register and thereby removes the uncertainty in latency. The latency through the phase compensation FIFO in register mode is one clock cycle.

The following options are available:

- Single-width mode with 8-bit channel width and 8B/10B encoder enabled or 10-bit channel width with 8B/10B disabled
- Double-width mode with 16-bit channel width and 8B/10B encoder enabled or 20-bit channel width with 8B/10B disabled

Channel PLL Feedback

To implement the deterministic latency functional mode, the phase relationship between the low-speed parallel clock and channel PLL input reference clock must be deterministic. A feedback path is enabled to ensure a deterministic relationship between the low-speed parallel clock and channel PLL input reference clock.

To achieve deterministic latency through the transceiver, the reference clock to the channel PLL must be the same as the low-speed parallel clock. For example, if you need to implement a data rate of 1.2288 Gbps for the CPRI protocol, which places stringent requirements on the amount of latency variation, you must choose a reference clock of 122.88 MHz to allow the usage of a feedback path from the channel PLL. This feedback path reduces the variations in latency.

When you select this option, provide an input reference clock to the channel PLL that is of the same frequency as the low-speed parallel clock.

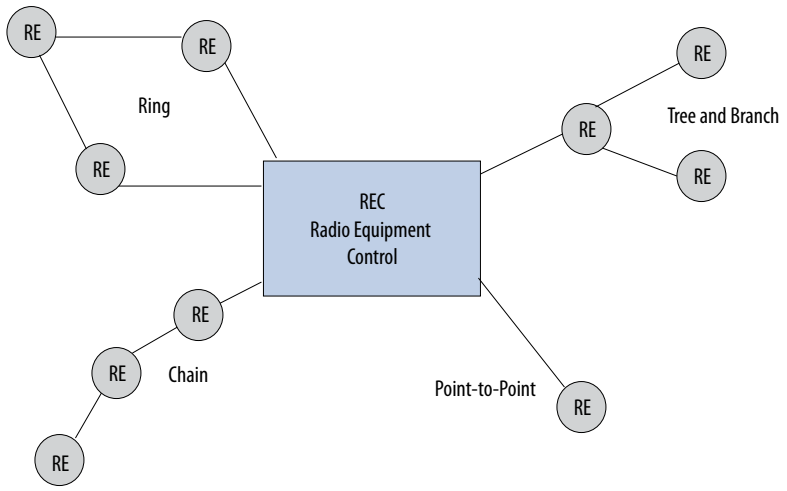
CPRI and OBSAI

Use the deterministic latency functional mode to implement protocols such as CPRI and OBSAI.

The CPRI interface defines a digital point-to-point interface between the Radio Equipment Control (REC) and the Radio Equipment (RE), allowing flexibility in either co-locating the REC and the RE, or a remote location of the RE.

Figure 6-50: CPRI Topologies

In most cases, CPRI links are between REC and RE modules or between two RE modules in a chain configuration.



If the destination for the high-speed serial data that leaves the REC is the first RE, it is a single-hop connection. If the serial data from the REC must traverse through multiple REs before reaching the destination RE, it is a multi-hop connection.

Remotely locating the RF transceiver from the main base station introduces a complexity with overall system delay. The CPRI specification requires that the accuracy of measurement of roundtrip delay on single-hop and multi-hop connections be within ±16.276 ns to properly estimate the cable delay.

For a single-hop system, this allows a variation in roundtrip delay of up to ±16.276 ns. However, for multi-hop systems, the allowed delay variation is divided among the number of hops in the connection—typically, equal to ±16.276 ns/(the number of hops) but not always equally divided among the hops.

Deterministic latency on a CPRI link also enables highly accurate triangulation of the location of the caller.

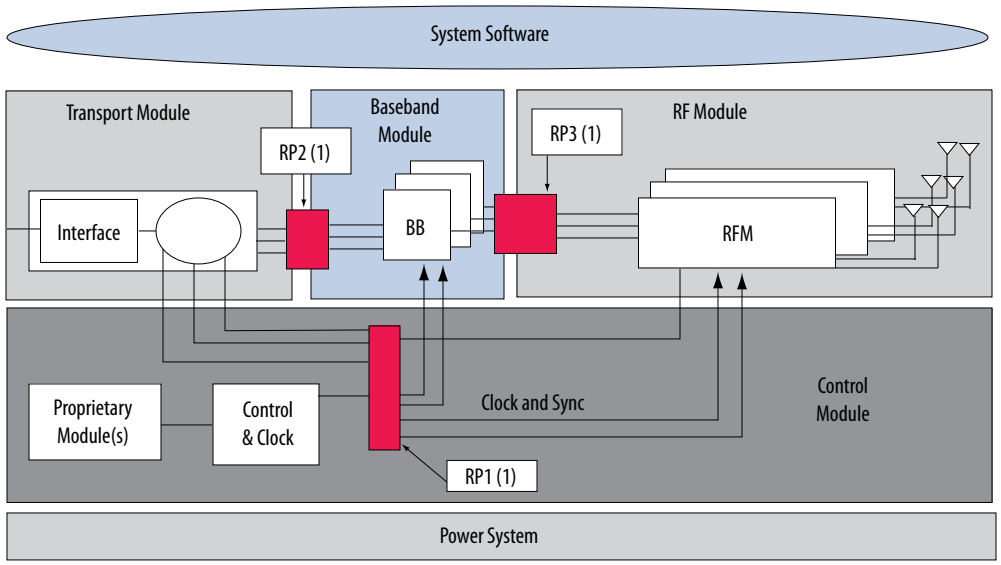
OBSAI was established by several OEMs to develop a set of specifications that can be used for configuring and connecting common modules into base transceiver stations (BTS).

The BTS has four main modules:

- Radio frequency (RF)
- Baseband
- Control
- Transport

In a typical BTS, the radio frequency module (RFM) receives signals using portable devices and converts the signals to digital data. The baseband module processes the encoded signal and brings it back to the baseband before transmitting it to the terrestrial network using the transport module. A control module maintains the coordination between these three functions.

Figure 6-51: Example of the OBSAI BTS Architecture



(1) RP = Reference Point

Using the deterministic latency option, you can implement the CPRI data rates in the following modes:

- Single-width mode—with 8/10-bit channel width
- Double-width mode—with 16/20-bit channel width

Table 6-9: Sample Channel Width Options for Supported Serial Data Rates

Serial Data Rate (Mbps)	Channel Width (FPGA-PCS Fabric)			
	Single Width		Double-Width	
	8-Bit	16-Bit	16-Bit	32-Bit
614.4	Yes	Yes	—	—
1228.8	Yes	Yes	Yes	Yes
2457.6	—	Yes	Yes	Yes
3072	—	Yes	Yes	Yes
4915.2	—	—	—	Yes
6144	—	—	—	Yes
9800 (38)(39)	—	—	—	Yes

Related Information

For more information, refer to the Deterministic Latency PHY IP Core chapter in the Altera Transceiver PHY IP Core User Guide.

(38) The Arria V GZ Standard PCS can support up to 9.9 Gbps datarates in Deterministic Latency configuration or up to 9.8 Gbps in Custom and Low Latency configurations.
(39) Applicable to C3 and I3L speed grades only.

Transceiver Configurations

Arria V GZ transceivers offer both standard PCS and 10G PCS configurations. These configurations allow you to modify, enable, or disable blocks based on your protocol requirements. This flexibility allows you to implement various protocols through the Custom, Low Latency, and Native PHY IPs.

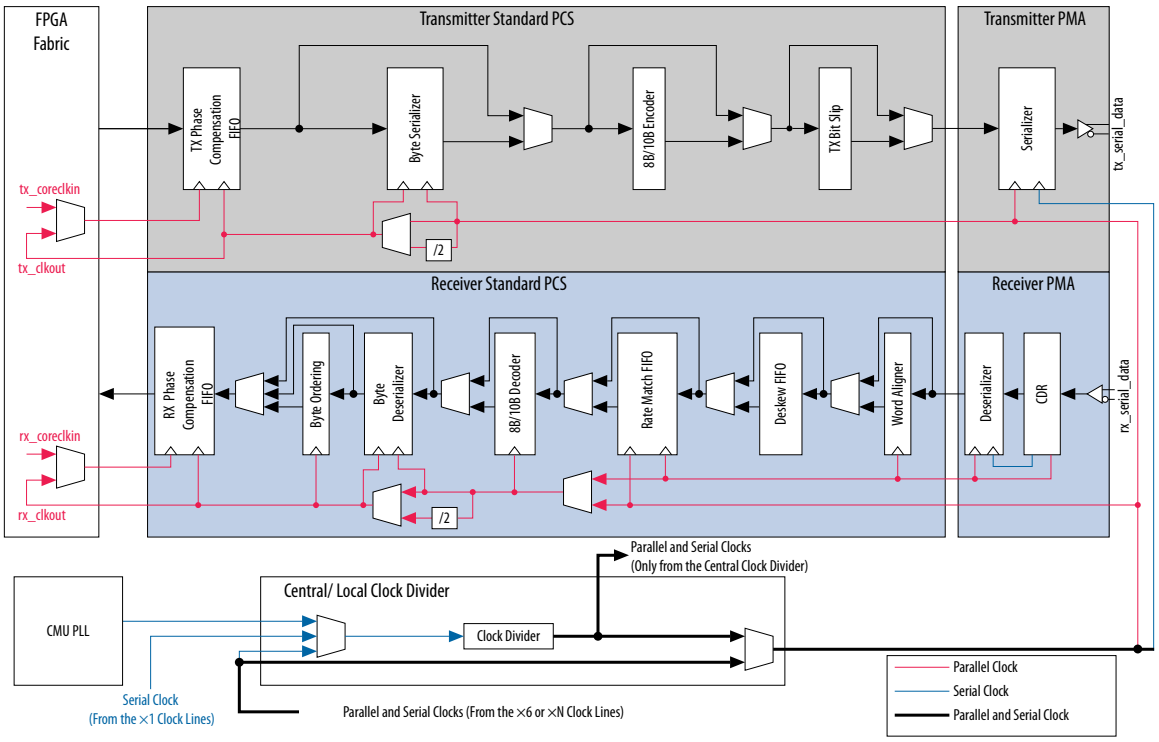
Standard PCS Configurations—Custom Datapath

Use the Custom PHY IP to enable the standard PCS in custom datapath. To implement a Custom PHY link, instantiate the **Custom PHY IP** in the IP Catalog, under **Transceiver PHY** in the Interfaces menu. Define your custom datapath configurations by selecting the blocks to use and the appropriate data width.

The custom datapath consists of the following blocks:

- 8B/10B encoder and decoder
- Word aligner
- Deskew FIFO
- Rate match FIFO (clock rate compensation FIFO)
- Byte ordering block
- Phase compensation FIFO
- Byte serializer and deserializer
- Transmit bit slip

Figure 6-52: Standard PCS Custom Datapath and Clocking



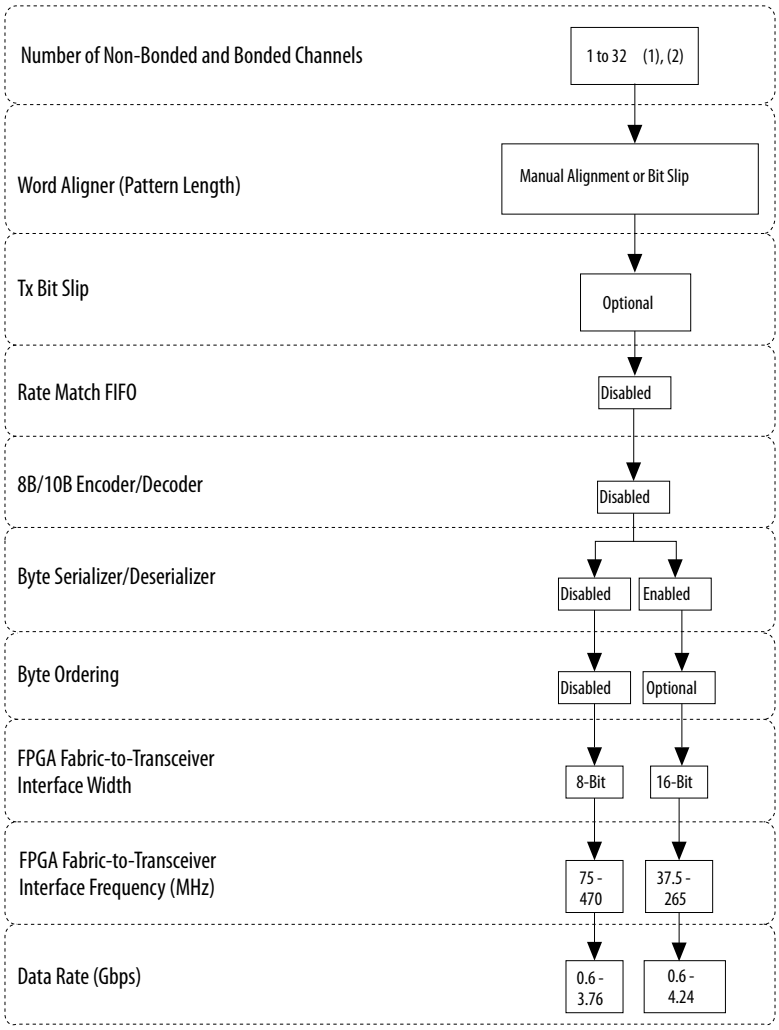
You can divide the custom datapath into two configurations based on the FPGA fabric-transceiver interface width and the PMA-PCS interface width (serialization factor):

- **Custom 8/10-bit-width**—the PCS-PMA interface width is in 8-bit or 10-bit mode for lower data rates.
- **Custom 16/20-bit-width**—the PCS-PMA interface width is in 16-bit or 20-bit mode for higher data rates.

Table 6-10: PCS-PMA Interface Widths and Supported Data Rates

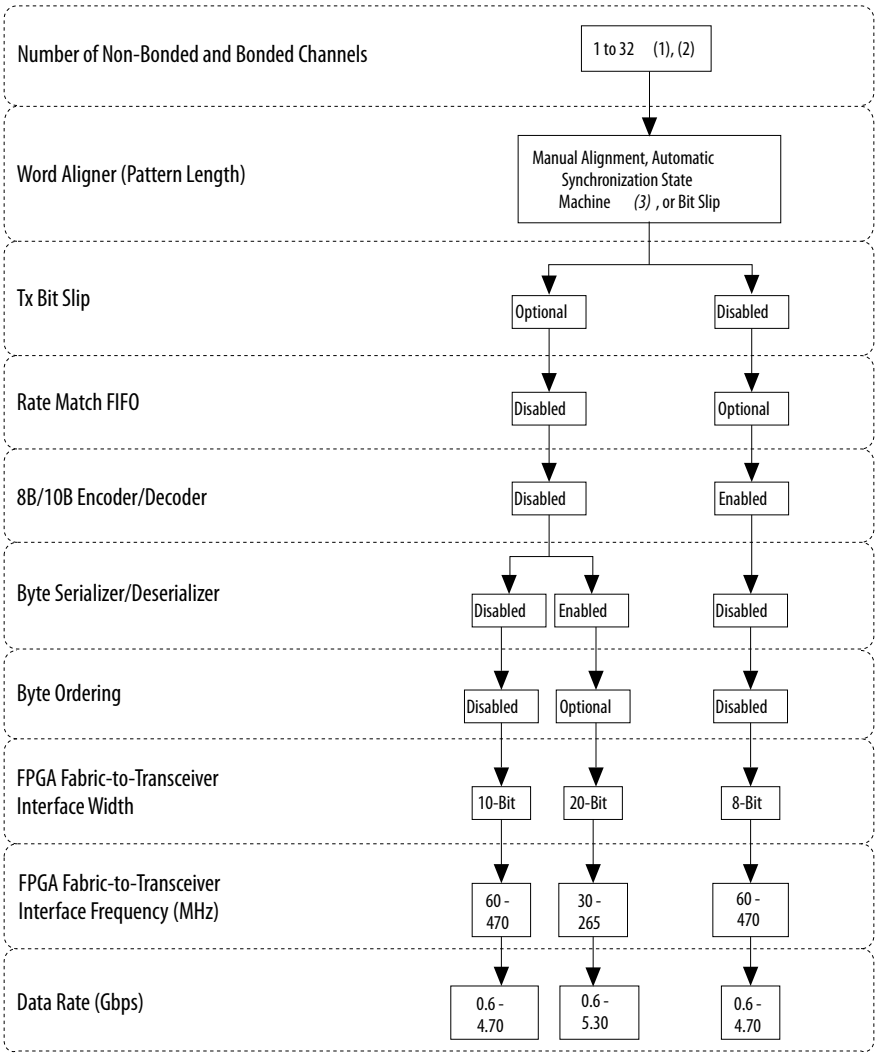
PCS-PMA Interface Width	Supported Data Rate Range PMA
Custom 8-bit width	600 Mbps to 4.24 Gbps
Custom 10-bit width	600 Mbps to 5.30 Gbps
Custom 16-bit width	600 Mbps to 7.84 Gbps
Custom 20-bit width	600 Mbps to 9.80 Gbps

Figure 6-53: Standard PCS Custom 8-Bit PMA-PCS Interface Width



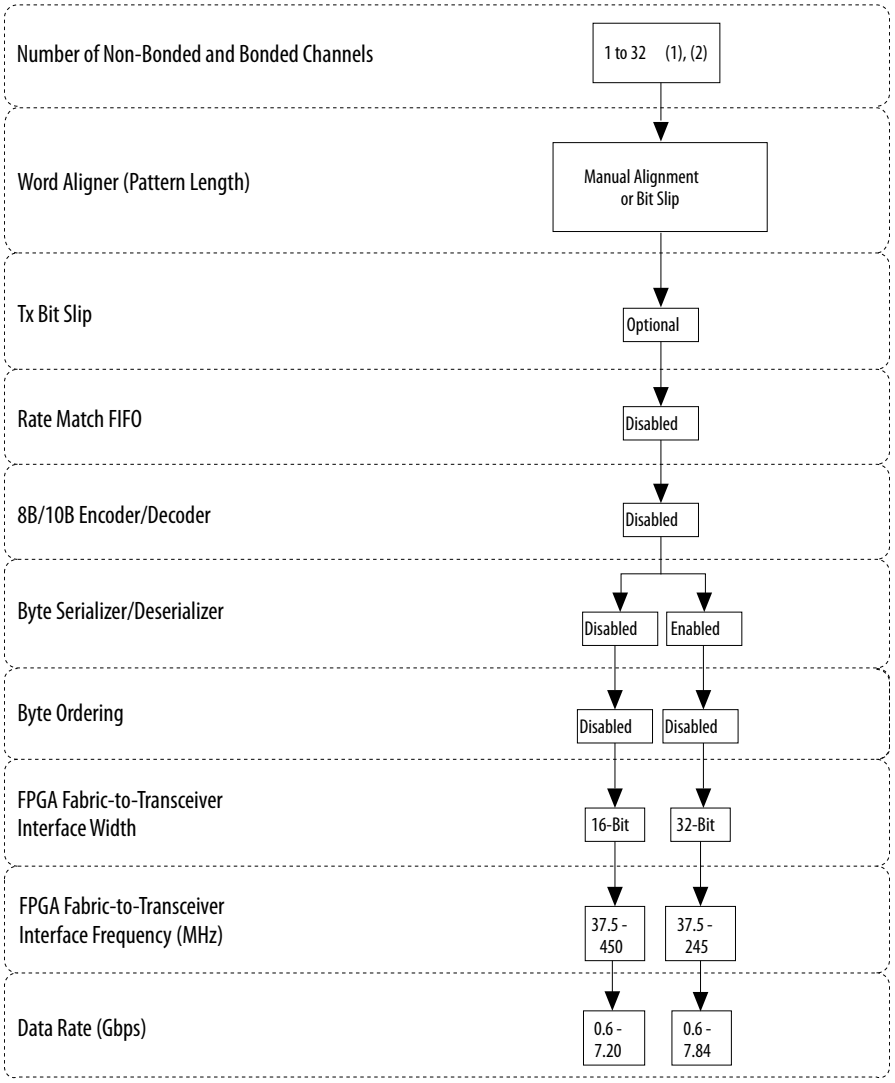
Notes:
(1) For xN bonding, the number of bonded channels is up to four using CMU PLL and up to six using ATX PLL, provided the data rate is supported by the CMU PLL and ATX PLL.
(2) Bonding more than six channels requires PLL feedback compensation bonding. PLL feedback compensation bonding requires one PLL per transceiver bank and the PLL reference clock frequency must have the same value as the lane data rate divided by the serialization factor.

Figure 6-54: Standard PCS Custom 10-Bit PMA-PCS Interface Width



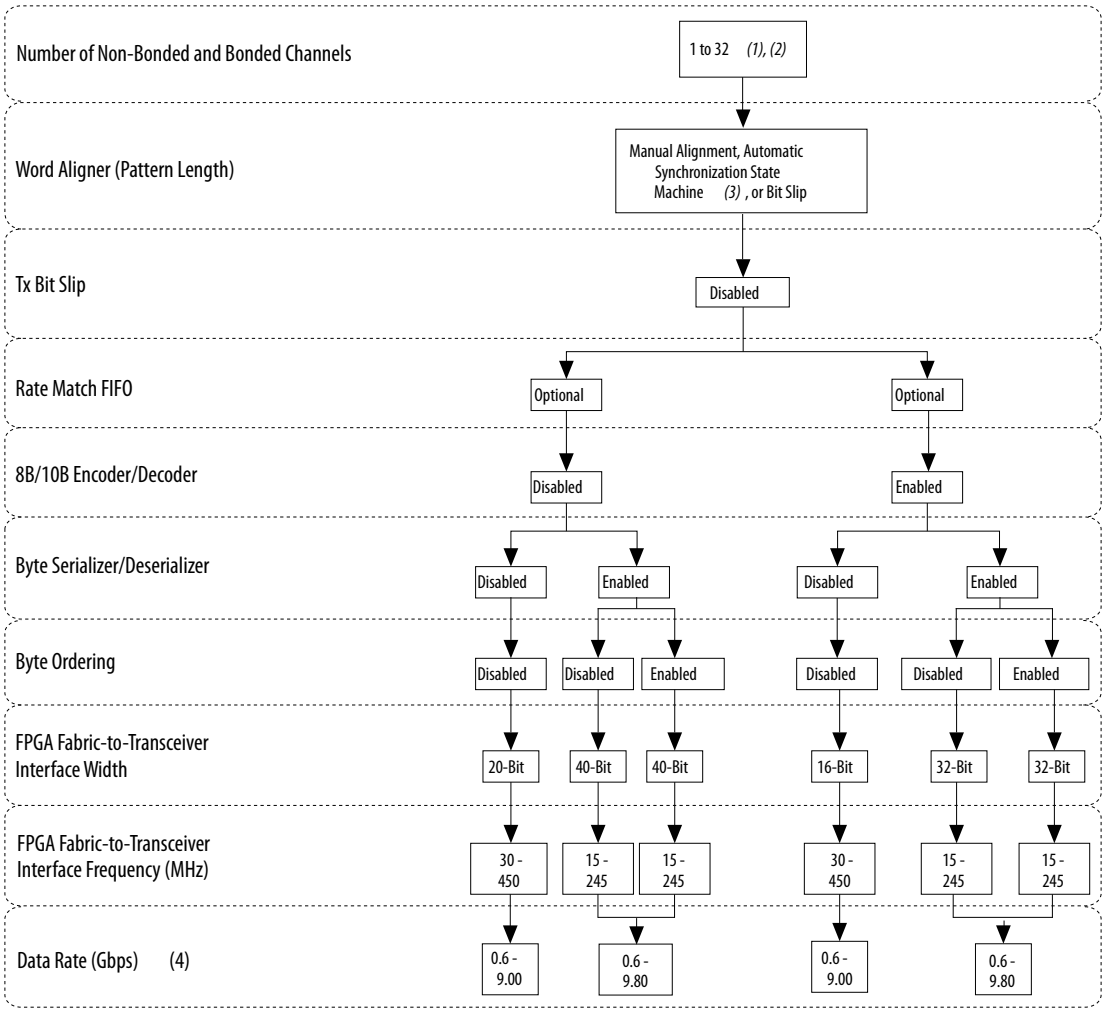
Notes:
(1) For xN bonding, the number of bonded channels is up to four using CMU PLL and up to six using ATX PLL, provided the data rate is supported by the CMU PLL and ATX PLL.
(2) Bonding more than six channels requires PLL feedback compensation bonding. PLL feedback compensation bonding requires one PLL per transceiver bank and the PLL reference clock frequency must have the same value as the lane data rate divided by the serialization factor.
(3) Automatic Synchronization State Machine requires enabling the 8B/10B Encoder/Decoder.

Figure 6-55: Standard PCS Custom 16-Bit PMA-PCS Interface Width



Notes:
(1) For xN bonding, the number of bonded channels is up to four using CMU PLL and up to six using ATX PLL, provided the data rate is supported by the CMU PLL and ATX PLL.
(2) Bonding more than six channels requires PLL feedback compensation bonding. PLL feedback compensation bonding requires one PLL per transceiver bank and the PLL reference clock frequency must have the same value as the lane data rate divided by the serialization factor.

Figure 6-56: Standard PCS Custom 20-Bit PMA-PCS Interface Width



Notes:
(1) For xN bonding, the number of bonded channels is up to four using CMU PLL and up to six using ATX PLL, provided the data rate is supported by the CMU PLL and ATX PLL.
(2) Bonding more than six channels requires PLL feedback compensation bonding. PLL feedback compensation bonding requires one PLL per transceiver bank and the PLL reference clock frequency must have the same value as the lane data rate divided by the serialization factor.
(3) Automatic Synchronization State Machine requires enabling the 8B/10B Encoder/Decoder.
(4) The maximum data rate specification is valid only for the -2 (fastest) speed grade devices. For data rate specifications for other speed grades, refer to the device datasheet for that device.

Related Information

- **Refer to the "PCS Architecture" section in the Transceiver Architecture in Arria V Devices chapter**
- **For information about the maximum data rate for a certain speed grade, refer to the Arria V Device Datasheet**
- **Refer to the "Custom PHY IP Core" chapter in the Altera Transceiver PHY IP Core User Guide**

Standard PCS Configurations—Low Latency Datapath

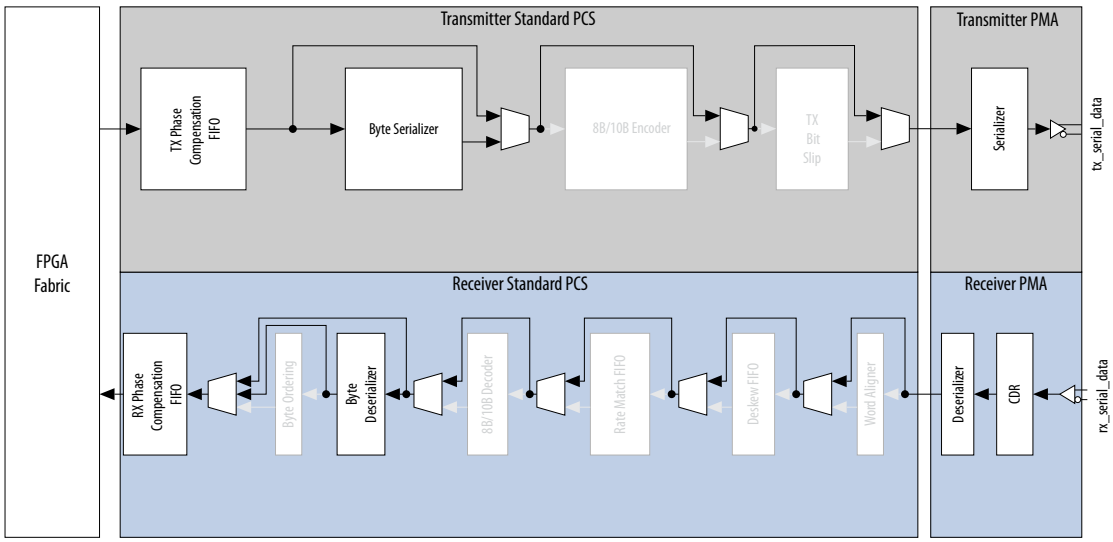
A low latency datapath bypasses much of the standard PCS, allowing more design control in the FPGA fabric. Use the Low Latency PHY IP to enable the standard PCS in a low latency datapath.

To implement a Low Latency PHY link, instantiate the **Low Latency PHY IP** in the IP Catalog, under **Transceiver PHY** in the Interfaces menu. In the Low Latency GUI under the **General** tab, select **Standard** on the **Datapath type** field.

The standard PCS can be used in a low latency datapath that contains only the following blocks:

- Phase compensation FIFO
- Byte serializer and deserializer

Figure 6-57: Standard PCS Low Latency Datapath



You can divide the low latency datapath into two configurations based on the FPGA fabric-transceiver interface width and the PMA-PCS interface width (serialization factor):

- **Low latency 8/10-bit-width**—the PCS-PMA interface width is in 8-bit or 10-bit mode for lower data rates.
- **Low latency 16/20-bit-width**—the PCS-PMA interface width is in 16-bit or 20-bit mode for higher data rates.

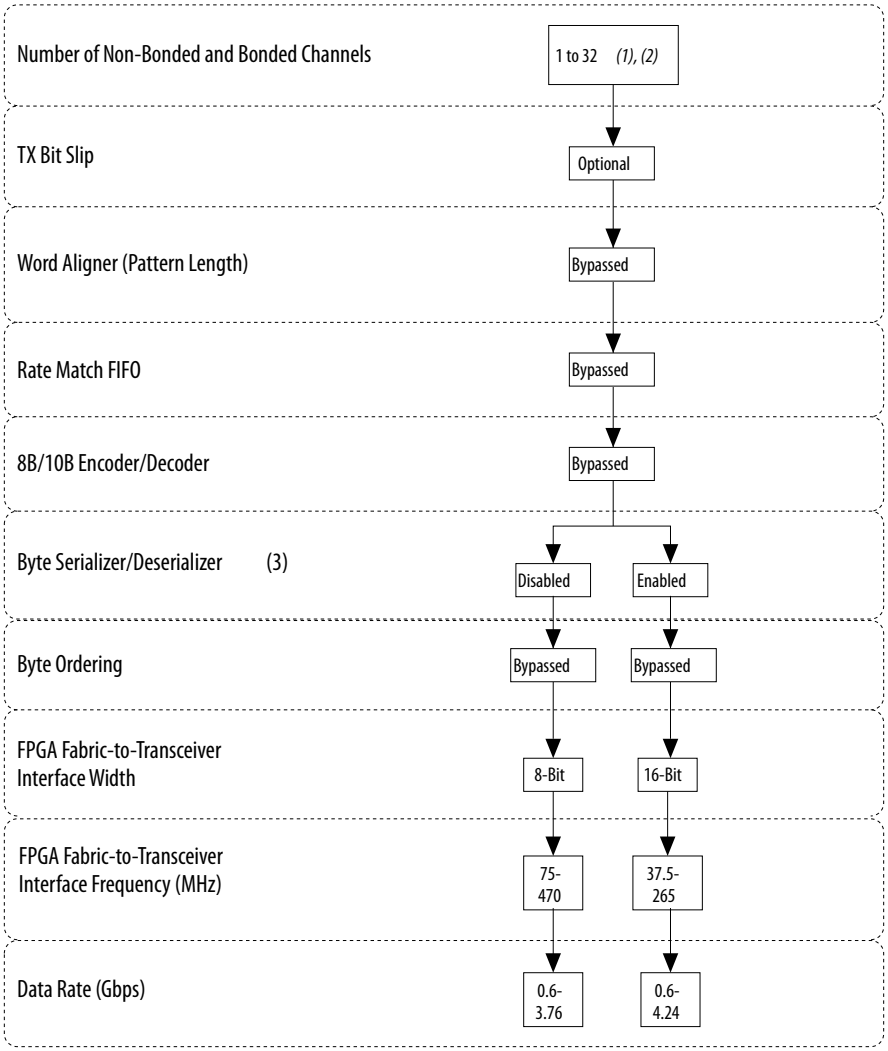
Table 6-11: PCS-PMA Interface Widths and Data Rates

Low Latency PHY IP Core	Supported Data Rate Range PMA
Low Latency 8-bit width	600 Mbps to 4.24 Gbps
Low Latency 10-bit width	600 Mbps to 5.30 Gbps
Low Latency 16-bit width	600 Mbps to 7.84 Gbps
Low Latency 20-bit width	600 Mbps to 9.80 Gbps

In the low latency datapath, the TX and RX phase compensation FIFOs are always enabled. Depending on the targeted data rate, you may bypass the byte serializer and deserializer blocks.

Figure 6-58: Standard PCS Low Latency 8-Bit PMA-PCS Interface Width

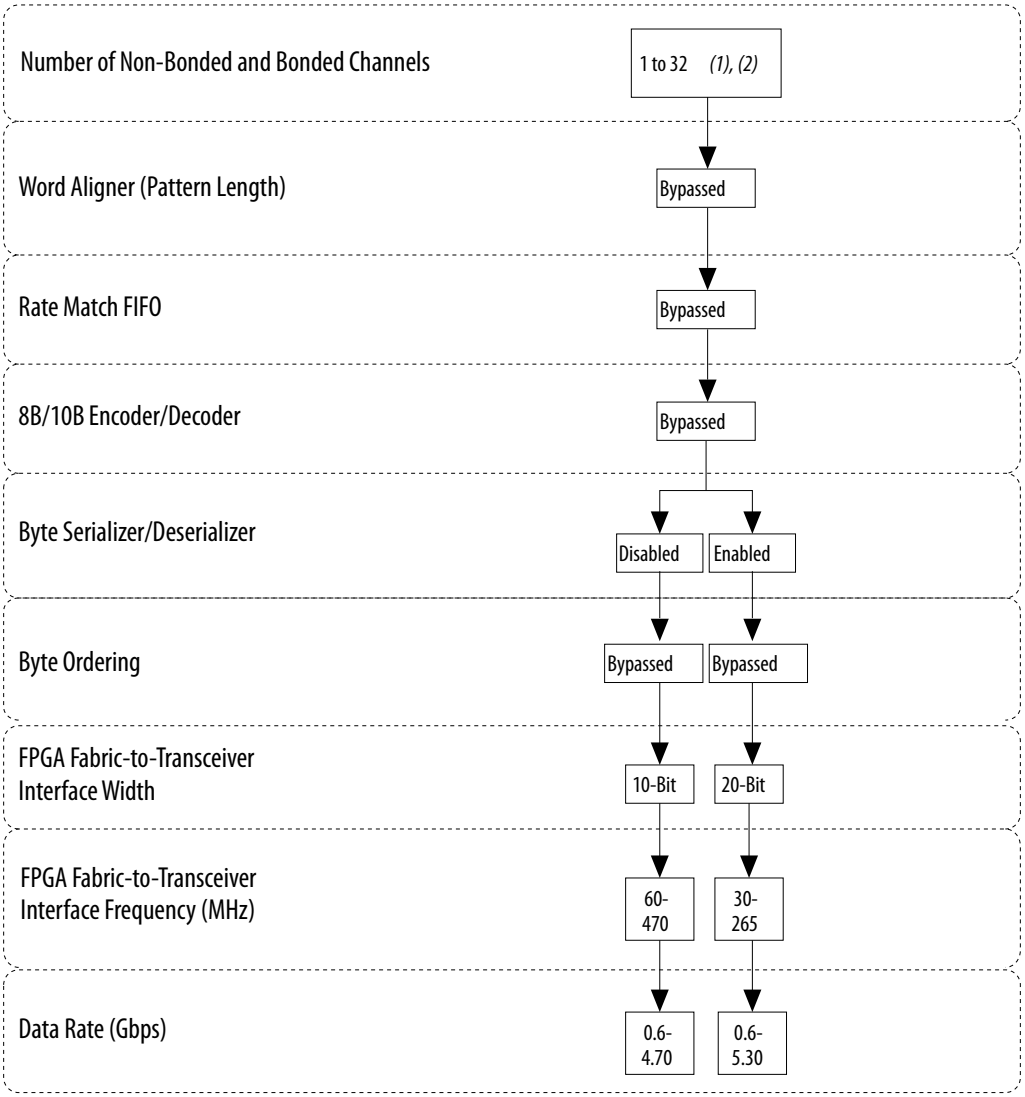
Shows the available options for the standard PCS low latency 8-bit PMA-PCS interface width. The blocks shown as "Disabled" are not used but incur latency. The blocks shown as "Bypassed" are not used and do not incur any latency. The maximum frequencies are for the fastest devices.



Notes:
(1) For xN bonding, the number of bonded channels is up to four using CMU PLL and up to six using ATX PLL, provided the data rate is supported by the CMU PLL and ATX PLL.
(2) Bonding more than six channels requires PLL feedback compensation bonding. PLL feedback compensation bonding requires one PLL per transceiver bank and the PLL reference clock frequency must have the same value as the lane data rate divided by the serialization factor.
(3) The Quartus II software selects whether the byte serializer/deserializer is enabled or disabled based on the datapath width.

Figure 6-59: Standard PCS Low Latency 10-Bit PMA-PCS Interface Width

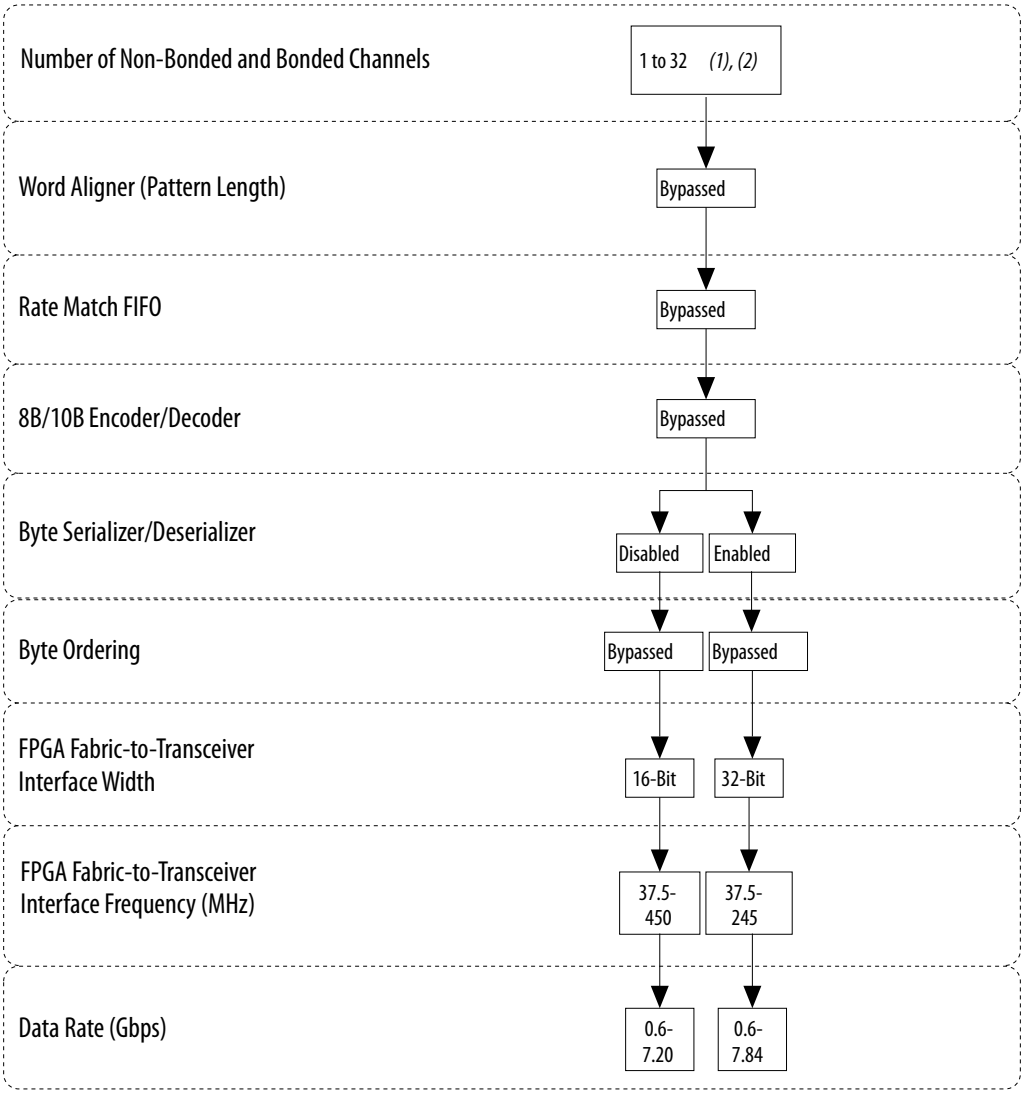
Shows the available options for the standard PCS low latency 10-bit PMA-PCS interface width. The blocks shown as "Disabled" are not used but incur latency. The blocks shown as "Bypassed" are not used and do not incur any latency. The maximum frequencies are for the fastest devices.



Notes:
(1) For xN bonding, the number of bonded channels is up to four using CMU PLL and up to six using ATX PLL, provided the data rate is supported by the CMU PLL and ATX PLL.
(2) Bonding more than six channels requires PLL feedback compensation bonding. PLL feedback compensation bonding requires one PLL per transceiver bank and the PLL reference clock frequency must have the same value as the lane data rate divided by the serialization factor.

Figure 6-60: Standard PCS Low Latency 16-Bit PMA-PCS Interface Width

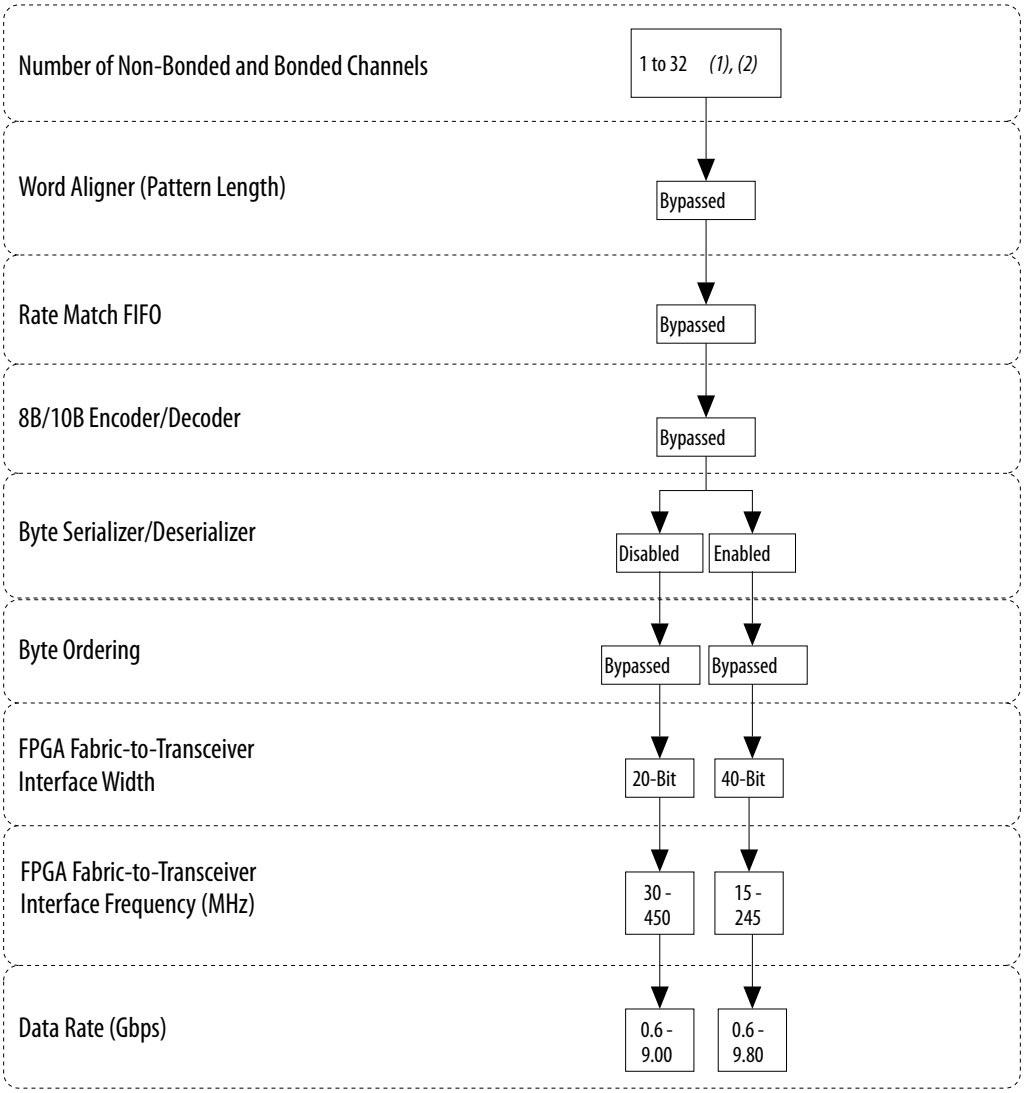
Shows the available options for the standard PCS low latency 16-bit PMA-PCS interface width. The blocks shown as "Disabled" are not used but incur latency. The blocks shown as "Bypassed" are not used and do not incur any latency. The maximum frequencies are for the fastest devices.



Notes:
(1) For xN bonding, the number of bonded channels is up to four using CMU PLL and up to six using ATX PLL, provided the data rate is supported by the CMU PLL and ATX PLL.
(2) Bonding more than six channels requires PLL feedback compensation bonding. PLL feedback compensation bonding requires one PLL per transceiver bank and the PLL reference clock frequency must have the same value as the lane data rate divided by the serialization factor.

Figure 6-61: Standard PCS Low Latency 20-Bit PMA-PCS Interface Width

Shows the available options for the standard PCS low latency 20-bit PMA-PCS interface width. The blocks shown as "Disabled" are not used but incur latency. The blocks shown as "Bypassed" are not used and do not incur any latency. The maximum frequencies are for the fastest devices.



Notes:
(1) For xN bonding, the number of bonded channels is up to four using CMU PLL and up to six using ATX PLL, provided the data rate is supported by the CMU PLL and ATX PLL.
(2) Bonding more than six channels requires PLL feedback compensation bonding. PLL feedback compensation bonding requires one PLL per transceiver bank and the PLL reference clock frequency must have the same value as the lane data rate divided by the serialization factor.

Related Information

- **Refer to the "PCS Architecture" section in the Transceiver Architecture in Arria V Devices chapter**
- **For information about the maximum data rate for a certain speed grade, refer to the Arria V Device Datasheet**
- **Refer to the "Low Latency PHY IP Core" chapter in the Altera Transceiver PHY IP Core User Guide**

Transceiver Channel Placement Guidelines

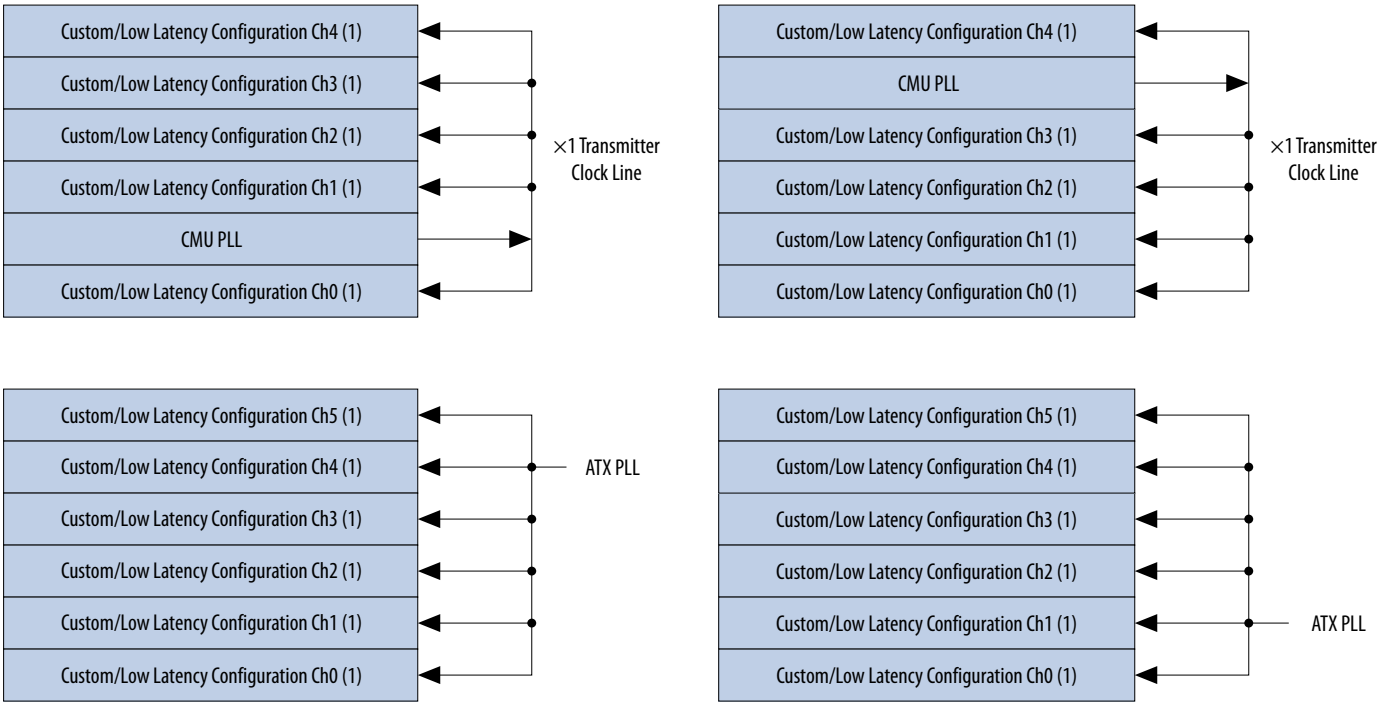
You can use CMU PLLs or ATX PLLs in non-bonded and bonded configurations.

Arria V GZ devices allow the placement of up to five channels when a CMU PLL is used or up to six channels when an ATX PLL is used in a non-bonded configuration within the same transceiver bank:

- Custom PHY IP with standard PCS datapath configuration
- Low Latency PHY IP with Standard PCS or 10G PCS (same data rate) in low latency datapath configuration

Figure 6-62: Non-Bonded Channel Placement Guidelines with Standard and 10G PCS in Custom and Low Latency Datapath Configurations

All channels are assumed to contain a transmitter and receiver.

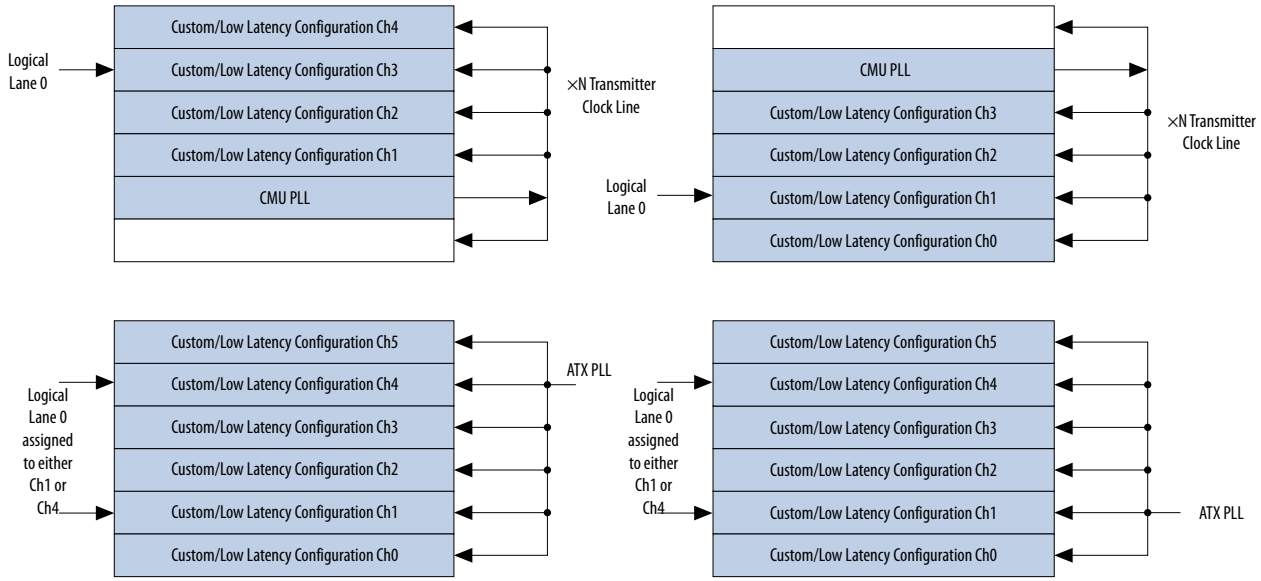


Arria V GZ devices allow the placement of up to four channels when a CMU PLL is used or up to six channels when an ATX PLL is used in a bonded configuration within the same transceiver bank:

- Custom PHY IP with standard PCS datapath configuration
- Low Latency PHY IP with Standard PCS or 10G PCS (same data rate) in low latency datapath configuration

The xN bonding method requires Logical Lane 0 be placed at either transceiver physical channel 1 or 4 within a transceiver bank. The PLL feedback compensation bonding method does not have a Logical Lane 0 assignment requirement and must be used when more than one transceiver bank is needed. However, PLL feedback compensation bonding requires the use of one PLL per transceiver bank.

Figure 6-63: Bonded Channel Placement Guidelines with Standard and 10G PCS in Custom and Low Latency Datapath Configurations



10G PCS Configurations

The Low Latency PHY IP can also configure 10G PCS in the low latency datapath.

To implement a Low Latency PHY link with the 10G PCS, instantiate the **Low Latency PHY IP** in the IP Catalog, under **Transceiver PHY** in the Interfaces menu. In the Low Latency GUI under the **General** tab, select **10G** on the **Datapath type** field.

A Low Latency PHY IP core with the 10G PCS is available for 32-bit, 40-bit, 50-bit, 64-bit, or 66-bit PCS data width configurations.

Figure 6-64: 10G PCS Low Latency Configuration Datapath

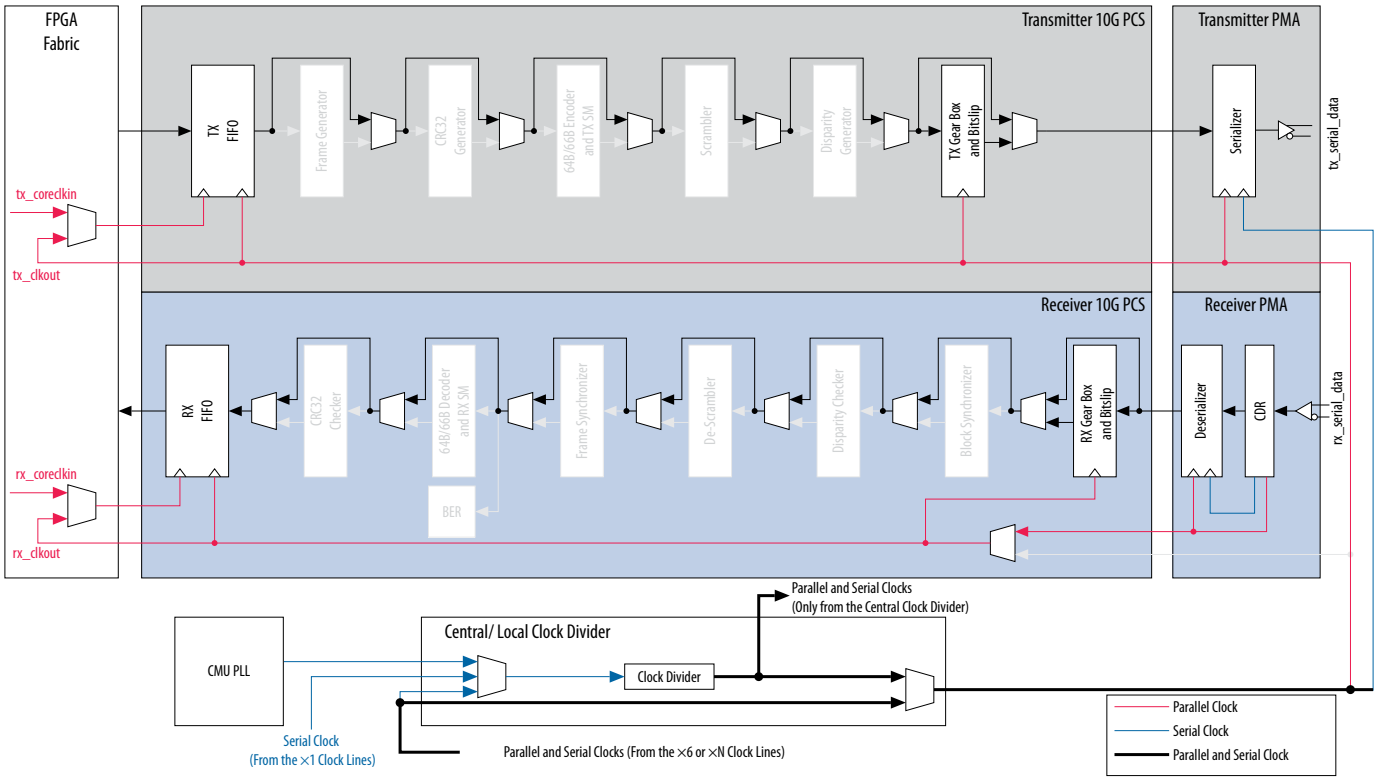


Figure 6-65: Options for 10G PCS Low Latency Configuration

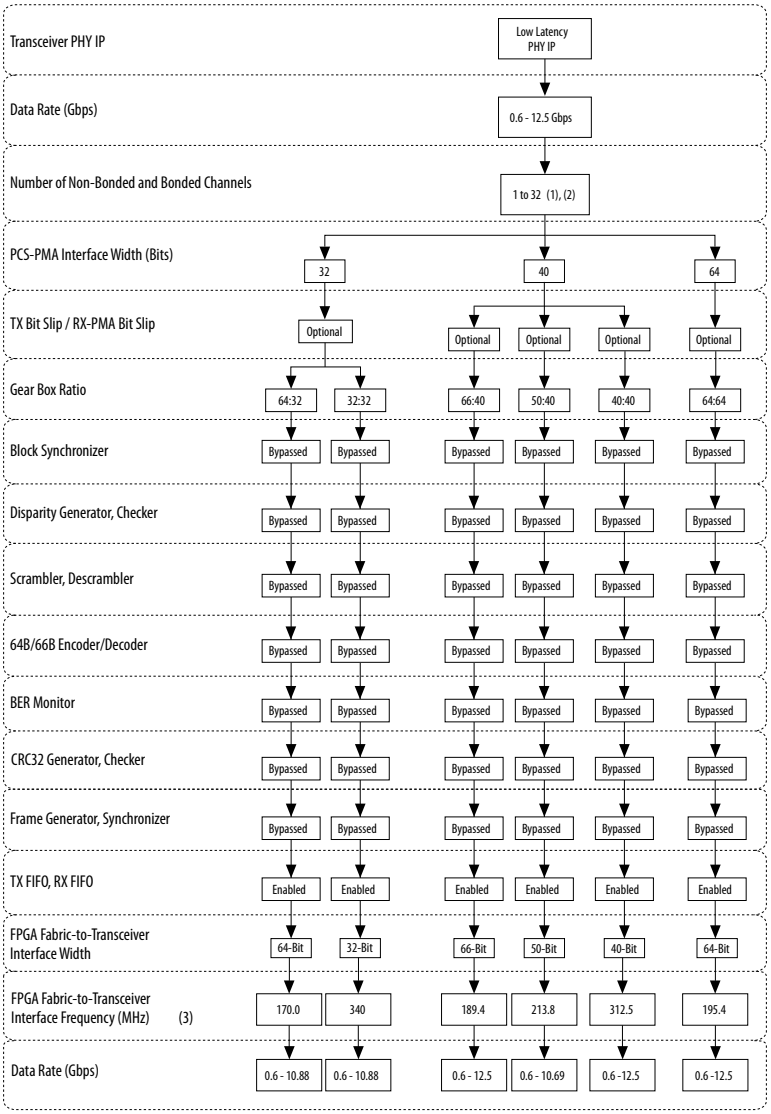
The blocks shown as "Disabled" are not used but incur latency. The blocks shown as "Bypassed" are not used and do not incur any latency. The FPGA fabric-to-transceiver interface maximum frequency is for the fastest speed grade devices.



Notes:
(1) For xN bonding, the number of bonded channels is up to four using CMU PLL and up to six using ATX PLL, provided the data rate is supported by the CMU PLL and ATX PLL.
(2) Bonding more than six channels requires PLL feedback compensation bonding. PLL feedback compensation bonding requires one PLL per transceiver bank and the PLL reference clock frequency must have the same value as the lane data rate divided by the serialization factor.
(3) You must generate an rx_coreclkin with the specified frequency whenever the gear box is enabled.

The Quartus II software supports both non-bonded configuration and bonded configurations up to 32 lanes in the link when the 10G PCS in low latency datapath configuration is enabled. If you create multiple non-bonded channels with the 10G PCS in low latency mode, a common parallel clock (used in the bonded lane or channel configuration) is not generated by the central clock divider block. Each transmitter channel takes the high-speed clock, generated by the channel PLL, and locally divides it to generate the parallel clock.

Related Information

- **For the limits of all speed grades, refer to the "Transceiver Performance Specifications" section in the Arria V Device Datasheet**

- **Refer to the Low Latency PHY IP Core chapter in the Altera Transceiver PHY IP Core User Guide**

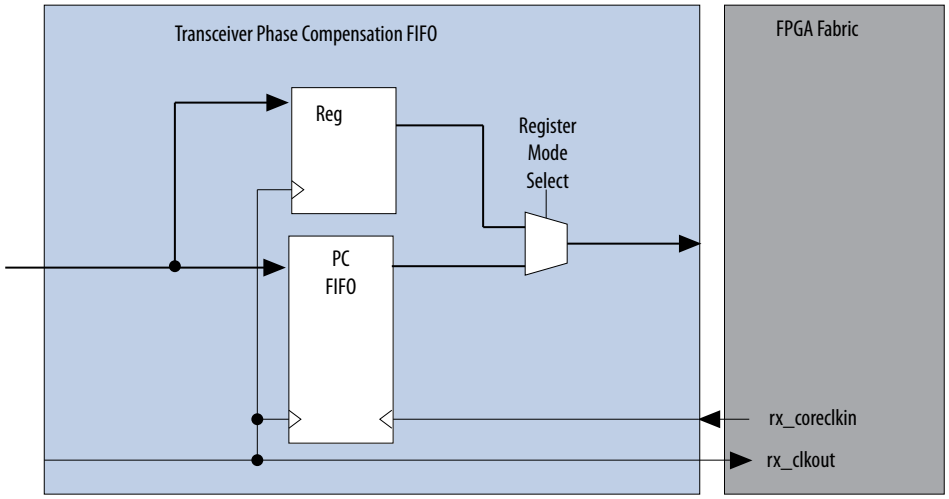
10G PCS Datapath Functionality

Various 10G PCS blocks are available when you implement the 10G PCS in low latency mode.

Transmitter and Receiver FIFO

The FIFOs can be configured in phase compensation or registered mode for the RX path. In phase compensation mode, the FIFO compensates the phase differences in the clock between the read and write side of the FIFO. The clocking scheme for the write side of the transmitter (TX) and receiver (RX) FIFOs depends on whether the gear box is enabled and on its ratio (40:66, 40:50, or 32:64). The clocking scheme is described in **Clocking** on page 1-81.

Figure 6-66: Phase Compensation FIFO in RX Path



Gear Box

The gear box translates the datapath width differences between the PCS and the physical medium attachment (PMA) interfaces. The gear box contains handshake control logic and FIFOs to implement the data-width translation. For the supported gear box ratio, refer to figure "Options for 10G PCS Low Latency Configuration".

TX Bit Slip Feature

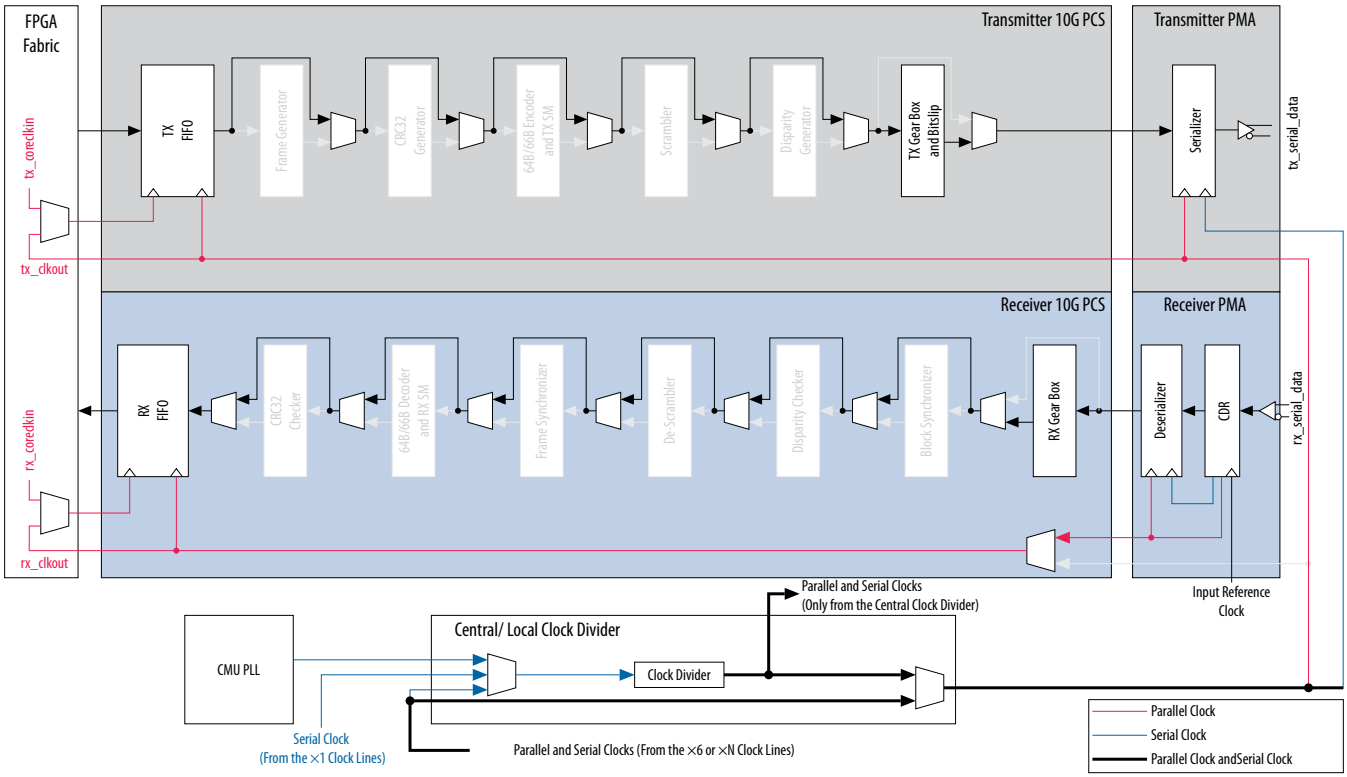
The bit slip feature allows you to slip the transmitter side bits before they are sent to the gear box. The number of bits slipped is equal to the FPGA fabric-to-transceiver interface width minus 1. For example, if the FPGA fabric-to-transceiver interface width is 64 bits, a maximum of 63 bits can be slipped. That is, `bit[63]` from the first word and `bit[62:0]` are concatenated to form a 64 bit word (`bit[62:0]` from the second word, `bit[63]` from the first word LSB). The 7-bit input control signal is available to the FPGA fabric. For a 63-bit shift mentioned above, set the value of the input control to 7'b0011111.

Clocking

The transceiver datapath clocking scheme depends on the gear box ratio.

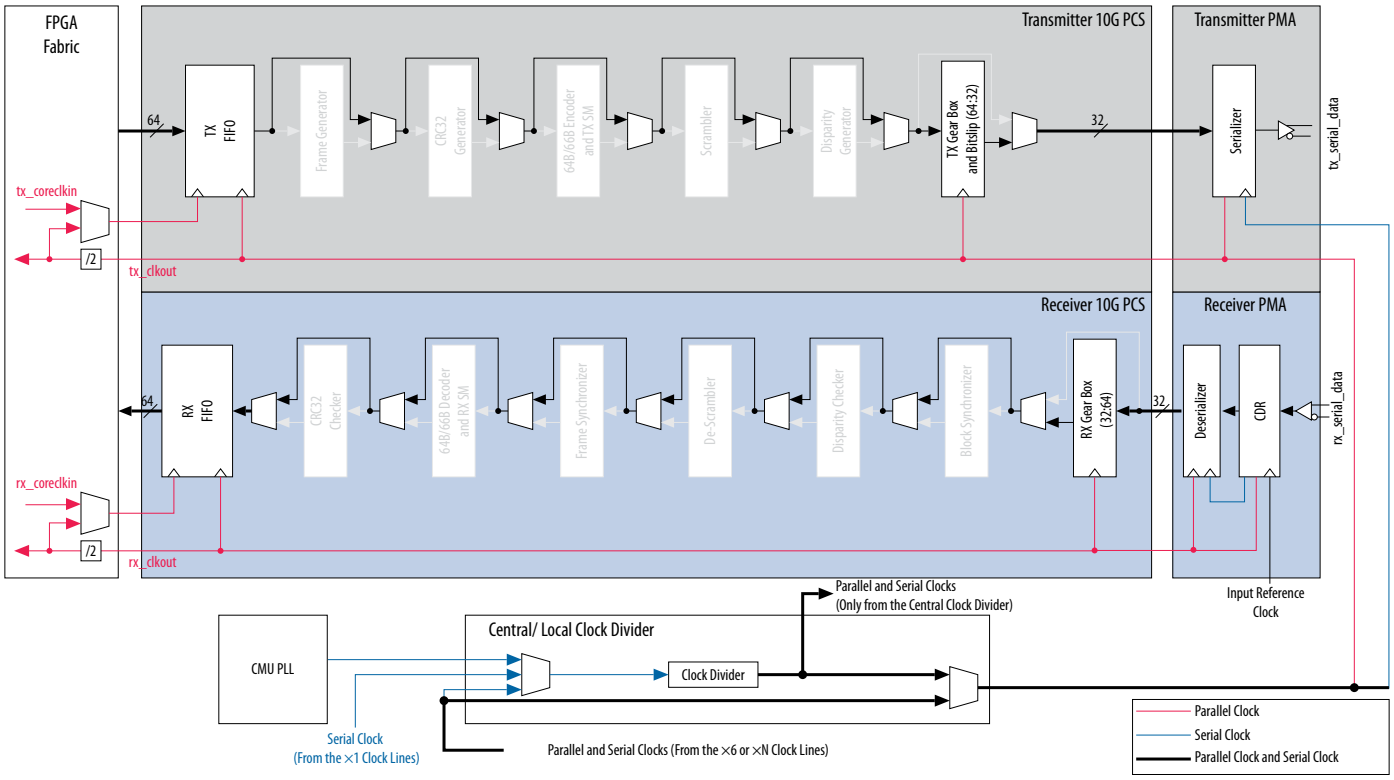
When the gear box ratio is 64:64, 40:40, or 32:32, there is no frequency difference between the read and write side of the TX and RX FIFO clocks because the gear box is the same ratio. The Quartus II software automatically connects the clocks to the read and write side of the TX FIFO and RX FIFO. In this configuration, the data from the TX FIFO is still fed to the gear box before being sent to the serializer. The gear box cannot be bypassed or disabled.

Figure 6-67: 10G PCS Low Latency Datapath with Gear Box in 64:64, 40:40, and 32:32 Ratio



When the gear box ratio is 64:32. The FPGA fabric interface width (64 bits) is exactly twice the internal transceiver datapath width. You can divide the `tx_clkout` and `rx_clkout` in the FPGA fabric by two, and use them to clock the write side of TX FIFO and the read side of RX FIFO, respectively. Select the `tx_coreclkin` and the `rx_coreclkin` ports in the Low Latency PHY IP core and connect the divided clock to these ports.

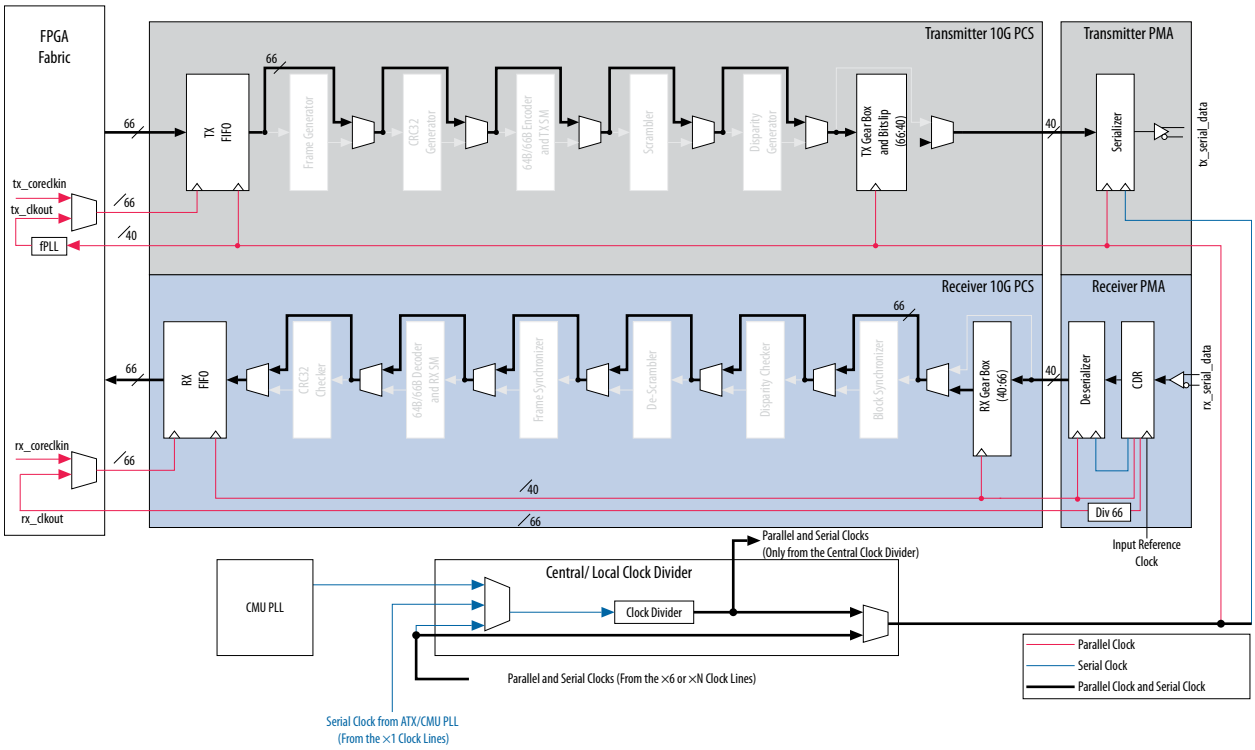
Figure 6-68: 10G PCS Low Latency Datapath with the Gear Box Ratio of 64:32



When the gear box ratio is 66:40, the `rx_clkout` parallel clock provided is a recovered clock coming from the CDR with a divided-by-66 output frequency.

The `tx_clkout` parallel clock is generated from the transmit PLL feeding a fractional PLL that is automatically instantiated from the FPGA core with a divided-by-66 output frequency.

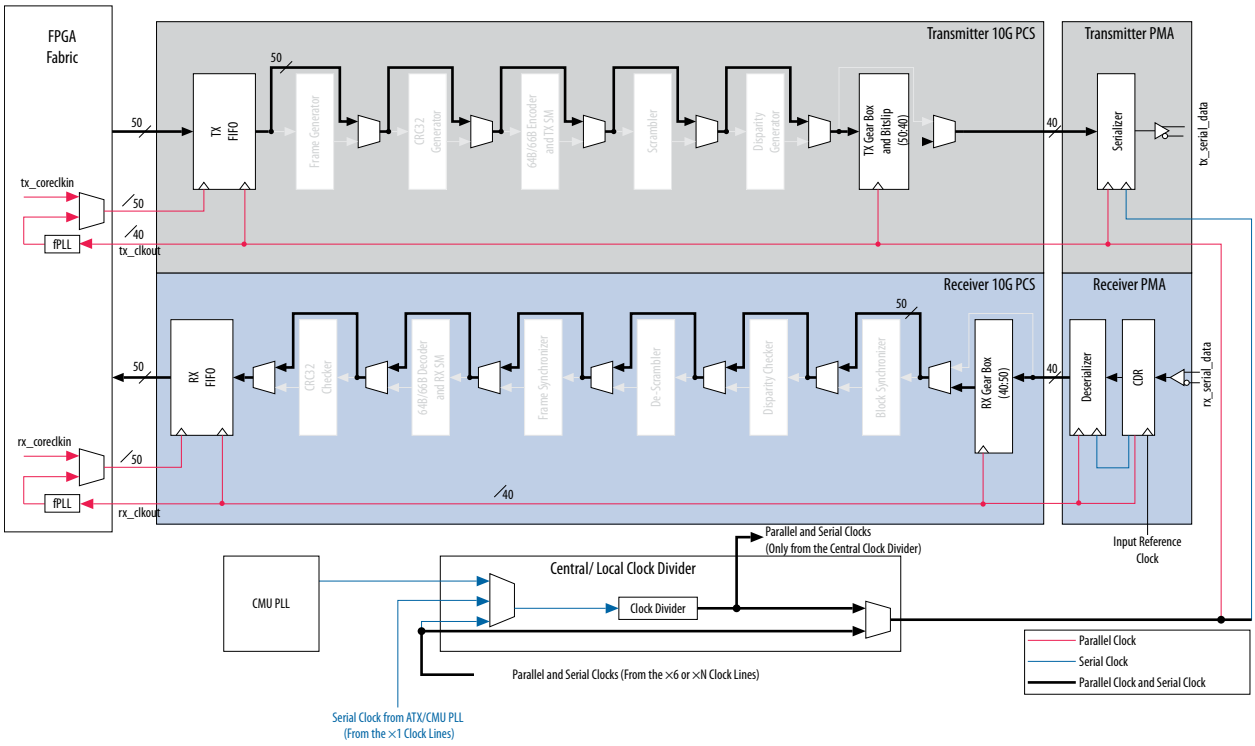
Figure 6-69: 10G PCS Low Latency Datapath with the Gear Box Ratio of 66:40



When the gear box ratio is not an integral multiple of the FPGA fabric interface width (for example, 50:40), you must instantiate a fractional PLL to provide the appropriate clock frequency to the write side of the TX FIFO. Set the division factor in the fractional PLL so that its output frequency is equal to the transmitter or lane data rate divided by 50 for the 50:40 gear box ratio. The clock source that provides the input reference clock to the fractional PLL and the CMU or ATX transmit PLL must be the same because the TX FIFO operates as a phase compensation FIFO, unlike a clock compensation or rate match FIFO. Therefore, the clock requires a zero ppm between the read and write operations.

For the receiver side, enable the `rx_coreclkin` port and connect a second fractional PLL output to the `rx_coreclkin` port. The RX FIFO operates as a phase compensation FIFO. Therefore, the read and write side of the RX FIFO must have a zero ppm difference.

Figure 6-70: 10G PCS Low Latency Datapath with the Gear Box Ratio of 50:40



Note:
(1) The clock source that provides the input reference clock to the fractional PLL (fPLL) and the CMU or ATX PLL (the CMU or ATX PLL generates the high-speed clock for the serializer) must be the same. The transmitter and the receiver FIFOs compensates only for phase differences. Therefore, the same clock source ensures zero ppm between the read and write clocks of the FIFOs.

Using the coreclkin Ports

The `tx_coreclkin` and `rx_coreclkin` ports offer the flexibility to use the `tx_clkout` and `rx_clkout` from one channel to clock the TX and RX FIFOs multiple channels for source synchronous links or if the upstream transmitters are all clocked by the same clock source. The `tx_coreclkin` and `rx_coreclkin` ports require a zero ppm difference between the `tx_clkout` and `rx_clkout` ports, respectively, with a divided-by-50 input frequency.

Related Information

For more information, refer to the "Selecting a Transmitter Datapath Interface Clock" and "Selecting a Receiver Datapath Interface Clock" sections in the Transceiver Clocking in Arria V Devices chapter

Merging Instances

You can merge transmitter and receiver instances with the different 10G PCS datapath configurations in the same 10 Gbps physical channel.

For example, the Quartus II software allows you to create the two following instances and place them in the same physical transceiver channel:

- Transmitter only instance with a 40-bit FPGA fabric interface
- Receiver only instance with a 64-bit FPGA fabric interface

However, you cannot merge a transmitter instance and receiver instance (1 channel instance) using different PCS blocks (10G PCS and standard PCS) within the same physical transceiver channel.

Transceiver Channel Placement Guidelines

Arria V GZ devices allow the placement of up to four or five channels when a CMU PLL is used or up to six channels when an ATX PLL is used with Custom and Low Latency datapath configurations with Standard PCS and 10G PCS (same data rate) within the same transceiver bank.

Related Information

Transceiver Channel Placement Guidelines on page 6-76
You can use CMU PLLs or ATX PLLs in non-bonded and bonded configurations.

Native PHY IP Configuration

The Native PHY IP is a full exposure of the transceiver hardware features with little abstraction of the physical hardware layer.

Access to both the Standard PCS and 10G PCS hardware, as well as PMA Direct modes can be enabled with full user control over the transceiver interfaces, parameters, and ports. Enable the Standard PCS and 10G PCS or PMA Direct mode to design for multi-datarate protocols, speed negotiation, and support multiple PCS datapath natively on the transceiver link.

The Transceiver Reconfiguration Controller is used to dynamically switch between the Standard PCS and 10G PCS datapaths. In addition, the Reconfiguration Controller is required for calibration, remote loopback enablement, PLL reference clock switching, channel PCS and PLL reconfiguration and switching, and to dynamically adjust PMA transmit pre-emphasis, receiver CDR, CTLE, and DFE advance settings.

Dynamic switching to and from PMA Direct mode is not supported.

Not all hardware combinations are legal or supported, so the user must have sufficient prior knowledge of the transceiver hardware, PLLs, and clocking architecture to determine valid PCS hardware setting, parameters, and combinations. All serial transceiver protocols can be supported by the Native PHY IP.

Note: Altera recommends all new serial protocol designs use the Native PHY IP with the exception of XAUI and PCI Express. A default preset is provided for ASI, SDI, SRIO, CPRI, GIGE, Interlaken, SAS, SATA, and other protocol configurations as well as Low Latency configurations for the Standard PCS and 10G PCS similar to the Low Latency PHY IP implementation. Users can also select the default preset for guidance and then modify the configurations for custom applications and have the ability to save the modified preset.

The transmit CMU or ATX Phase-Locked Loop (PLL) selection is embedded in the PHY IP. In addition, the fractional PLL (fPLL) can now be used as a transmit PLL for lane datarates up to 3.125Gbps. User must select the appropriate PLL for balancing datarate and jitter performance trade-off requirements. Unlike the other PHY IPs, the Native PHY IP does not have an Avalon Memory-Mapped (Avalon-MM) interface as the intent is to have direct access to the port interfaces. As a result, there are no embedded registers. In addition, the reset controller is also not embedded in the Native PHY IP. Altera recommends that the Transceiver PHY Reset Controller IP is used to implement the reset sequence and to make PLL sharing and merging effortless.

To implement a Native PHY link, instantiate the **Arria V Transceiver Native PHY IP** in the IP Catalog, under **Transceiver PHY** in the Interfaces menu. Select options to generate valid custom transceiver configurations or select the default preset for by double-clicking in the window menu.

Native PHY Transceiver Datapath Configuration

The following figure shows the transceiver Standard PCS blocks, 10G PCS blocks, and their settings in addition to PMA Direct Mode available in a Native PHY IP configuration.

(42) Nx Multi-Alignment Deskew State Machine must be implemented in the core.

Figure 6-71: Transceiver Blocks in a Native PHY IP Configuration

The Optional PCS blocks that are "Disabled" are not used, but incur latency. The Optional PCS blocks selected as "Bypassed" are not used and do not incur latency.

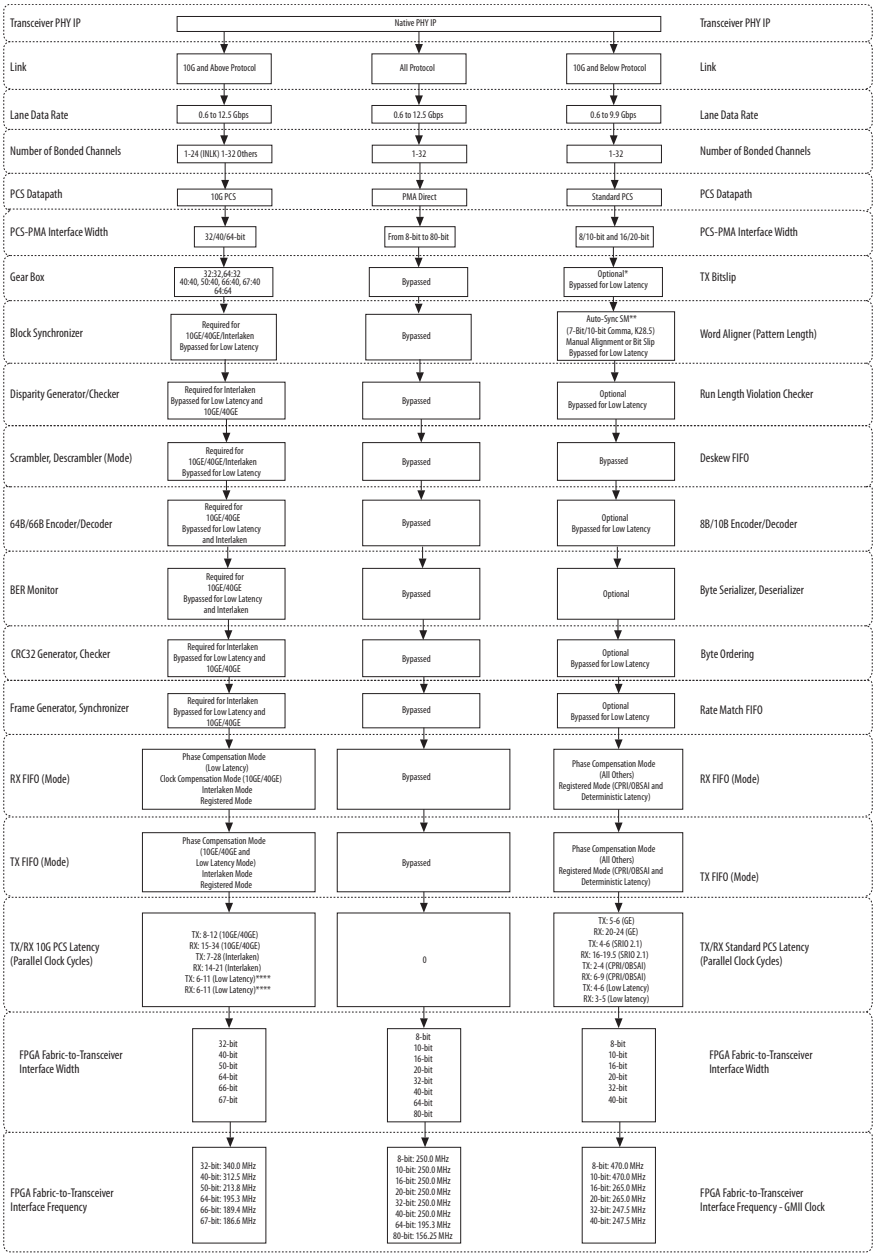

Figure 6-72: Native PHY IP Datapath Configuration

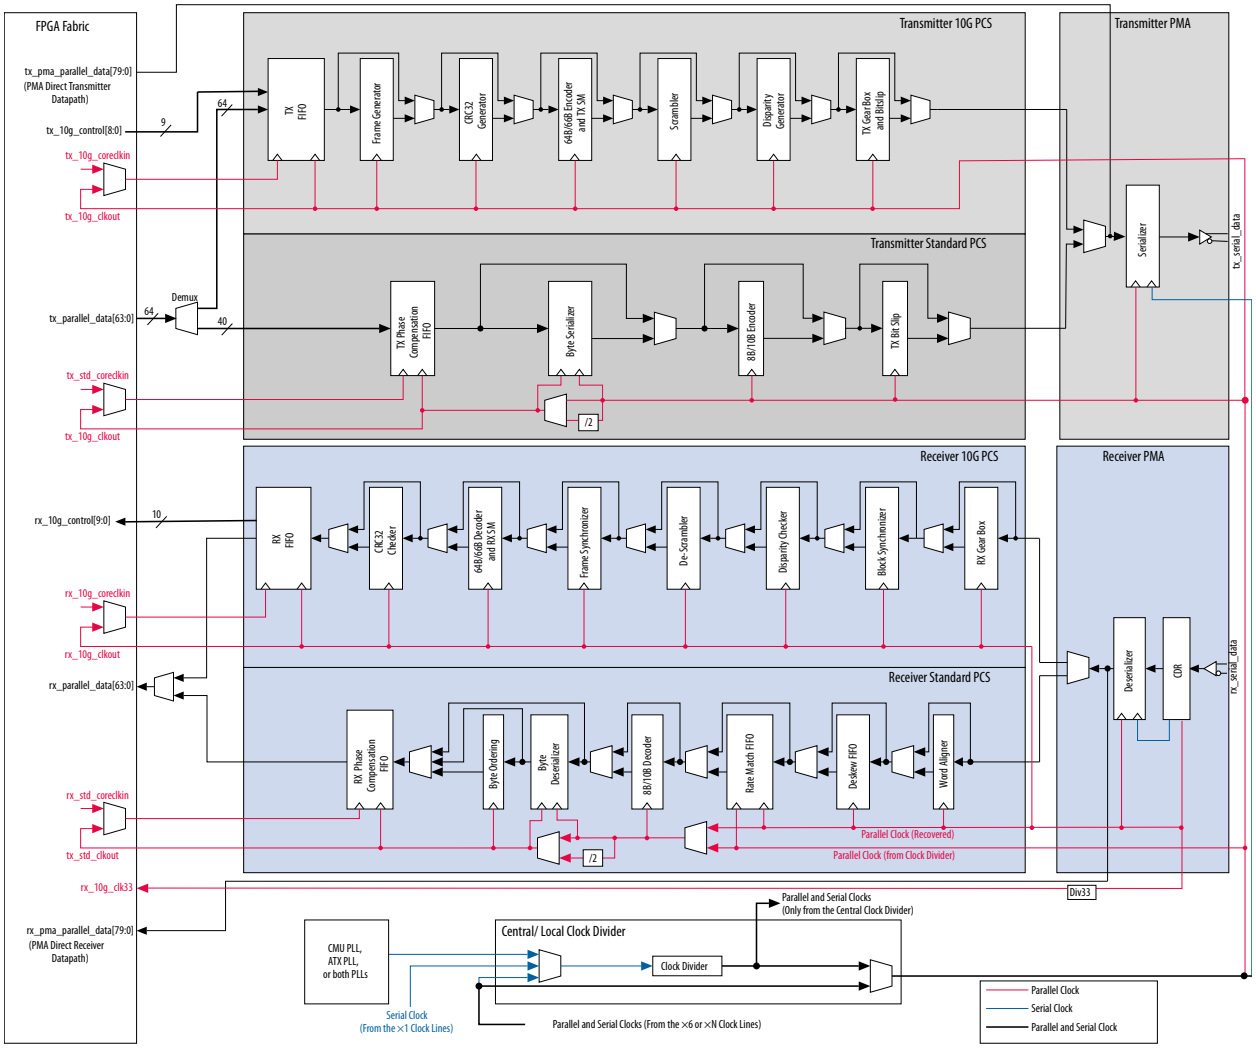
The following figure shows the Standard PCS and 10G PCS blocks, their associated datapaths, and the PMA Direct datapath available for implementation with the Native PHY IP.



Standard PCS Features

The Standard PCS can reach lane datarates up to 9.9 Gbps with the widest PCS-PMA width and FPGA fabric-to-transceiver interface width configuration. The Standard PCS is used when supporting protocols with lane datarates below 10 Gbps such as Gigabit Ethernet, CPRI/OBSAI, SD/HD/3G-SDI, HiGig, Hypertransport, SRIO, JESD204A, SATA and SAS, 1G/2G/4G/8G Fibre Channel, GPON/EPON, SFI-4.2/SFI-5.1, TFI, SPI-4.2/SPI-5.1, STS-12/12c, STS-48/48c, OTU-0.

Standard PCS Receiver and Transmitter Blocks

To implement a Native PHY link with the Standard PCS datapath, instantiate the **Arria V Transceiver Native PHY IP** in the IP Catalog, under **Transceiver PHY** in the Interfaces menu. Select option to enable the Standard PCS by checking the box. A Standard PCS tab appears with the parameters and configuration options for each block.

The following blocks can be enabled or disabled and configured in the Standard PCS.

- Word Aligner
- Deskew FIFO
- Rate Match FIFO
- 8B/10B Encoder/Decoder
- Byte Serializer/De-Serializer
- Byte Ordering
- Receive Phase Compensation FIFO (Can also be configured as registered mode)
- Transmit Phase Compensation FIFO (Can also be configured as registered mode)
- TX Bitslipper

10G PCS Supported Features

The 10G PCS supports protocols with lane datarates that are 10Gbps and above, such as 10/40 Gigabit Ethernet, Interlaken, SPAUI, 10G SDI, 10G Fibre Channel, Infiniband, 10G GPON/EPON, SFI-5.2, STS-192/192c, STS-768/768c, OTU-2/3. The 10G PCS can reach lane datarates up to 12.5 Gbps with the widest FPGA fabric-to-transceiver interface width configuration.

10G PCS Receiver and Transmitter Blocks

To implement a Native PHY link with the 10G PCS datapath, instantiate the **Transceiver Native PHY IP** in the IP Catalog, under **Transceiver PHY** in the Interfaces menu. When you select the 10G PCS option, a 10G PCS tab appears with the parameters and configuration options for each block.

The following blocks below can be enabled and disabled and configured in the 10G PCS.

- Receive and Transmit FIFO
- CRC32 Generator/Checker
- Metaframe Generator/Synchronizer
- 64B/66B Encoder/Decoder
- Scrambler/Descrambler
- Disparity Generator/Checker
- Block Synchronizer
- Multi-Gearbox

The hard PCS blocks natively support 10/40 Gigabit Ethernet and Interlaken. The remaining protocols are supported via 10G PCS Low Latency datapath configuration with the appropriate gearbox ratios.

10/40 Gigabit Ethernet Blocks Supported Configuration:

- Receiver FIFO in Clock Compensation Mode and Transmit FIFO in Phase Compensation Mode
- 64B/66B Encoder/Decoder
- Scrambler/Descrambler
- Block Synchronizer
- 66:40 Gearbox Ratio

10/40 Gigabit Ethernet Blocks with 1588 Supported Configuration:

- Receiver and Transmit FIFO in Registered Mode
- 64B/66B Encoder/Decoder
- Scrambler/Descrambler
- Block Synchronizer
- 66:40 Gearbox Ratio

Interlaken Blocks Supported Configuration:

- Receiver and Transmit FIFO in Interlaken Elastic Buffer (Generic) Mode
- CRC32 Generator/Checker
- Metaframe Generator/Synchronizer
- Scrambler/Descrambler
- Disparity Generator/Checker
- Block Synchronizer
- 67:40 Gearbox Ratio

SFI-5.2 Blocks Supported Configuration:

- Receiver and Transmit FIFO in Phase Compensation Mode
- 64:64, 40:40, 64:32, and 32:32 Gearbox Ratios

10G SDI Blocks Supported Configuration:

- Receiver and Transmit FIFO in Phase Compensation Mode
- 50:40 Gearbox Ratio

Other Protocol Blocks Supported Configuration in Basic Mode:

- Receiver and Transmit FIFO in Phase Compensation Mode
- 64:64, 66:40, 40:40, 64:32, and 32:32 Gearbox Ratios

Related Information

- **Altera Transceiver PHY IP Core User Guide**

Receiver and Transmit Gearbox in Native PHY IP

The Native PHY IP supports many 10G PCS:PMA gearbox ratios.

Users have the freedom to choose the best gearbox ratio that matches their core IP. The 67:40 is mainly used for Interlaken configurations and the 66:40 ratio is mainly used in 10, 40, and 100 Gigabit Ethernet configurations and the 50:40 is used in 10 Gigabit SDI applications. The other ratios can support additional standard communication and transport protocols such as GPON, EPON, SFI-5.2 and OTN.

10G PCS Supported Gearbox Ratios:

- 64:64 PCS:PMA Width
- 67:40 PCS:PMA Width
- 66:40 PCS:PMA Width
- 50:40 PCS:PMA Width
- 40:40 PCS:PMA Width
- 64:32 PCS:PMA Width
- 32:32 PCS:PMA Width

10G Datapath Configurations with Native PHY IP

Table 6-13: 10G PCS Datapath Configurations

The table lists the 10G PCS datapath configuration for 10/40 Gigabit Ethernet, 10/40 Gigabit Ethernet with 1588, Interlaken, 10G SDI, and other 10G protocols.

Transceiver PHY IP	Native PHY IP					
Link	10/40GBASE-R/KR	10/40GBASE-R with 1588	Interlaken	SFI-5.2	10G SDI	Other 10G Protocols (Basic Mode)
Lane Datarate	10.3125Gbps	10.3125Gbps	3.125 - 12.5Gbps	0.6 - 12.5Gbps(43)	10.692Gbps	0.6 - 12.5Gbps (43)
PMA Channel Bonding Option(44) (45)	Non-bonded, xN,feedback compensation	Non-bonded, xN, feedback compensation	Non-bonded	Non-bonded, xN, feedback compensation	Non-bonded, xN, feedback compensation	Non-bonded, xN, feedback compensation
PCS Datapath	10G PCS	10G PCS	10G PCS	10G PCS	10G PCS	10G PCS
PCS-PMA Interface Width (Serialization Factor)	40-bit	40-bit	40-bit	32/40/64-bit	40-bit	32/40/64-bit
Gearbox Ratios	66:40 (46)	66:40 (46)	67:40	32:32, 64:32(46), 40:40, 64:64	50:40 (46)	32:32, 64:32(46), 40:40, 66:40(46), 64:64

(43) Gearbox ratios of 64:32 and 32:32 have a maximum supported datarate of 10.88Gbps.
(44) For xN bonding, the number of bonded channels is up to four using CMU PLL and up to six using ATX PLL, provided the data rate is supported by the CMU PLL and ATX PLL.
(45) Bonding more than six channels requires PLL feedback compensation bonding. PLL feedback compensation bonding requires one PLL per transceiver bank and the PLL reference clock frequency must have the same value as the lane data rate divided by the serialization factor.
(46) May require the use of an internal fractional PLL (fPLL) for selected Gearbox ratio.

Transceiver PHY IP	Native PHY IP					
Link	10/ 40GBASE-R/ KR	10/ 40GBASE-R with 1588	Interlaken	SFI-5.2	10G SDI	Other 10G Protocols (Basic Mode)

Transceiver PHY IP	Native PHY IP					
Link	10/ 40GBASE-R/ KR	10/ 40GBASE-R with 1588	Interlaken	SFI-5.2	10G SDI	Other 10G Protocols (Basic Mode)
TX/RX 10G PCS Latency (Parallel Clock Cycles) (47)	TX: 8-12 RX: 15-34	TX: 1-4 RX: 2-5	TX: 7-28 RX: 14-21	TX: 6-10 (64:32) TX: 7-10 (64:64, 40:40, 32:32) RX: 6-10 (64:32) RX: 7-10 (64:64, 40:40, 32:32)	TX: 7-11 RX: 6-12	TX: 6-10 (64:32) TX: 6-11 (66:40) TX: 7-10 (64:64, 40:40, 32:32) RX: 6-10 (64:32) RX: 6-11 (66:40) RX: 7-10 (64:64, 40:40, 32:32)
FPGA Fabric-to- Transceiver Interface Widths	66-bit	66-bit	67-bit	32-bit 40-bit 64-bit	50-bit	32-bit 40-bit 64-bit 66-bit
FPGA Fabric-to- Transceiver Interface Width Maximum Frequencies	66-bit: 156.25 MHz	66-bit: 156.25 MHz	67-bit: 78.125-312.5 MHz (48)	32-bit (32:32) : 340.0 MHz 40-bit (40:40) : 312.5 MHz 64-bit (64:32) : 170.0 MHz (49) 64-bit (64:64) : 195.4 MHz	50-bit: 213.8 MHz (48)	32-bit (32:32): 340.0 MHz 40-bit (40:40): 312.5 MHz 64-bit (64:32): 170.0 MHz (49) 64-bit (64:64): 195.4 MHz 66-bit (66:40): 189.4 MHz (48)

(47) PCS Latency values are with default recommended FIFO partially full and partially empty values. Disabled if Standard PCS 8B/10 Encoder/Decoder is used.
(48) PCS `tx_clkout` frequency output is lane datarate/40 for 10G-SDI, Interlaken, and Basic Mode.
(49) PCS `tx_clkout` frequency output is lane datarate/32 for SFI-S and Basic Mode.

PMA Direct Supported Features

The PMA Direct is used to support protocols that require extremely low or zero transceiver PCS latency such as QPI. In PMA Direct mode, the transceiver can reach lane data rates up to 12.5Gbps with the widest FPGA fabric-to-transceiver interface width configuration.

There are no PCS blocks in the PMA Direct configuration, so clock phase compensation must be designed in the fabric core. Data and clock signals are interfaced directly to the transceiver PMA. Consequently, you must also compensate for the timing and clock phase differences from the core fabric interface of the FPGA to the transceiver PMA. The PMA interface width has a wide range of selections from 8-bit, 10-bit, 16-bit, 20-bit, 32-bit, 40-bit, 64-bit, and 80-bit. The FPGA fabric interface width is fixed at 80-bit and you must select the correct ports for their PMA interface width configurations.

To implement a Native PHY link with the PMA Direct datapath, instantiate the **Transceiver Native PHY IP** in the IP Catalog, under **Transceiver PHY** in the Interfaces menu. Do not select the options to enable the Standard or 10G PCS. The Standard and 10G PCS tabs do not appear, indicating that the PMA Direct datapath configuration has been selected.

Figure 6-72 shows the transceiver PMA Direct datapath and clocking in the device channels.

Channel and PCS Datapath Dynamic Switching Reconfiguration

The Native PHY IP is the only PHY IP that can support transceiver channel dynamic switching between Standard PCS and 10G PCS. Dynamic switching to and from PMA Direct mode is not supported. The dynamic switching mechanism via streamer-based reconfiguration as well as the associated transceiver PLL, standard PMA, and advance transceiver PMA features reconfiguration is employed with the Reconfiguration Controller IP.

Document Revision History

Table 6-14: Document Revision History

Date	Version	Changes
September 2014	2014.09.30	Changed references to MegaWizard Plug-In Manager to IP Catalog.
March 2014	2014.03.07	Updated "Sample Channel Width Options for Supported Serial Data Rates" table in the CPRI and OBSAI section.

Date	Version	Changes
October 2013	2013.10.18	• Updated "Advanced Channel Placement Guidelines for PIPE Configurations" section. • Updated "Transceiver Clocking for PCIe Gen3" section. • Updated "Protocols and Transceiver PHY IP Support" section.
May 2013	2013.05.06	• Added link to the known document issues in the Knowledge Base. • Added second figure to the "10GBASE-R and 10GBASE-KR" section. • Added the "10GBASE-KR Forward Error Correction" section. • Updated the "Transceiver Channel Placement Guidelines for Gen1, Gen2, and Gen3 PIPE Configurations" section. • Added the "Advance Channel Placement Guidelines for PIPE Configurations" section.
November 2012	2012.11.19	Initial release.

Transceiver Loopback Support in Arria V Devices

7

2014.09.30

AV53006 Subscribe Send Feedback

The Arria V loopback options allow you to verify how different functional blocks work in the transceiver.

Related Information

Arria V Device Handbook: Known Issues
Lists the planned updates to the Arria V Handbook chapters.

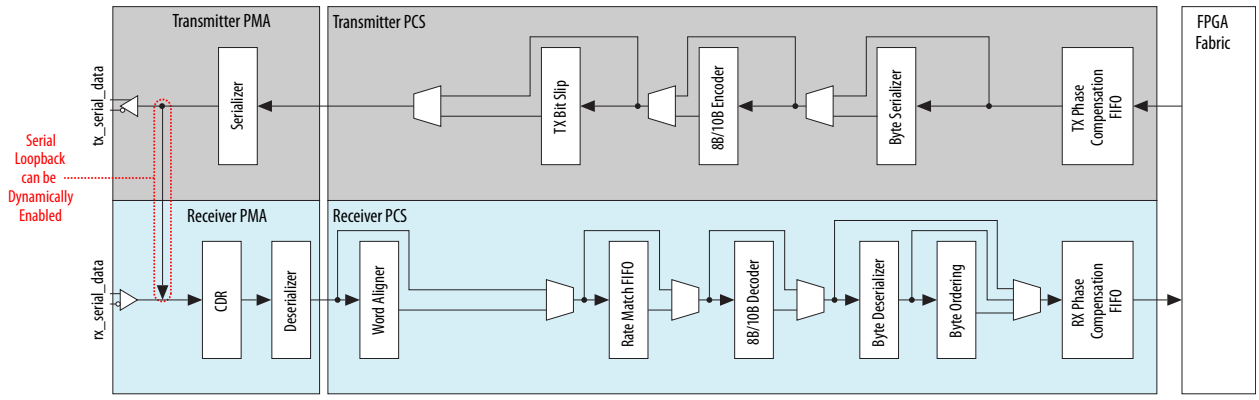
Serial Loopback

Serial loopback is a debugging aid to ensure that the enabled PCS and PMA blocks in the transmitter and receiver channels function correctly.

Serial loopback is available for all transceiver configurations except the PIPE mode. You can use serial loopback as a debugging aid to ensure that the enabled physical coding sublayer (PCS) and physical media attachment (PMA) blocks in the transmitter and receiver channels are functioning correctly. Furthermore, you can dynamically enable serial loopback on a channel-by-channel basis.

The data from the FPGA fabric passes through the transmitter channel and is looped back to the receiver channel, bypassing the receiver buffer. The received data is available to the FPGA logic for verification.

Figure 7-1: Serial Loopback Datapath



You can enable serial loopback using the PHY IP Parameter Editor or the reconfiguration controller, depending on which PHY IP mode you select. When you enable serial loopback, the transmitter channel sends data to both the `tx_serial_data` output port and to the receiver channel. The differential output voltage on the `tx_serial_data` port is based on the selected differential output voltage (V_{OD}) settings.

Note: For more information about the PHY IP core registers, refer to the Altera Transceiver PHY IP User Guide.

The looped-back data is forwarded to the receiver clock data recovery (CDR). You must provide an alignment pattern for the word aligner to enable the receiver channel to retrieve the byte boundary.

If the device is not in the serial loopback configuration and is receiving data from a remote device, the recovered clock from the receiver CDR is locked to the data from the remote source.

If the device is placed in the serial loopback configuration, the data source to the receiver changes from the remote device to the local transmitter channel—prompting the receiver CDR to start tracking the phase of the new data source. During this time, the recovered clock from the receiver CDR may be unstable. Because the receiver PCS is running off of this recovered clock, you must place the receiver PCS under reset by asserting the `rx_digitalreset` signal during this period.

Note: When moving into or out of serial loopback, you must assert the `rx_digitalreset` signal for a minimum of two parallel clock cycles.

Serial Loopback for Arria V GZ Devices

For Arria V GZ devices, you enable serial loopback by accessing the register space within the reconfiguration controller through the Avalon-MM interface.

Related Information

Altera Transceiver PHY IP Core User Guide

Forward Parallel Loopback

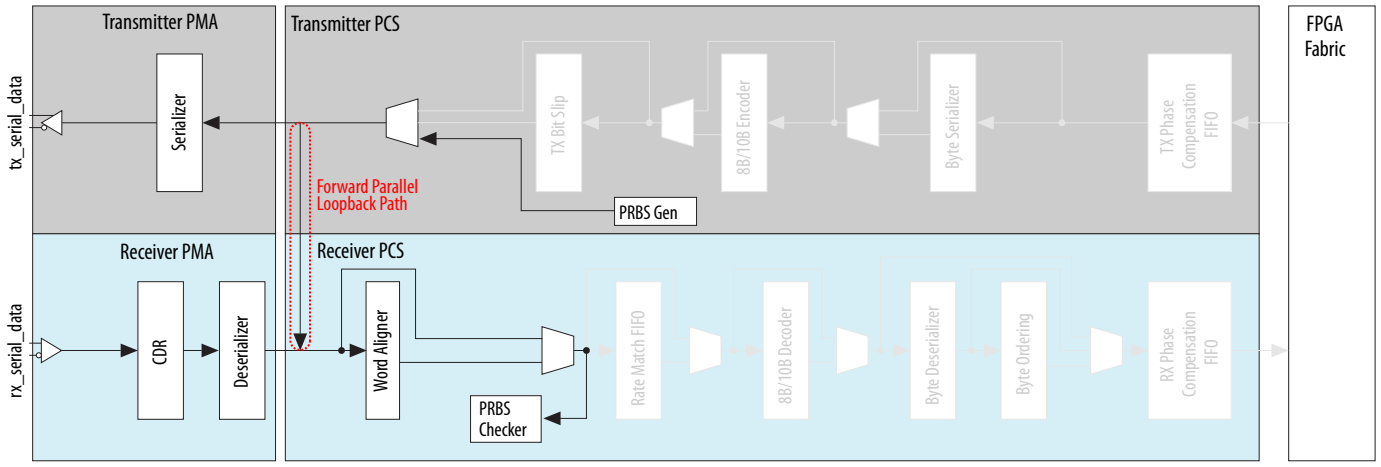
Forward parallel loopback is a debugging aid to ensure the enabled PCS blocks in the transmitter and receiver channel function correctly.

Forward parallel loopback is only available in transceiver Native PHY. You enable forward parallel loopback by enabling the PRBS test mode, through the dynamic reconfiguration controller. You must perform a `rx_digitalreset` after the dynamic reconfiguration operation has completed.

Parallel data travels across the forward parallel loopback path, passing through the RX word aligner, and finally verified inside the RX PCS PRBS verifier block. Check the operations status from the FPGA fabric.

Figure 7-2: Parallel Loopback Datapath

The following figure shows the parallel PRBS data generated by the TX PCS PRBS generator block.



Note: Usage details for the feature are described in the Altera Transceiver PHY IP Core User Guide.

Related Information

Altera Transceiver PHY IP Core User Guide

PIPE Reverse Parallel Loopback

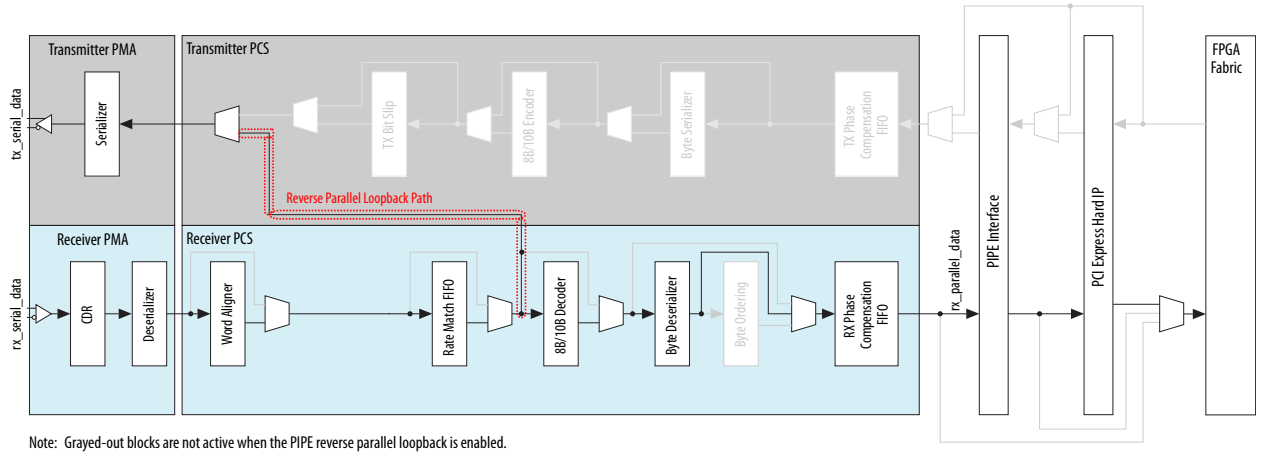
For debugging, the PIPE Reverse Parallel Loopback option uses parallel data through the rate match FIFO, transmitter serializer, and the `tx_serial_data` port path.

PIPE reverse parallel loopback is only available in the PCIe® configuration for Gen1 and Gen2 data rates. The following figure shows the received serial data passing through the receiver CDR, deserializer, word aligner, and rate match FIFO buffer. The parallel data from the rate match FIFO is then looped back to the transmitter serializer and transmitted out through the `tx_serial_data` port. The received data is also available to the FPGA fabric through the `rx_parallel_data` signal.

PIPE reverse parallel loopback is compliant with the PCIe 2.0 specification. To enable this loopback configuration, assert the `pipe_txdetectrx_loopback` signal.

Note: PIPE reverse parallel loopback is the only loopback option supported in the PCIe configuration.

Figure 7-3: PIPE Reverse Parallel Loopback Configuration Datapath



Note: Grayed-out blocks are not active when the PIPE reverse parallel loopback is enabled.

PIPE Reverse Parallel Loopback for Arria V GZ Devices

To enable the loopback configuration for Arria V GZ devices, assert the `tx_detectrx_loopback` signal.

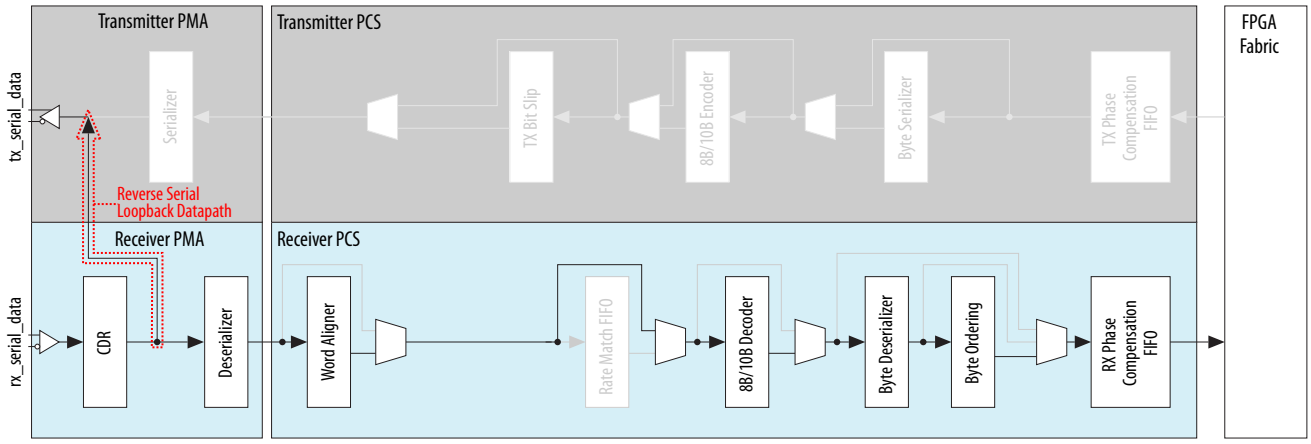
Reverse Serial Loopback

The Reverse Serial Loopback option debugs with data through the `rx_serial_data` port, receiver CDR, and `tx_serial_data` port path.

You can enable reverse serial loopback through the reconfiguration controller. In reverse serial loopback, the data is received through the `rx_serial_data` port, re-timed through the receiver CDR, and sent to the `tx_serial_data` port. The received data is also available to the FPGA logic. No dynamic pin control is available to select or deselect reverse serial loopback.

The transmitter buffer is the only active block in the transmitter channel. You can change the V_{OD} and the pre-emphasis first post tap values on the transmitter buffer through the dynamic reconfiguration controller. Reverse serial loopback is often implemented when using a bit error rate tester (BERT) on the upstream transmitter.

Figure 7-4: Reverse Serial Loopback Datapath



Note: Grayed-out blocks are not active when the reverse serial loopback is enabled.

Reverse Serial Loopback for Arria V GZ Devices

Enable reverse serial loopback by accessing the register space within the reconfiguration controller through the Avalon-MM interface.

Note: For the register definitions needed to enable this functionality, refer to the Altera Transceiver PHY IP Core User Guide.

In reverse serial loopback, the data is received through the `rx_serial_data` port, re-timed through the receiver CDR, and sent out to the `tx_serial_data` port. The received data is also available to the FPGA fabric through the `rx_parallel_data` signal. No dynamic pin control is available to select or deselect reverse serial loopback.

You set the reverse serial loopback with the PMA analog registers in the reconfiguration controller.

The only transmitter channel resource used when implementing reverse serial loopback is the transmitter buffer. You can define the V_{OD} and first post tap values on the transmitter buffer using assignment statements in the project .qsf or in the Quartus II Assignment Editor. You can also change these values dynamically with the reconfiguration controller.

Note: For more information about how to dynamically change these analog settings, refer to the Altera Transceiver PHY IP Core User Guide.

Reverse serial loopback is often implemented when using an external bit error rate tester (BERT) on the upstream transmitter.

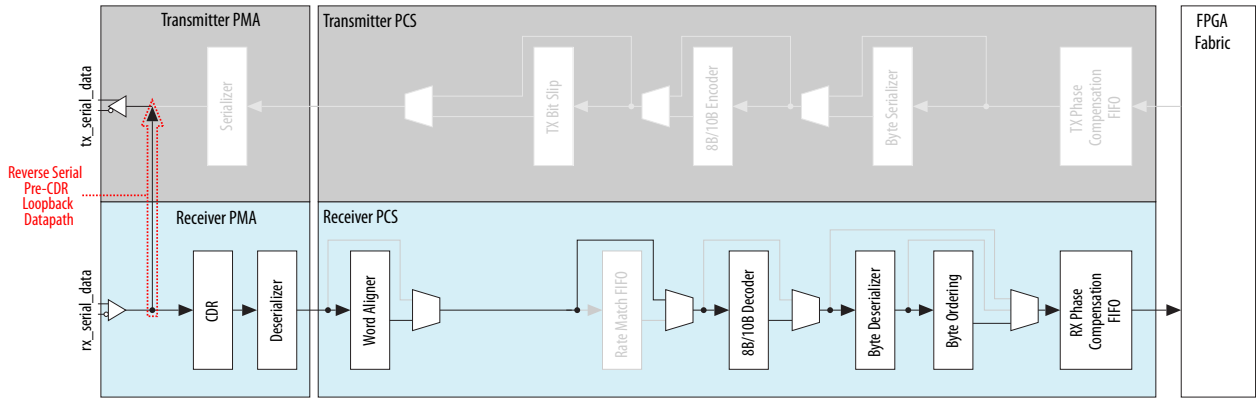
Related Information

Altera Transceiver PHY IP Core User Guide

Reverse Serial Pre-CDR Loopback

The reverse serial pre-CDR loopback option debugs with a data path through the `rx_serial_data` port to the `tx_serial_data` port, and before the receiver CDR.

Figure 7-5: Reverse Serial Pre-CDR Loopback Datapath



Note: Grayed-out blocks are not active when the reverse serial pre-CDR loopback is enabled.

You can enable reverse serial pre-CDR loopback through the reconfiguration controller. In reverse serial pre-CDR loopback, the data received through the `rx_serial_data` port is looped back to the `tx_serial_data` port before the receiver CDR. The received data is also available to the FPGA logic.

The transmitter buffer is the only active block in the transmitter channel. You can change the VOD on the transmitter buffer through the dynamic reconfiguration controller. The pre-emphasis settings for the transmitter buffer cannot be changed in this configuration.

Reverse Serial Pre-CDR Loopback for Arria V GZ Devices

Enable the reverse serial pre-CDR loopback by accessing the register space within the reconfiguration controller through the Avalon-MM interface.

Note: For the register definitions needed to enable this functionality, refer to the Altera Transceiver PHY IP Core User Guide.

In reverse serial pre-CDR loopback, the data received through the `rx_serial_data` port is looped back to the `tx_serial_data` port before the receiver CDR. The received data is also available to the FPGA fabric through the `rx_parallel_data` signal. No dynamic pin control is available to select or deselect reverse serial pre-CDR loopback.

Set the reverse serial pre-CDR loopback with the PMA analog registers in the reconfiguration controller.

The only transmitter channel resource used when implementing reverse serial pre-CDR loopback is the transmitter buffer. You can change the V_{OD} on the transmitter buffer in the available Parameter Editor of the available PHY IP or using the reconfiguration controller. The receiver data characteristics that are looped back in reverse serial pre-CDR loopback are preserved by the transmitter buffer. The pre-emphasis settings for the transmitter buffer cannot be changed in this configuration.

Document Revision History

Table 7-1: Document Revision History

Date	Version	Changes
September 2014	2014.09.30	• Changed Reverse Serial Pre-CDR Loopback section to indicate that VOD transmitter buffer settings can be modified through the Parameter Editor and the reconfiguration controller IP. • Changed MegaWizard Plug-in Manager reference to Parameter Editor.
May 2013	2013.05.06	• Added link to the known document issues in the Knowledge Base. • Updated the Serial Loopback topic. • Added the Forward Parallel Loopback topic. • Updated the Reverse Serial Loopback topic. • Updated the Reverse Serial Pre-CDR Loopback topic.
November 2012	2012.11.19	• Reorganized content and updated template. • Minor updates for the Quartus II software version 12.1.
June 2012	1.2	Minor updates for the Quartus II software version 12.0.
November 2011	1.1	Added the following two loopback options: • "Reverse Serial Loopback" • "Reverse Serial Pre-CDR Loopback"
August 2011	1.0	Initial release.

Dynamic Reconfiguration in Arria V Devices

8

2014.09.30

AV53007 Subscribe Send Feedback

The transceiver reconfiguration controller offers several different dynamic reconfiguration modes. You can choose the appropriate reconfiguration mode that best suits your application needs. All the dynamic reconfiguration modes are implemented through the transceiver Reconfiguration Controller PHY IP.

Related Information

Arria V Device Handbook: Known Issue
Lists the planned updates to the *Arria V Device Handbook* chapters.

Dynamic Reconfiguration Features

The following table lists the available dynamic reconfiguration features.

Table 8-1: Reconfiguration Features

Reconfiguration Feature	Description	Affected Blocks
Offset Cancellation	Counter offset variations due to process operation for the analog circuit. This feature is mandatory if you use receivers.	CDR For Arria V GZ devices, offset cancellation is also available for the RX buffer.
DCD Calibration	Compensates for the duty cycle distortion caused by clock network skew.	TX buffer and clock network skew Arria V GZ devices do not support DCD calibration.
Analog Controls Reconfiguration	Fine-tune signal integrity by adjusting the transmitter (TX) and receiver (RX) analog settings while bringing up a link.	Analog circuit of TX and RX buffer
Loopback Modes	Enable or disable Pre- and Post-CDR Reverse Serial Loopback dynamically.	PMA

Reconfiguration Feature	Description	Affected Blocks
Data Rate Change	Increase or decrease the data rate (/1, /2, /4, /8) for autonegotiation purposes such as CPRI and SATA/SAS applications	TX Local clock dividers
	Reconfigure the TX PLL settings for protocols with multi-data rate support such as CPRI	TX PLL
	Switch between multiple TX PLLs for multi-data rate support	• TX PLL • Fractional PLL (Reconfigure the fPLL data rate with the ALTERA_PLL_RECONFIG megafunction.)
	Channel reconfiguration—Reconfigure the RX CDR from one data rate to another data rate	CDR
	FPGA fabric - transceiver channel data width reconfiguration	FPGA fabric - transceiver channel interface.
On-Chip Signal Quality Monitoring Supported by Arria V GZ devices	EyeQ is a debug and diagnostic tool that analyzes the incoming data, including the receiver's gain, noise level, and jitter after the receive buffer.	CDR
Continuous Time Linear Equalization Supported by Arria V GZ devices	Compensates for backplane losses and dispersion which degrade signal quality. You can implement it adaptively once or continuously.	RX PMA
Decision Feedback Equalization Supported by Arria V GZ devices	Helps compensate for backplane attenuation because of insufficient bandwidth. You can implement it once or continuously.	RX PMA

Related Information

  For information about reconfiguration of the fPLL data rate.

Offset Cancellation

The CDR in all Arria V devices requires offset cancellation. Offset cancellation is available for the RX buffer in Arria V GZ devices only.

Every transceiver channel has offset cancellation circuitry to compensate for the offset variations that are caused by process operations. The offset cancellation circuitry is controlled by the offset cancellation control logic IP within the Transceiver Reconfiguration Controller. Resetting the Transceiver Reconfiguration Controller during user mode does not trigger the offset cancellation process.

When offset cancellation calibration is complete, the `reconfig_busy` status signal is deasserted to indicate the completion of the process.

The clock (`mgmt_clk_clk`) used by the Transceiver Reconfiguration Controller is also used for transceiver calibration. For Arria V GT, GX, ST, and SX devices, `mgmt_clk_clk` must be within the range of 75-125 MHz. For Arria V GZ devices, `mgmt_clk_clk` must be within the range of 100-125 MHz. If the clock (`mgmt_clk_clk`) is not free-running, hold the reconfiguration controller reset (`mgmt_rst_reset`) until the clock is stable.

The clock (`mgmt_clk_clk`) used by the Transceiver Reconfiguration Controller is also used for transceiver calibration and must be 75-125 MHz if the Hard IP for PCIe Express IP core is not enabled. When the Hard IP for PCIe Express is enabled, the frequency range is 75-100 MHz. If the clock (`mgmt_clk_clk`) is not free-running, hold the reconfiguration controller reset (`mgmt_rst_reset`) until the clock is stable.

Transmitter Duty Cycle Distortion Calibration

The duty cycle calibration function tunes the transmitter to minimize duty cycle distortion.

The transmitter clocks generated by the CMU that travel across the clock network may introduce duty cycle distortions (DCD). Reduce DCD with the DCD calibration IP that is integrated in the transceiver reconfiguration controller.

For improved TX jitter performance, enabled the DCD calibration IP in Arria V GX and GT devices if either of the following conditions are met:

- Data rate is ≥ 4915.2 Mbps
- Clock network switching (TX PLL switching) and the data rate is ≥ 4915.2 Mbps

The following DCD calibration modes are supported:

- DCD calibration at power-up mode
- Manual DCD calibration during user mode

DCD calibration is performed automatically after device configuration and before entering user mode if the transceiver channels connected have the **Calibrate duty cycle during power up** option enabled. You can optionally trigger DCD calibration manually during user mode if:

- You reconfigure the transceiver from lower data rates to higher data rates (≥ 4.9152 Gbps)
- You perform clock network switching (TX PLL switching) and switch to data rates of ≥ 4915.2 Mbps

You do not have to enable DCD calibration if the transceivers are operating below 4.9152 Gbps.

Note: If you want to enable the DCD calibration IP for transceiver channels on the left and right sides of the device, use at least one Transceiver Reconfiguration Controller per side of the device. This applies to both power-up and manual DCD modes.

When DCD calibration and offset cancellation are enabled, the `reconfig_busy` status signal from the reconfiguration controller is deasserted to indicate the completion of both processes. If DCD calibration is not enabled, the deassertion of `reconfig_busy` signal indicates the completion of the offset cancellation process.

Note: Arria V GZ devices do not require DCD calibration.

- **Altera Transceiver PHY IP Core User Guide**

PMA Analog Controls Reconfiguration

You can dynamically reconfigure the analog controls setting after offset cancellation is complete and the reset sequence is performed. You can continue with the subsequent reconfigurations of the analog controls when the `reconfig_busy` status signal is low. A high on the `reconfig_busy` signal indicates that the reconfiguration operation is in progress.

You can reconfigure the following transceiver analog controls:

- Transmitter pre-emphasis
- Differential output voltage (V_{OD})
- Receiver equalizer control
- Direct-current (DC) gain settings

To reconfigure the analog control settings, perform read and write operations to the PMA analog settings reconfiguration control IP within the reconfiguration controller.

Related Information

Altera Transceiver PHY IP Core User Guide
For information about the read and write operations with the reconfiguration controller

Dynamic Reconfiguration of Loopback Modes

You can enable the pre- and post-CDR reverse serial loopback modes by writing the appropriate bits of the Transceiver Reconfiguration Controller.

The following loopback paths are available:

- **Post-CDR reverse serial loopback path**— The RX captures the input data and feeds it into the CDR. The recovered data from the CDR output feeds into the TX driver and sends to the TX pins through the TX driver. For this path, the RX and CDR can be tested. For this path, the TX driver can be programmed to use either the main tap only or the main tap and the pre-emphasis first post-tap. Enabling or disabling the post-CDR reverse serial loopback modes is done through the PMA Analog Reconfiguration IP in the Transceiver Reconfiguration PHY IP.
- **Pre-CDR reverse serial loopback path**— The RX captures the input data and feeds it back to the TX driver through a buffer. With this path, you can perform a quick check for the quality of the RX and TX buffers. Enabling or disabling the pre-CDR reverse serial loopback mode.

Note: Serial loopback can be implemented with the transceiver PHY IP directly using the Avalon interface or a control port.

Related Information

Transceiver Reconfiguration Controller chapter of the Altera Transceiver PHY IP Core User Guide

Transceiver PLL Reconfiguration

You can use the PLL reconfiguration registers to switch the reference clock input to the TX PLL or the clock data recovery (CDR) circuitry.

For example, you can switch the reference clock from 100 MHz to 125 MHz. You can also change the data rate from 2.5 Gbps to 5 Gbps by reconfiguring the transmitter PLL connected to the transceiver channel.

Note: Reference clock switching is only supported on the dedicated REFCLK pin.

The Transceiver Reconfiguration PHY IP provides an Avalon ® -MM user interface to perform PLL reconfiguration.

Related Information

"PLL Reconfiguration" section in the Transceiver Reconfiguration Controller chapter of the Altera Transceiver PHY IP Core User Guide
For information about performing PLL reconfiguration.

Transceiver Channel Reconfiguration

You can use channel reconfiguration to dynamically reconfigure the channel in a transceiver PHY IP core. Among the settings that you can change dynamically are the data rate and interface width.

You can reconfigure the channels in the following ways:

- Reconfigure the CDR of the receiver channel.
- Enable and disable all static PCS sub-blocks.
- Select an alternate PLL within the transceiver block to supply a different clock to the transceiver clock generation block.
- Reconfigure the TX local clock divider with a 1, 2, 4, or 8 division factor.

Every transmitter channel has a clock divider. When you reconfigure these clock dividers, ensure that the functional mode of the transceiver channel supports the reconfigured data rate. For example, you can change the data rate from 6.25 Gbps to 3.125 Gbps by reconfiguring the clock divider.

Transceiver Interface Reconfiguration

You can reconfigure the transceiver interfaces by reconfiguring the FPGA fabric transceiver channel data width that includes PCS-PLD and PMA-PCS interfaces.

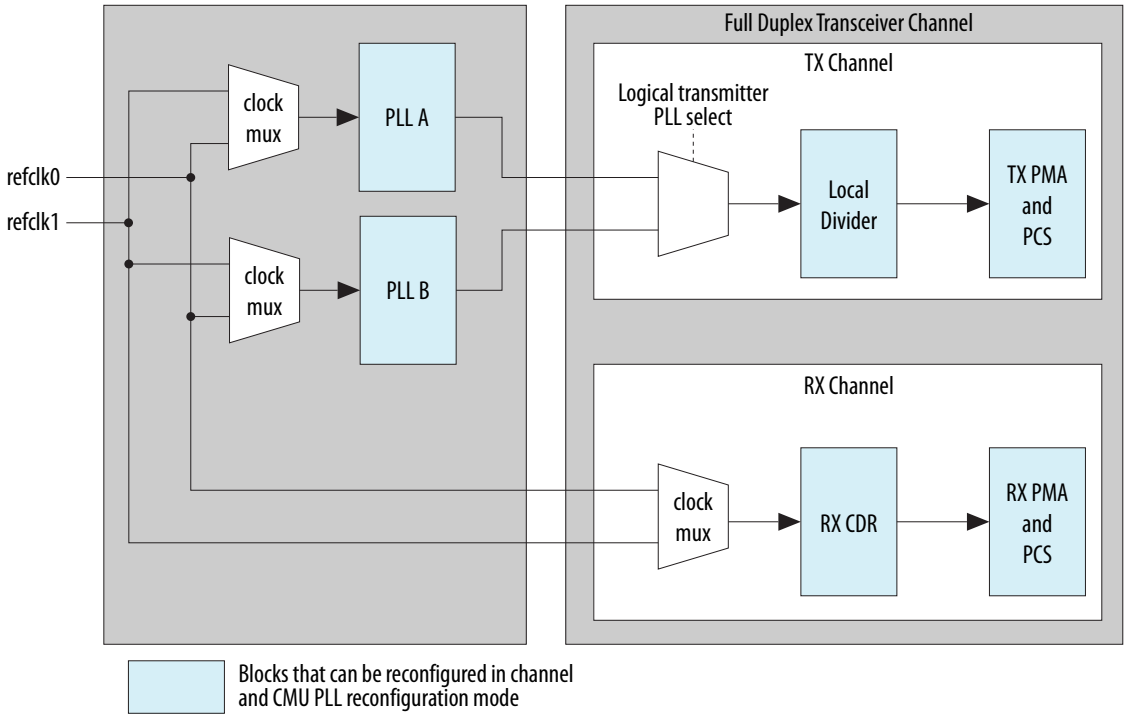
For example, you can reconfigure the custom PHY IP to enable or disable the 8B/10B encoder/decoder. There is no limit to the number of functional modes you can reconfigure the transceiver channel to if the various clocks involved support the transition. When you switch the custom PHY IP from one function mode to a different function mode, you may need to reconfigure the FPGA fabric-transceiver channel data width, enable or disable PCS sub-blocks, or both, to comply with the protocol requirements.

Channel reconfiguration only affects the channel involved in the reconfiguration (the transceiver channel specified by the unique logical channel address), without affecting the remaining transceiver channels controlled by the same Transceiver Reconfiguration Controller. PLL reconfiguration affects all channels that are currently using that PLL for transmission.

Channel reconfiguration from either a transmitter-only configuration to a receiver-only configuration or vice versa is not allowed.

Figure 8-1: Transceiver Channel and PLL Reconfiguration in a Transceiver Block

The following figure shows the functional blocks you dynamically reconfigure using transceiver channel and PLL reconfiguration mode.



Related Information

"Channel and PLL Reconfiguration" section in the Transceiver Reconfiguration Controller chapter of the Altera Transceiver PHY IP Core User Guide
For information about transceiver channel and PLL reconfiguration.

Reduced .mif Reconfiguration

Reduce reconfiguration time by reconfiguring only the affected blocks in the transceiver channels.

This reconfiguration mode affects only the modified settings of the channel to reduce reconfiguration time significantly. For example, in SATA/SAS applications, auto-rate negotiation must be completed within a short period of time to meet the protocol specification. The reduced **.mif** method helps to reconfigure the channel to meet these specifications. You can generate the reduced **.mif** files manually or by using the **xcvr_diffmifgen.exe** utility.

Related Information

Altera Transceiver PHY IP Core User Guide
For information about reduced **.mif** creation.

On-Chip Signal Quality Monitoring (EyeQ)

The bit error rate (BER) eye contour can be used to measure the quality of the received data. EyeQ is a debug and diagnostic tool that analyzes the received data recovery path, including the receiver's gain, noise level, and recovery clock jitter. EyeQ can also measure vertical eye height, effectively allowing a BER eye contour to be plotted.

EyeQ is supported by Arria V GZ devices and not Arria V GX and GT devices. .

EyeQ uses a phase interpolator (PI) and sampler (SMP) to estimate the horizontal eye opening. Controlled by a logic generator, the PI generates a sampling clock and the SMP samples the data from the receiver output. The SMP outputs parallel data that is monitored for CRC or BER errors. When the PI output clock phase is shifted by small increments, the data error rate goes from high to low to high if the receiver is good. The number of steps of valid data is defined as the width of the eye. If none of the steps yield valid data, the width of the eye is equal to 0, which means the eye is closed.

The Transceiver Reconfiguration Controller provides an Avalon-MM user interface to enable the EyeQ feature.

Related Information

Transceiver Reconfiguration Controller chapter of the Altera Transceiver PHY IP Core User Guide.
For information about enabling the EyeQ feature.

Adaptive Equalization

Adaptive equalization (AEQ) solves issues related to changing data rates and backplane losses.

High-speed interface systems require different equalization settings to compensate for changing data rates and backplane losses. Manual tuning of the receiver channel equalization stages involves finding the optimal settings through trial and error, and then locking in those values during compilation. This

manual static method is cumbersome and inefficient when system characteristics vary. The AEQ automatically tunes an active receiver channel equalization filter based on a frequency content comparison between the incoming signals and the internally generated reference signals.

Adaptive equalization is supported by Arria V GZ devices and not Arria V GX and GT devices.

The Transceiver Reconfiguration Controller provides an Avalon-MM user interface to enable the AEQ feature.

Related Information

"AEQ" section in the Transceiver Reconfiguration Controller chapter of the Altera Transceiver PHY IP Core User Guide
For information about enabling different options and using them to control the AEQ hardware.

Decision Feedback Equalization

Decision feedback equalization (DFE) helps compensate for backplane attenuation because of insufficient bandwidth.

DFE works by estimating the intersymbol interference (ISI) that is imposed by the channel on an incoming bit and canceling out the ISI as that bit is sampled by the CDR circuitry. The advantage of DFE is that it boosts the power of the highest frequency component of the received data without increasing its noise power. Use DFE in conjunction with the transmitter pre-emphasis and receiver linear equalization.

Decision feedback equalization is supported by Arria V GZ devices and not Arria V GX and GT devices.

Related Information

"DFE" section in the Transceiver Reconfiguration Controller chapter of the Altera Transceiver PHY IP Core User Guide
For more information about DFE.

Unsupported Reconfiguration Modes

The following reconfiguration modes are not supported:

- Switching between a receiver-only channel and a transmitter-only channel
- Switching between bonded to non-bonded mode or bonded mode with different xN lanes count (for example, switching from bonded x2 to bonded x4)
- Switching between one PHY IP to another PHY IP (for example Deterministic Latency PHY IP to Custom PHY IP)
- Switching between PMA Direct modes to non PMA Direct mode
- TX PLL reconfiguration is not supported if the TX PLL is connected to bonded channels

You can achieve PHY to PHY IP reconfiguration only if you use the Native PHY IP to configure your transceiver. For example, if you use the Native PHY IP to configure the SDI mode and a custom proprietary IP mode (also configured using Native PHY IP), you can reconfigure these two modes within the Native PHY IP. The switching refers to enabling and disabling the PCS sub-blocks for both SDI and the custom proprietary IP mode.

Document Revision History

Date	Version	Changes
September 2014	2014.09.30	Added FPGA fabric to transceiver channel interface width reconfiguration feature in *Table: Dynamic Reconfiguration Features.*
May 2013	2013.05.06	• Updated TX DCD calibration information • Included link AN 661 for fPLL reconfiguration • Added link to the known document issues in the Knowledge Base
November 2012	2012.11.19	• Rewritten and reorganized content, and updated template • Updated Transceiver Interface Reconfiguration • Added Reduced **.mif** Reconfiguration • Added On-Chip Signal Quality Monitoring (EyeQ) for Arria GZ devices • Adaptive Equalization for Arria GZ devices • Decision Feedback Equalization for Arria GZ devices • Listed unsupported features
June 2012	1.2	• Added "Transceiver PLL Reconfiguration" and "Transceiver Channel and Interface Reconfiguration" sections. • Updated the "Offset Cancellation and TX Duty Cycle Distortion Calibration" section • Updated Table 7–1

Date	Version	Changes
November 2011	1.1	• Added Table 7–1 • Deleted "Transceiver Reconfiguration Controller" and "Channel and PLL Reconfiguration" sections. • Updated "Offset Cancellation" and "PMA Analog Settings Reconfiguration" sections • Added "Enabling and Disabling Loopback Modes" section.

Introduction to the Arria V Hard Processor System

1

2014.12.15

av_5v4 Subscribe Send Feedback

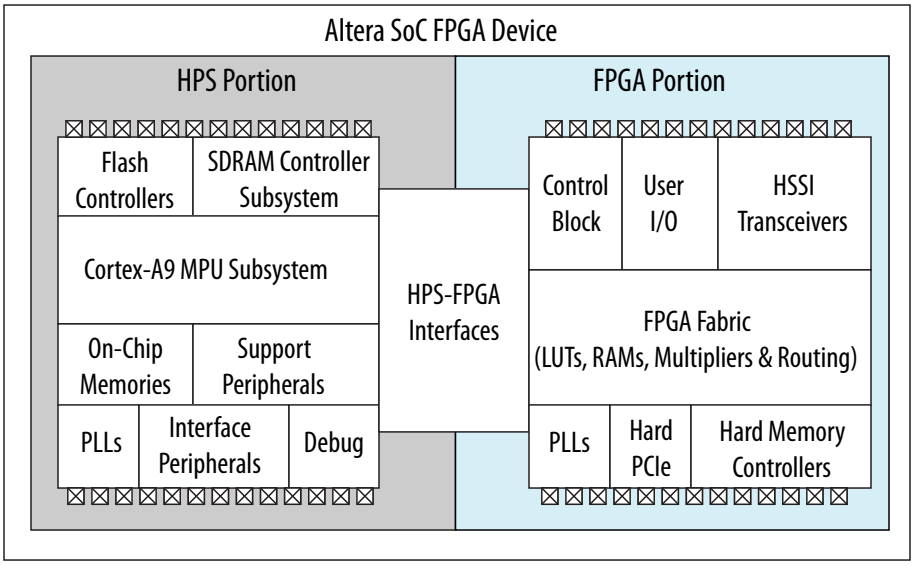
The Arria® V system-on-a-chip (SoC) is composed of two distinct portions- a dual-core ARM® Cortex™-A9 hard processor system (HPS) and an FPGA. The HPS architecture integrates a wide set of peripherals which reduce board size and increase performance within a system.

Figure 1-1 shows a high-level block diagram of the Altera® Arria V SoC device. Blocks connected to device pins have symbols (square with an X) adjacent to them in the figure.

The SoC features the following types of I/O pins:

- Dedicated I/O - I/O that is dedicated to an external non-volatile storage device (for boot flash), HPS clock and resets.
- Shared I/O - I/O that can be assigned to peripherals in the HPS or FPGA logic.
- FPGA I/O - I/O that is dedicated to the FPGA fabric. Some peripherals in the HPS can route signals to the FPGA fabric that may connect to the FPGA I/O instead of the shared I/O of the HPS portion of the device.

Figure 1-1: Altera SoC FPGA Device Block Diagram



The HPS contains:

- Microprocessor unit (MPU) subsystem with a dual ARM Cortex-A9 MPCore® processors
- Flash memory controllers
- SDRAM controller subsystem
- System interconnect
- On-chip memories
- Support peripherals
- Interface peripherals
- Debug capabilities
- Phase-locked loops (PLLs)

The dual-processor HPS supports symmetric (SMP) and asymmetric (AMP) multiprocessing.

The FPGA portion of the device contains:

- FPGA fabric
- Control block (CB)
- PLLs
- High-speed serial interface (HSSI) transceivers, depending on the device variant
- Hard PCI Express® (PCI-e) controllers
- Hard memory controllers

The HPS and FPGA communicate through bus interfaces that bridge the two distinct portions. On a power-on reset, the HPS can boot from multiple sources, including the FPGA fabric and external flash. The FPGA can be configured through the HPS or an externally supported device.

The HPS and FPGA portions of the device each have their own pins. Pins are not freely shared between the HPS and the FPGA fabric. The HPS I/O pins are configured by boot software executed by the MPU in the HPS.. Software executing on the HPS accesses control registers in the system manager to assign HPS I/O pins to the available HPS modules. The FPGA I/O pins are configured by an FPGA configuration image through the HPS or any external source supported by the device.

The MPU subsystem can boot from flash devices connected to the HPS pins. When the FPGA portion is configured by an external source, the MPU subsystem can boot from flash memory devices available to the FPGA portion of the device.

The HPS and FPGA portions of the device have separate external power supplies and independently power on. You can power on the HPS without powering on the FPGA portion of the device. However, to power on the FPGA portion, the HPS must already be on or powered at the same time as the FPGA portion. You can also turn off the FPGA portion of the device while leaving the HPS power on.

The HPS incorporates third-party intellectual property (IP) from several vendors.

Related Information

  For information about the FPGA portion of the device, refer to *Arria V Device Overview*.
- **Hard Processor System I/O Pin Multiplexing**
- **Booting and Configuration** on page 29-1

Features of the HPS

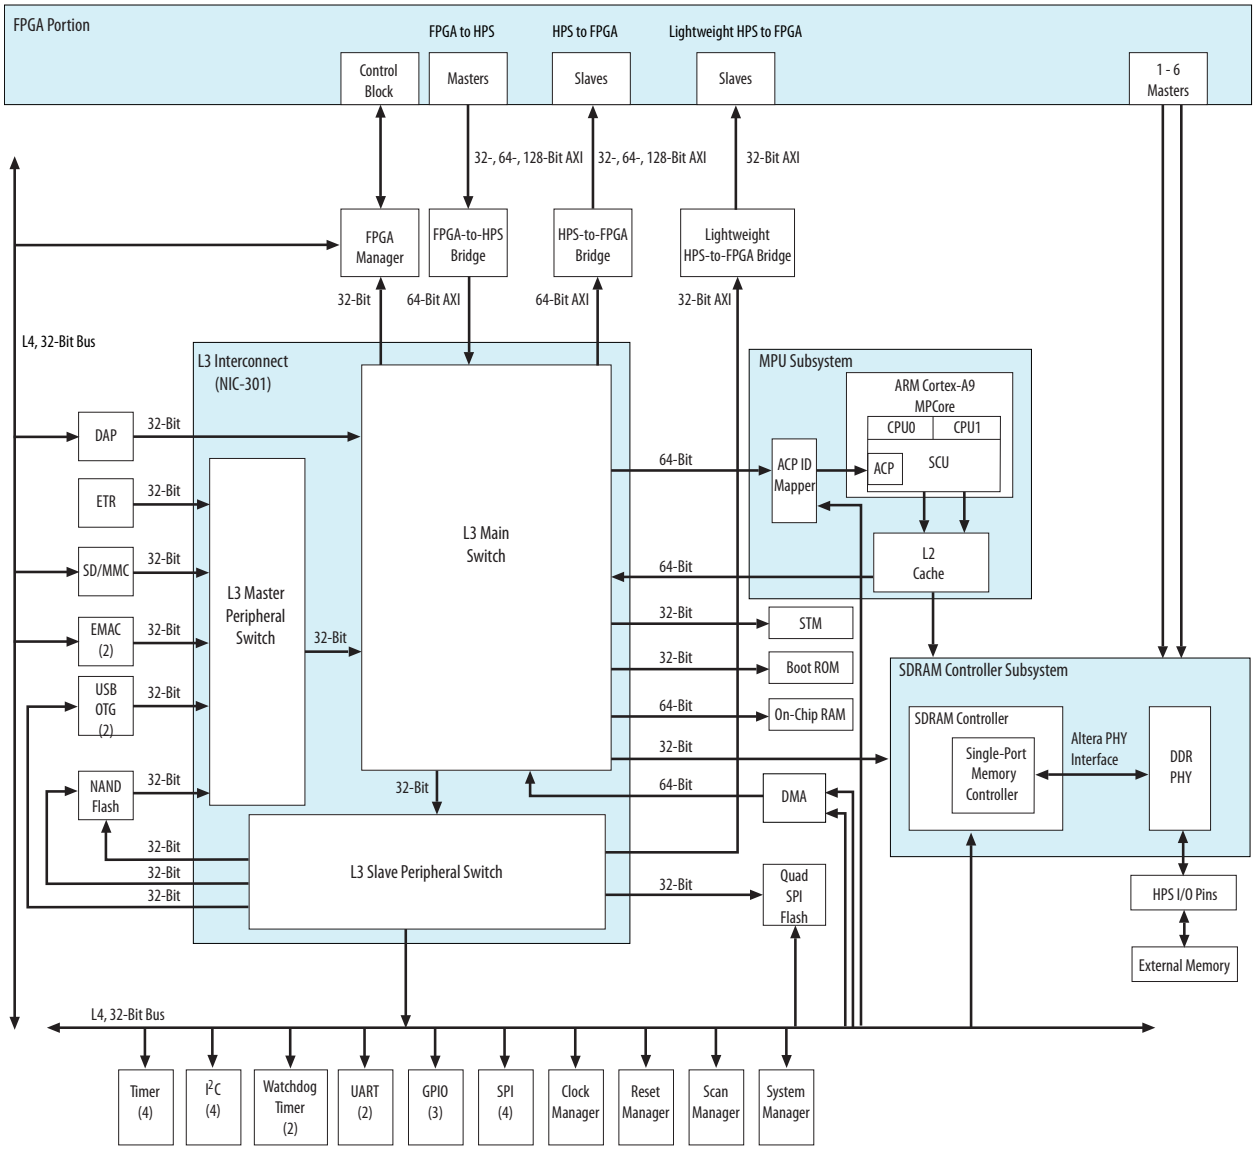
The following list contains the main modules of the HPS:

- MPU subsystem featuring a dual ARM Cortex-A9 MPCore processors
- General-purpose direct memory access (DMA) controller
- Two Ethernet media access controllers (EMACs)
- Two USB 2.0 on-the-go (OTG) controllers
- NAND flash controller
- Quad SPI flash controller
- Secure digital/multimedia card (MMC) controller
- Two serial peripheral interface (SPI) master controllers
- Two SPI slave controllers
- Four inter-integrated circuit (I^2C) controllers
- 64 KB on-chip RAM
- 64 KB on-chip boot ROM
- Two UARTs
- Four timers
- Two watchdog timers
- Three general-purpose I/O (GPIO) interfaces
- ARM Coresight™ debug components
- - Debug access port (DAP)
  - Trace port interface unit (TPIU)
  - System trace macrocell (STM)
  - Program trace macrocell (PTM)
  - Embedded trace router (ETR)
  - Embedded cross trigger (ECT)
- System manager
- Clock manager
- Reset manager
- Scan manager
- FPGA manager

HPS Block Diagram and System Integration

HPS Block Diagram

Figure 1-2: HPS Block Diagram



MPU Subsystem

The MPU subsystem provides the following functionality:

- ARM Cortex-A9 MPCore
  - Two ARM Cortex-A9 processors
  - NEON™ single instruction, multiple data (SIMD) coprocessor and vector floating-point v3 (VFPv3) per processor
  - Snoop control unit (SCU) to ensure coherency
  - Accelerator coherency port (ACP) that accepts coherency memory access requests
  - Interrupt controller
  - One general-purpose timer and one watchdog timer per processor
  - Debug and trace features
  - 32 KB instruction and 32 KB data level 1 (L1) caches per processor
  - Memory management unit (MMU) per processor
- ARM L2-310 level 2 (L2) cache
  - Shared 512 KB L2 cache
- ACP ID mapper
  - Maps the 12-bit ID from the level 3 (L3) interconnect to the 3-bit ID supported by the ACP

A programmable address filter in the L2 cache controls which portions of the 32-bit physical address space use each master.

Related Information

CoreSight Debug and Trace

The CoreSight debug and trace system offers the following features:

- Real-time program flow instruction trace through a separate PTM for each processor
- Host debugger JTAG interface
- Connections for cross-trigger and STM-to-FPGA interfaces, which enable soft IP generation of triggers and system trace messages
- Custom message injection through STM into trace stream for delivery to host debugger
- Capability to route trace data to any slave accessible to the ETR AXI master connected to the level 3 (L3) interconnect

System Interconnect

The system interconnect consists of the main L3 interconnect and level 4 (L4) buses. The L3 interconnect is an ARM NIC-301 module composed of the following switches:

- L3 main switch
  - Connects the master, slaves, and other subswitches
  - Provides 64-bit switching capabilities
- L3 master peripheral switch
  - Connects master ports of peripherals with integrated DMA controllers to the L3 main switch
- L3 slave peripheral switch
  - Connects slave ports of peripherals to the L3 main switch

The L4 buses are each connected to a master in the L3 slave peripheral switch.

- Each L4 bus is 32 bits wide and is connected to multiple slaves.
- Each L4 bus operates on a separate clock source.

Related Information

System Interconnect on page 7-1
For more information regarding SDRAM address mapping, please refer to the System Interconnect chapter.

Memory Controllers

SDRAM Controller Subsystem

HPS and FPGA fabric masters have access to the SDRAM controller subsystem.

The SDRAM controller subsystem implements the following high-level features:

- Support for double data rate 2 (DDR2), DDR3, and low-power double data rate 2 (LPDDR2) devices
- Error correction code (ECC) support, including calculation, single-bit error correction and write-back, and error counters
- Fully-programmable timing parameter support for all JEDEC-specified timing parameters
- All ports support memory protection and mutual accesses
- Quality of Service (QoS) for the fabric interfaces

The SDRAM controller subsystem is composed of the SDRAM controller and the DDR PHY.

Related Information

SDRAM Controller Subsystem on page 11-1

SDRAM Controller

The SDRAM controller contains a multiport front end (MPFE) that accepts requests from HPS masters and from soft logic in the FPGA fabric via the FPGA-to-HPS SDRAM interface.

The SDRAM controller offers the following features:

- Up to 4 GB address range
- 8-, 16-, and 32-bit data widths
- Optional ECC support
- Low-voltage 1.35V DDR3L and 1.2V DDR3U support
- Full memory device power management support
- Two chip selects (8- and 16-bit widths)

The SDRAM controller provides the following features to maximize memory performance:

- Command reordering (look-ahead bank management)
- Data reordering (out of order transactions)
-
- Priority arbitration and deficit round-robin arbitration for ports with the same priority
- High-priority bypass for latency sensitive traffic

SDRAM Controller Subsystem on page 11-1

DDR PHY

The DDR PHY interfaces the single port memory controller to the HPS memory I/O.

Related Information

SDRAM Controller Subsystem on page 11-1

NAND Flash Controller

The NAND flash controller is based on the Cadence® Design IP® NAND Flash Memory Controller and offers the following functionality and features:

- Supports one x8 NAND flash device
- Supports Open NAND Flash Interface (ONFI) 1.0
- Supports NAND flash memories from Hynix, Samsung, Toshiba, Micron, and ST Micro
- Supports programmable 512 byte (4-, 8-, or 16-bit correction) or 1024 byte (24-bit correction) ECC sector size
- Supports pipeline read-ahead and write commands for enhanced read/write throughput
- Supports devices with 32, 64, 128, 256, 384, or 512 pages per block
- Supports multiplane devices
- Supports page sizes of 512 bytes, 2 kilobytes (KB), 4 KB, or 8 KB
- Supports single-level cell (SLC) and multi-level cell (MLC) devices with programmable correction capabilities
- Provides internal DMA
- Provides programmable access timing

Related Information

NAND Flash Controller on page 13-1

Quad SPI Flash Controller

The quad SPI flash controller is based on the Cadence Quad SPI Flash Controller and offers the following features:

- Supports SPIx1, SPIx2, or SPIx4 (Quad SPI) serial NOR flash devices
- Supports direct access and indirect access modes
- Supports single, dual, and quad I/O instructions
- Support up to four chip selects
- Programmable write-protected regions
- Programmable delays between transactions
- Programmable device sizes
- Support eXecute-In-Place (XIP) mode
- Programmable baud rate generator to generate device clocks

Related Information

Quad SPI Flash Controller on page 15-1

SD/MMC Controller

The SD/MMC controller is based on Synopsys® DesignWare® Mobile Storage Host controller and offers the following features:

- Integrated descriptor-based DMA
- Supports CE-ATA digital protocol commands
- Supports single card
- Single data rate (SDR) mode only
- Programmable card width: 1-, 4-, and 8-bit
- Programmable card types: SD, SDIO, or MMC
- Up to 64 KB programmable block size
- Supports the following standards and card types:
  - SD, including eSD—version 3.0(1)
  - SDIO, including embedded SDIO (eSDIO)—version 3.0(2)
  - CE-ATA—version 1.1
- Supports various types of multimedia cards, MMC version 4.41(3)
  - MMC: 1-bit data bus
  - Reduced-size MMC (RSMMC): 1-bit and 4-bit data bus
  - MMCMobile: 1-bit data bus
  - MMCPlus: 1-bit, 4-bit, and 8-bit data bus
  - Default speed and high speed
- Supports embedded MMC (eMMC) version 4.41(4)
  - 1-bit and 4-bit data bus

Note: For an inclusive list of the programmable card types versions supported, refer to the *SD/MMC Controller* chapter.

(1) Does not support SDR50, SDR104, and DDR50 modes.
(2) Does not support SDR50, SDR104, and DDR50 modes.
(3) Does not support DDR mode.
(4) Does not support DDR mode.

SD/MMC Controller on page 14-1

Support Peripherals

Clock Manager

The clock manager offers the following features:

- Manages clocks for HPS
- Supports dynamic clock tuning

Related Information

Clock Manager on page 2-1

Reset Manager

The reset manager manages both hardware and software reset sources in the HPS. Reset status is also provided. Reset types include cold, warm, and debug. Reset behavior depends on the type.

Related Information

- **Reset Manager** on page 3-1
- **Security Manager**

System Manager

The system manager controls system functions and modules that need external control signals. The system manager offers the following features:

- ECC monitoring and control
- Pin multiplexing
- Low-level control of peripheral features not accessible through the control and status registers (CSRs)
- Freeze controller that places I/O elements into a safe state for configuration

Related Information

System Manager on page 5-1

Scan Manager

The scan manager is used to configure and manage HPS I/O pins and to communicate with the FPGA JTAG.

Related Information

Scan Manager on page 6-1

Timers

The four timers are based on the Synopsys DesignWare APB Timer peripheral and offer the following features:

- 32-bit timer resolution
- Free-running timer mode
- Programmable time-out period up to approximately 86 seconds (assuming a 50 MHz input clock frequency)
- Interrupt generation

Related Information

Timer on page 23-1

Watchdog Timers

The two watchdog timers are based on the Synopsys DesignWare APB Watchdog Timer peripheral and offer the following features:

- 32-bit timer resolution
- Interrupt request
- Reset request
- Programmable time-out period up to approximately 86 seconds (assuming a 50 MHz input clock frequency)

Related Information

Watchdog Timer on page 24-1

DMA Controller

The DMA controller provides high-bandwidth data transfers for modules without integrated DMA controllers. The DMA controller is based on the ARM Corelink™ DMA Controller (DMA-330) and offers the following features:

- Micro-coded to support flexible transfer types
  - Memory-to-memory
  - Memory-to-peripheral
  - Peripheral-to-memory
  - Scatter-gather
- Supports up to eight channels
- Supports flow control with 31 peripheral handshake interfaces
- Software can schedule up to 16 outstanding read and 16 outstanding write instructions
- Supports nine interrupt lines: one for DMA thread abort and eight for external events

Related Information

DMA Controller on page 16-1

FPGA Manager

The FPGA manager offers the following features:

- Manages configuration of the FPGA portion of the device
- 32-bit fast passive parallel configuration interface to the FPGA CSS block
- Partial reconfiguration
- Compressed FPGA configuration images
- Advanced Encryption Standard (AES) encrypted FPGA configuration images
- Monitors configuration-related signals in FPGA
- Provides 32 general-purpose inputs and 32 general-purpose outputs to the FPGA fabric

Related Information

FPGA Manager on page 4-1

Interface Peripherals

EMACs

The two EMACs are based on the Synopsys Designware 3504-0 Universal 10/100/1000 Ethernet MAC and offer the following features:

- Supports 10, 100, and 1000 Mbps standard
- Supports RGMII external PHY interface
  - Media independent interface (MII)
  - Gigabit media independent interface (GMII)
  - Reduced media independent interface (RMII)
  - Reduced gigabit media independent interface (RGMII)
  - Serial gigabit media independent interface (SGMII) with additional external conversion logic
- Provides full GMII interface when using FPGA interface
- Integrated DMA controller
- Supports IEEE 1588-2002 and IEEE 1588-2008 standards for precision networked clock synchronization
- Supports IEEE 802.1Q VLAN tag detection for reception frames
- Supports a variety of address filtering modes
- Management of PHY through Management data input/output (MDIO) interface or optionally, I^2C interface

Related Information

Ethernet Media Access Controller on page 17-1

USB Controllers

The HPS provides two USB 2.0 Hi-Speed OTG controllers from Synopsys DesignWare and offer the following features:

- Complies with both Revision 1.3 and Revision 2.0 of the "On the Go and Embedded Host Supplement to the USB Revision 2.0 Specification
- Supports software-configurable modes of operation between OTG 1.3 and OTG 2.0
- Supports all USB 2.0 speeds:
  - High speed (HS, 480-Mbps)
  - Full speed (FS, 12-Mbps)
  - Low speed (LS, 1.5-Mbps)
- Local buffering with error correction code (ECC) support
- Supports USB 2.0 Transceiver Macrocell Interface Plus (UTMI+) Low Pin Interface (ULPI) PHYs (SDR mode only)
- Supports up to 16 bidirectional endpoints, including control endpoint 0
- Supports up to 16 host channels
- Supports generic root hub
- Supports automatic ping capability

Related Information

- **USB 2.0 OTG Controller** on page 18-1
- **Universal Serial Bus (USB) website**
  Additional information is available in the On The Go and Embedded Host Supplement to the USB Revision 2.0 Specification, which you can download from the USB Implementers Forum website.

I^2C Controllers

The four I^2C controllers are based on Synopsys DesignWare APB I^2C controller and offer the following features:

- Two controllers support I^2C management interfaces for use by the EMAC controllers
- Support both 100 KBps and 400 KBps modes
- Support both 7-bit and 10-bit addressing modes
- Support master and slave operating mode
- Direct access for host processor
- DMA controller may be used for large transfers

Related Information

I2C Controller on page 20-1

UARTs

The two UART modules are based on Synopsys DesignWare APB Universal Asynchronous Receiver/ Transmitter peripheral and offer the following features:

- 16550-compatible UART
- Support automatic flow control as specified in 16550 specification
- Programmable baud rate up to 6.25 MBaud (with 100MHz reference clock)
- Direct access for host processor

- DMA controller may be used for large transfers
- 128-byte transmit and receive FIFO buffers
- Separate thresholds for DMA request and handshake signals to maximize throughput

Related Information

UART Controller on page 21-1

SPI Master Controllers

The two SPI master controllers are based on Synopsys DesignWare Synchronous Serial Interface (SSI) controller and offer the following features:

- Choice of Motorola SPI, Texas Instruments Synchronous Serial Protocol or National Semiconductor Microwire mode
- Programmable data frame size from 4 to 16 bits
- Supports full- and half-duplex modes
- Supports up to four chip selects
- Direct access for host processor
- DMA controller may be used for large transfers
- Programmable master serial bit rate
- Support for `rxd` sample delay
- Transmit and receve FIFO buffers are 256 words deep

Related Information

SPI Controller on page 19-1

SPI Slave Controllers

The two SPI slave controllers are based on Synopsys DesignWare Synchronous Serial Interface (SSI) controller and offer the following features:

- Programmable data frame size from 4 to 16 bits
- Supports full- and half-duplex moces
- Direct access for host processor
- DMA controller may be used for large transfers
- Transmit and receive FIFO buffers are 256 words deep

Related Information

SPI Controller on page 19-1

GPIO Interfaces

The HPS provides three GPIO interfaces that are based on Synopsys DesignWare APB General Purpose Programming I/O peripheral and offer the following features:

- Supports digital de-bounce
- Configurable interrupt mode
- Supports up to 71 I/O pins and 14 input-only pins, based on device variant

Related Information

General-Purpose I/O Interface on page 22-1

On-Chip Memory

On-Chip RAM

The on-chip RAM offers the following features:

- 64 KB size
- 64-bit slave interface
- High performance for all burst lengths

Related Information

On-Chip Memory on page 12-1

Boot ROM

The boot ROM offers the following features:

- 64 KB size
- Contains the code required to support HPS boot from cold or warm reset
- Used exclusively for booting the HPS

Related Information

On-Chip Memory on page 12-1

Endian Support

The HPS is natively a little-endian system. All HPS slaves are little-endian.

The processor masters are software configurable to interpret data as little-endian or big-endian, byte-invariant (BE8). All other masters, including the USB 2.0 interface, are little-endian.

The FPGA-to-HPS, HPS-to-FPGA, FPGA-to-SDRAM, and lightweight HPS-to-FPGA interfaces are little-endian.

If a processor is set to BE8 mode, software must convert endianness for accesses to peripherals and DMA linked lists in memory.

The ARM Cortex-A9 MPU supports a single instruction to change the endianness of the processor and provides the REV and REV16 instructions to swap the endianness of bytes or half-words respectively. The MMU page tables are software configurable to be organized as little-endian or BE8.

The ARM DMA controller is software configurable to perform byte lane swapping during a transfer.

HPS-FPGA Interfaces

The HPS-FPGA interfaces provide a variety of communication channels between the HPS and the FPGA fabric. The HPS-FPGA interfaces include:

- FPGA-to-HPS bridge—a high-performance bus with a configurable data width of 32, 64, and 128 bits, allowing the FPGA fabric to master transactions to the slaves in the HPS. This interface allows the FPGA fabric to have full visibility into the HPS address space. This interface also provides access to the coherent memory interface.
- HPS-to-FPGA bridge—a high-performance interface with a configurable data width of 32, 64, and 128 bits, allowing the HPS to master transactions to slaves in the FPGA fabric.
- Lightweight HPS-to-FPGA bridge—an interface with a 32-bit fixed data width, allowing the HPS to master transactions to slaves in the FPGA fabric. This lower-bandwidth interface is useful for accessing the control and status registers of soft peripherals.
- FPGA clocks and resets
- HPS-to-FPGA JTAG—allows the HPS to master the FPGA JTAG chain.
- TPIU trace—sends trace data created in the HPS to the FPGA fabric.
- FPGA System Trace Macrocell (STM) —an interface that allows the FPGA fabric to send hardware events stored in the HPS trace using STM.
- FPGA cross-trigger—an interface that allows triggers to and from the CoreSight trigger system.
- DMA peripheral interface—multiple peripheral-request channels.
- FPGA manager interface—signals that communicate with the FPGA fabric for boot and configuration.
- Interrupts—allow soft IP to supply interrupts directly to the MPU interrupt controller.
- MPU standby and events—signals that notify the FPGA fabric that the MPU is in standby mode and signals that wake up Cortex-A9 processors from a wait for event (WFE) state.
- HPS debug interface - an interface that allows the HPS debug control domain (debug APB) to extend into FPGA

Related Information

HPS-FPGA Bridges on page 8-1

HPS Address Map

The address map specifies the addresses of slaves, such as memory and peripherals, as viewed by the MPU and other masters. The HPS has multiple address spaces, defined in the following section.

HPS Address Spaces

The following table shows the HPS address spaces and their sizes.

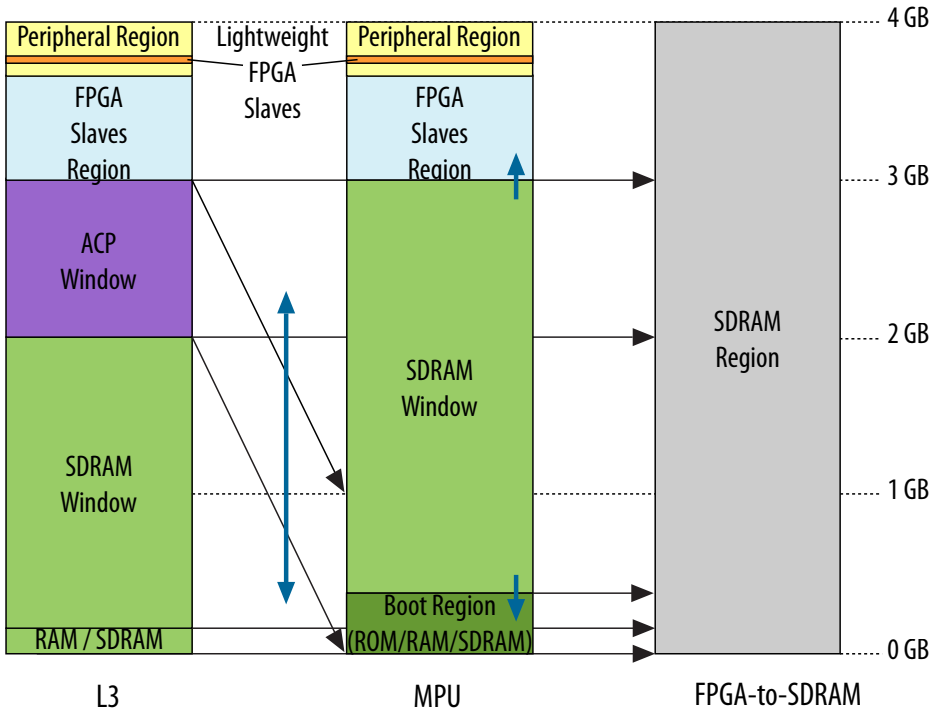
Table 1-1: HPS Address Spaces

Name	Description	Size
MPU	MPU subsystem	4 GB
L3	System interconnect	4 GB
SDRAM	SDRAM region	4 GB

Address spaces are divided into one or more nonoverlapping regions. For example, the MPU address space has the peripheral, FPGA slaves, SDRAM window, and boot regions.

The following figure shows the relationships between the HPS address spaces. The figure is not to scale.

Figure 1-3: HPS Address Space Relationships



The window regions provide access to other address spaces. The thin black arrows indicate which address space is accessed by a window region (arrows point to accessed address space). For example, accesses to the ACP window in the L3 address space map to a 1 GB region of the MPU address space.

The SDRAM window in the MPU address space can grow and shrink at the top and bottom (short, blue vertical arrows) at the expense of the FPGA slaves and boot regions. For specific details, refer to "MPU Address Space".

The ACP window can be mapped to any 1 GB region in the MPU address space (blue vertical bidirectional arrow), on gigabyte-aligned boundaries.

The following table shows the base address and size of each region that is common to the L3 and MPU address spaces.

Table 1-2: Common Address Space Regions

Identifier	Region Name	Base Address	Size
FPGASLAVES	FPGA slaves	0xC0000000	960 MB
PERIPH	Peripheral	0xFC000000	64 MB
LWFPGASLAVES (5)	Lightweight FPGA slaves	0xFF200000	2 MB

SDRAM Address Space

The SDRAM address space is up to 4 GB. The entire address space can be accessed through the FPGA-to-HPS SDRAM interface from the FPGA fabric. The total amount of SDRAM addressable from the other address spaces can be configured at runtime.

Related Information

System Interconnect on page 1-6
For details of how to configure the SDRAM address space.

MPU Address Space

The MPU address space is 4 GB and applies to addresses generated inside the MPU. The MPU address space contains the following regions:

- The SDRAM window region provides access to a large, configurable portion of the 4 GB SDRAM address space.
- The MPU L2 cache controller contains a master connected to the system interconnect and a master connected to the SDRAM.
- The address filtering start and end registers in the L2 cache controller define the SDRAM window boundaries.
  - The boundaries are megabyte-aligned.
  - Addresses within the boundaries route to the SDRAM master.
  - Addresses outside the boundaries route to the system interconnect master.

Clock Manager 2

2014.12.15

av_5v4

The hard processor system (HPS) clock generation is centralized in the clock manager. The clock manager is responsible for providing software-programmable clock control to configure all clocks generated in the HPS. Clocks are organized in clock groups. A clock group is a set of clock signals that originate from the same clock source. A phase-locked loop (PLL) clock group is a clock group where the clock source is a common PLL voltage-controlled oscillator (VCO).

Features of the Clock Manager

The *Clock Manager* offers the following features:

- Generates and manages clocks in the HPS
- Contains the following PLL clock groups:
  - Main—contains clocks for the Cortex-A9 microprocessor unit (MPU) subsystem, level 3 (L3) interconnect, level 4 (L4) peripheral bus, and debug
  - Peripheral—contains clocks for PLL-driven peripherals
  - SDRAM—contains clocks for the SDRAM subsystem
- Allows scaling of the MPU subsystem clocks without disabling peripheral and SDRAM clock groups
- Generates clock gate controls for enabling and disabling most clocks
- Initializes and sequences clocks for the following events:
  - Cold reset
  - Safe mode request from reset manager on warm reset
- Allows software to program clock characteristics, such as the following items discussed later in this chapter:
  - Input clock source for SDRAM and peripheral PLLs
  - Multiplier range, divider range, and six post-scale counters for each PLL
  - Output phases for SDRAM PLL outputs
  - VCO enable for each PLL
  - Bypass modes for each PLL
  - Gate off individual clocks in all PLL clock groups
  - Clear loss of lock status for each PLL
  - Safe mode for hardware-managed clocks
  - General-purpose I/O (GPIO) debounce clock divide

- Allows software to observe the status of all writable registers
- Supports interrupting the MPU subsystem on PLL-lock and loss-of-lock
- Supports clock gating at the signal level

The *Clock Manager* is **not** responsible for the following functional behaviors:

- Selection or management of the clocks for the FPGA-to-HPS and HPS-to-FPGA interfaces. The FPGA logic designer is responsible for selecting and managing these clocks.
- Software must not program the *Clock Manager* with illegal values. If it does, the behavior of the clock manager is undefined and could stop the operation of the HPS. The only guaranteed means for recovery from an illegal clock setting is a cold reset.
- When re-programming clock settings, there are no automatic glitch-free clock transitions. Software must follow a specific sequence to ensure glitch-free clock transitions. Refer to *Hardware-Managed and Software-Managed Clocks* section of this chapter.

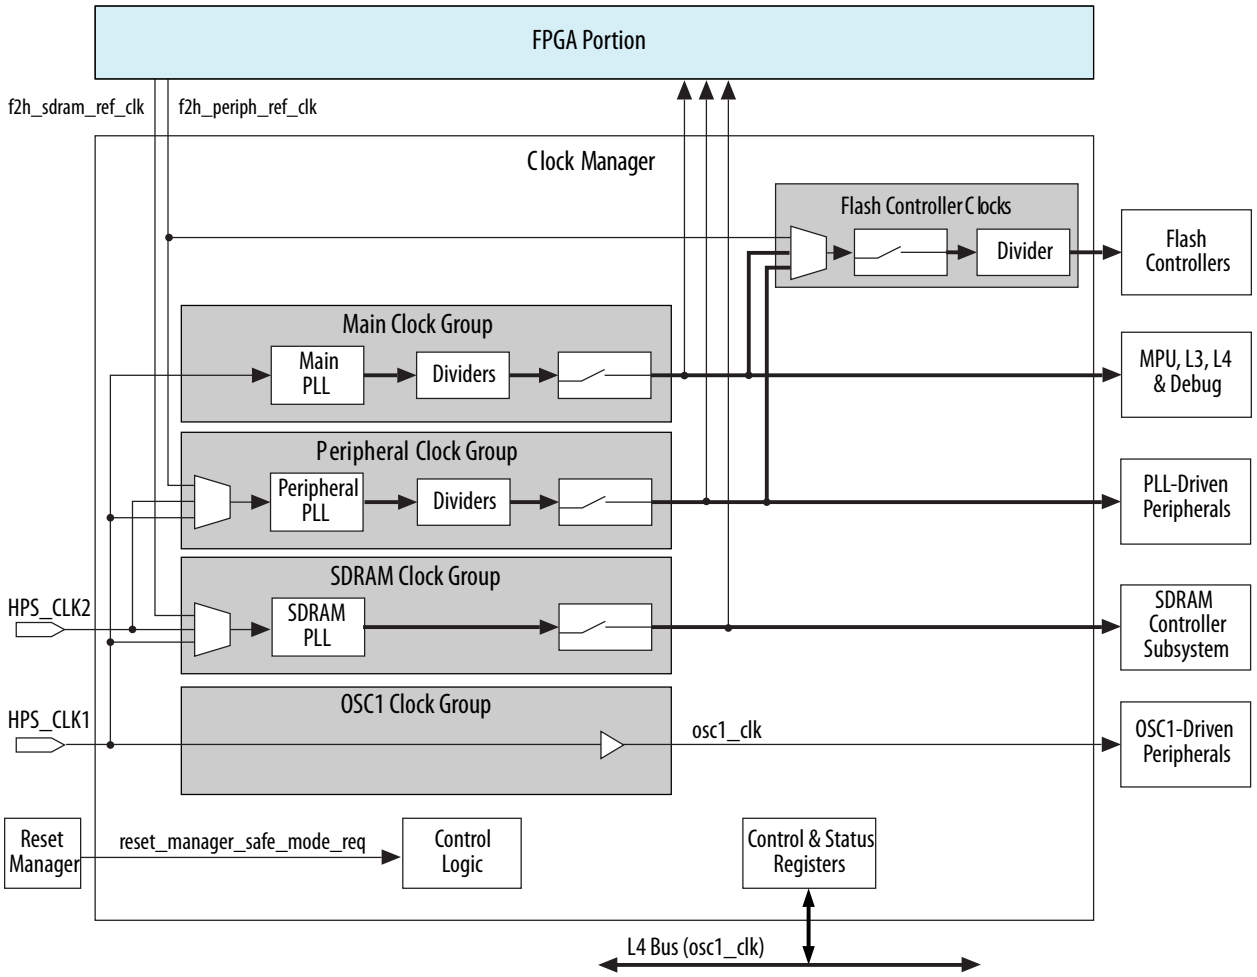
Related Information

Hardware-Managed and Software-Managed Clocks on page 2-5

Clock Manager Block Diagram and System Integration

Figure 2-1: Clock Manager Block Diagram

The following figure shows the major components of the clock manager and its integration in the HPS.



Functional Description of the Clock Manager

Clock Manager Building Blocks

PLLs

The *Clock Manager* contains three PLLs: main, peripherals, and SDRAM. These PLLs generate the majority of clocks in the HPS. There is no phase control between the clocks generated by the three PLLs.

Each PLL has the following features:

- Phase detector and output lock signal generation
- Registers to set VCO frequency
  - (M) Multiplier range is 1 to 4096
  - (N) Divider range is 1 to 64
- Six post-scale counters (C0-C5) with a range of 1 to 512
- PLL can be enabled to bypass all outputs to the `osc1_clk` clock for glitch-free transitions

The SDRAM PLL has the following additional feature:

- Phase shift of 1/8 per step
  - Phase shift range is 0 to 7

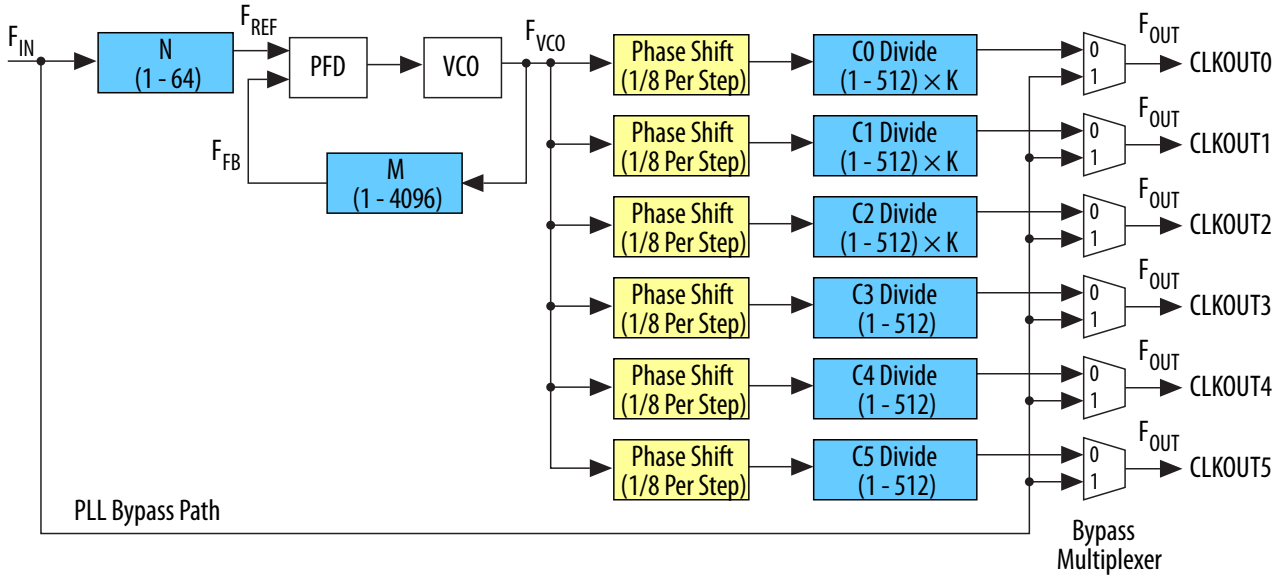
Related Information

Arria V Device Datasheet

FREF, FVCO, and FOUT Equations

Figure 2-2: PLL Block Diagram

Values listed for M, N, and C are actually one greater than the values stored in the CSRs.



$$FREF = F_{IN} / N$$
$$FVCO = F_{REF} \times M = F_{IN} \times M/N$$
$$FOUT = F_{VCO} / (C_i \times K) = F_{REF} \times M/ (C_i \times K) = (F_{IN} \times M)/ (N \times C_i \times K)$$

Table 2-1: FREF, FVCO, and FOUT Equation variables

Variable	Value	Description
FVC	= VCO frequency	-
FIN	= Input frequency	-
FREF	= Reference frequency	-
C_i	= Post-scale counter	i is 0-5 for each of the six counters
K	= Internal post-scale counter in main PLL	reset values are K = 2 for C0 K=4 for C1 and C2

Variable	Value	Description
M	= numer + 1	Part of clock feedback path. VCO register is used to program M value. (Range 1 to 4096)
N	= denom + 1	Part of input clock path. VCO register is used to program N value. (Range 0 to 64)

Note: The reset values of numer and denom are 1 so that at reset, the M value is 2 and the N value is 2.

The vco register is used to program the M and N values. In the table below you can see which sections of the vco bit field are used to set the values of M and N.

Table 2-2: VCO Register

Name	Bit	Reset	Range	Description
numer	3:15	0x1	0 to 4095	Numerator in VCO output frequency equation. **Note:** Bit 15 reserved.
denom	16:21	0x1	0 to 63	Denominator in VCO output frequency equation.

Related Information

Clock Manager Address Map and Register Definitions on page 2-22
For the full bit field of the vco register, refer to the Address Map and Register Definitions section.

Dividers

Dividers subdivide the C0-C15 clocks produced by the PLL to lower frequencies. The main PLL C0-C2 clocks have an additional internal post-scale counter.

Clock Gating

Clock gating enables and disables clock signals.

Control and Status Registers

The *Clock Manager* contains registers used to configure and observe the clock manager.

Hardware-Managed and Software-Managed Clocks

When changing values on clocks, the terms *Hardware-Managed* and *Software-Managed* define who is responsible for successful transitions. Software-Managed clocks require that software manually gate any clock affected by the change, wait for any PLL lock if required, then ungate the clocks. Hardware-Managed clocks use hardware to ensure that a glitch-free transition to a new clock value occurs. There are

three Hardware-Managed sets of clocks in the HPS, namely, clocks generated from the main PLL outputs C0, C1, and C2. All other clocks in the HPS are Software-Managed clocks.

Clock Groups

The clock manager contains one clock group for each PLL and one clock group for the HPS_CLK1 pin.

HPS_CLK1 and HPS_CLK2 are powered by the HPS reset and clock input pins power supply ($V_{CCRSTCLK}$_HPS). For more information on $V_{CCRSTCLK}$_HPS refer to the Arria V Device Datasheet.

Related Information

Arria V Device Datasheet

OSC1 Clock Group

The clock in the OSC1 clock group is derived directly from the HPS_CLK1 pin. This clock is never gated or divided.

HPS_clk1 is used as a PLL input and also by HPS logic that does not operate on a clock output from a PLL.

Table 2-3: OSC1 Clock Group Clock

Name	Frequency	Clock Source	Destination
osc1_clk	10 to 50 MHz	HPS_CLK1 pin	OSC1-driven peripherals. Refer to "Main Clock Group Clocks".

Main Clock Group

The main clock group consists of a PLL, dividers, and clock gating. The clocks in the main clock group are derived from the main PLL. The main PLL is always sourced from the HPS_CLK1 pin of the device.

Table 2-4: Main PLL Output Assignments

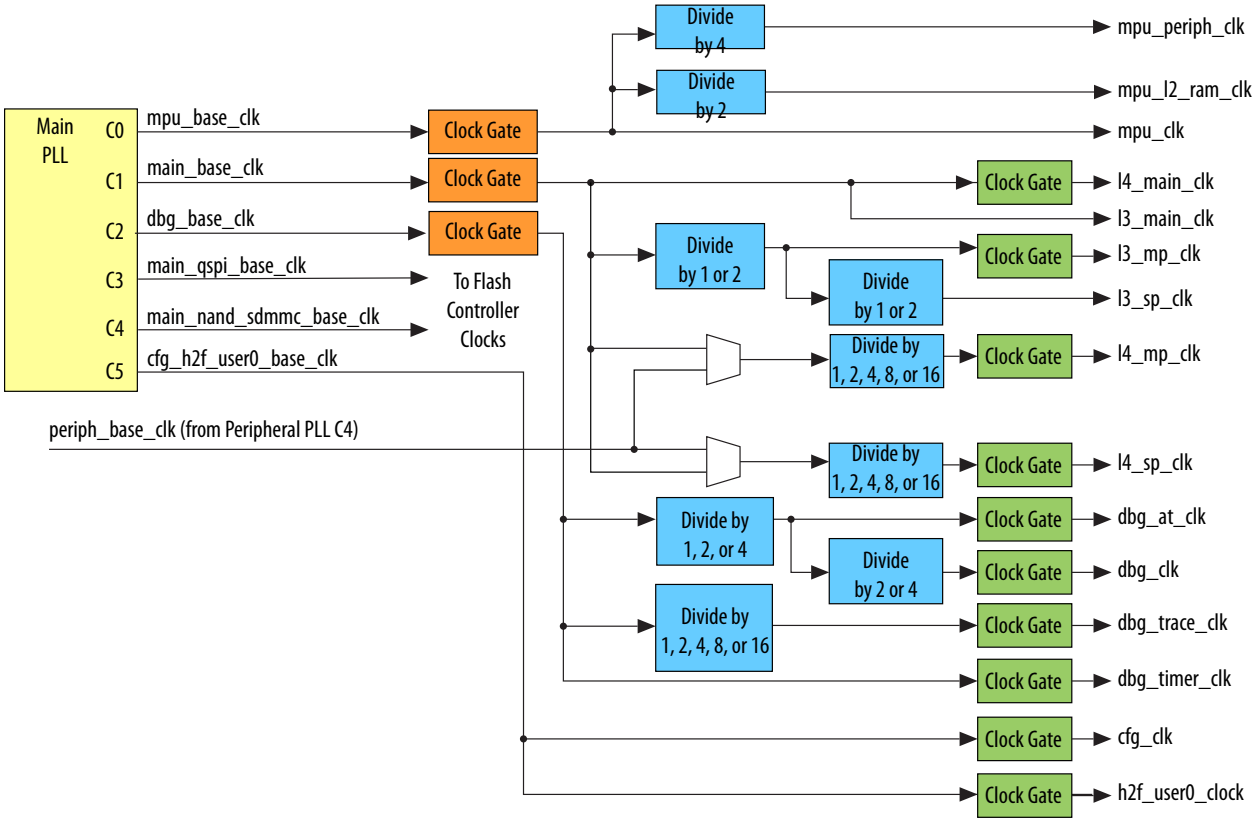
PLL	Output Counter	Clock Name	Frequency	Phase Shift Control
Main	C0	mpu_base_clk	osc1_clk to varies (6)	No
	C1	main_base_clk	osc1_clk to varies (6)	No
	C2	dbg_base_clk	osc1_clk/4 to mpu_base_clk/2	No
	C3	main_qspi_base_clk	Up to 432 MHz	No
	C4	main_nand_sdmmc_base_clk	Up to 250 MHz for the NAND flash controller and up to 200 MHz for the SD/MMC controller	No
	C5	cfg_h2f_user0_base_clk	osc1_clk to 125 MHz for driving configuration and 100 MHz for the user clock	No

The counter outputs from the main PLL can have their frequency further divided by programmable dividers external to the PLL. Transitions to a different divide value occur on the fastest output clock, one clock cycle prior to the slowest clock's rising edge. For example the clock transitions on cycle 15 of the divide-by-16 divider for the main C2 output and cycle 3 of the divide-by-4 divider for the main C0 output.

The following figure shows how each counter output from the main PLL can have its frequency further divided by programmable post-PLL dividers. Green-colored clock gating logic is directly controlled by software writing to a register. Orange-colored clock gating logic is controlled by hardware. Orange-colored clock gating logic allows hardware to seamlessly transition a synchronous set of clocks, for example, all the MPU subsystem clocks.

(6) The maximum frequency depends on the speed grade of the device.

Figure 2-3: Main Clock Group Divide and Gating



The clocks derived from main PLL C0-C2 outputs are hardware-managed, meaning hardware ensures that a clean transition occurs, and can have the following control values changed dynamically by software write accesses to the control registers:

- PLL bypass
- PLL numerator, denominator, and counters
- External dividers

For these registers, hardware detects that the write has occurred and performs the correct sequence to ensure that a glitch-free transition to the new clock value occurs. These clocks can pause during the transition.

Table 2-5: Main Clock Group Clocks

System Clock Name	Frequency	Constraints and Notes
`mpu_clk`	Main PLL C0	Clock for MPU subsystem, including CPU0 and CPU1
`mpu_l2_ram_clk`	`mpu_clk/2`	Clock for MPU level 2 (L2) RAM

System Clock Name	Frequency	Constraints and Notes
mpu_periph_clk	mpu_clk/4	Clock for MPU snoop control unit (SCU) peripherals, such as the general interrupt controller (GIC)
l3_main_clk	Main PLL C1	Clock for L3 main switch
l3_mp_clk	l3_main_clk or l3_main_clk/2	Clock for L3 master peripherals (MP) switch
l3_sp_clk	l3_mp_clk or l3_mp_clk/2	Clock for L3 slave peripherals (SP) switch
l4_main_clk	Main PLL C1	Clock for L4 main bus
l4_mp_clk	osc1_clk/16 to 100 MHz divided from main PLL C1 or peripheral PLL C4	Clock for L4 MP bus
l4_sp_clk	osc1_clk/16 to 100 MHz divided from main PLL C1 or peripheral PLL C4	Clock for L4 SP bus
dbg_at_clk	osc1_clk/4 to main PLL C2/2	Clock for CoreSight™ debug trace bus
dbg_trace_clk	osc1_clk/16 to main PLL C2	Clock for CoreSight™ debug Trace Port Interface Unit (TPIU)
dbg_timer_clk	osc1_clk to main PLL C2	Clock for the trace timestamp generator
dbg_clk	dbg_at_clk/2 or dbg_at_clk/4	Clock for Debug Access Port (DAP) and debug peripheral bus
main_qspi_clk	Main PLL C3	Quad SPI flash internal logic clock
main_nand_sdmmc_clk	Main PLL C4	Input clock to flash controller clocks block
cfg_clk	osc1_clk to 125_MHz divided from main PLL C5	FPGA manager configuration clock
h2f_user0_clock	osc1_clk to 100_MHz divided from main PLL C5	Auxiliary user clock to the FPGA fabric

Changing Values That Affect Main Clock Group PLL Lock

To change any value that affects the VCO lock of the main clock group PLL including the hardware-managed clocks, software must put the main PLL in bypass mode, which causes all the main PLL output clocks to be driven by the `osc1_clk` clock. Software must detect PLL lock by reading the lock status register prior to taking the main PLL out of bypass mode.

Once a PLL is locked, changes to any PLL VCO frequency that are 20 percent or less do not cause the PLL to lose lock. Iteratively changing the VCO frequency in increments of 20 percent or less allow a slow ramp of the VCO base frequency without loss of lock. For example, to change a VCO frequency by 40% without losing lock, change the frequency by 20%, then change it again by 16.7%.

Peripheral Clock Group

The peripheral clock group consists of a PLL, dividers, and clock gating. The clocks in the peripheral clock group are derived from the peripheral PLL. The peripheral PLL can be programmed to be sourced from the `HPS_CLK1` pin, the `HPS_CLK2` pin, or the `f2h_periph_ref_clk` clock provided by the FPGA fabric.

The FPGA fabric must be configured with an image that provides the `f2h_periph_ref_clk` before selecting it as the clock source. If the FPGA must be reconfigured and `f2h_periph_ref_clk` is being used by modules in the HPS, an alternate clock source must be selected prior to reconfiguring the FPGA.

Clocks that always use the peripheral PLL output clocks as the clocks source are:

- `emac0_clk`
- `emac1_clk`
- `usb_mp_clk`
- `spi_m_clk`
-
-
- `gpio_db_clk`
- `h2f_user1_clk`

In addition, clocks that may use the peripheral PLL output clocks as the clock source are:

- `sdmmc_clk`
- `nand_clk`
- `qspi_clk`
- `l4_mp_clk`
- `l4_sp_clk`

The counter outputs from the main PLL can have their frequency further divided by external dividers. Transitions to a different divide value occur on the fastest output clock, one clock cycle prior to the slowest clock's rising edge. For example, the clock transitions on cycle 15 of the divide-by-16 divider for the main C2 output and cycle 3 of the divide-by-4 divider for the C1 output.

Table 2-6: Peripheral PLL Output Assignments

PLL	Output Counter	Clock Name	Frequency	Phase Shift Control
Peripheral	C0	`emac0_base_clk`	Up to 250 MHz	No
	C1	`emac1_base_clk`	Up to 250 MHz	No
	C2	`periph_qspi_base_clk`	Up to 432 MHz	No
	C3	`periph_nand_sdmmc_base_clk`	Up to 250 MHz for the NAND flash controller and up to 200 MHz for the SD/MMC controller	No
	C4	`periph_base_base_clk`	Up to 240 MHz for the SPI masters and up to 200 MHz for the scan manager	No
	C5	`h2f_user1_base_clk`	`osc1_clk` to 100 MHz	No

The following figure shows programmable post-PLL dividers and clock gating for the peripheral clock group. Clock gate blocks in the diagram indicate clocks that may be gated off under software control. Software is expected to gate these clocks off prior to changing any PLL or divider settings that might create incorrect behavior on these clocks.

Figure 2-4: Peripheral Clock Group Divide and Gating

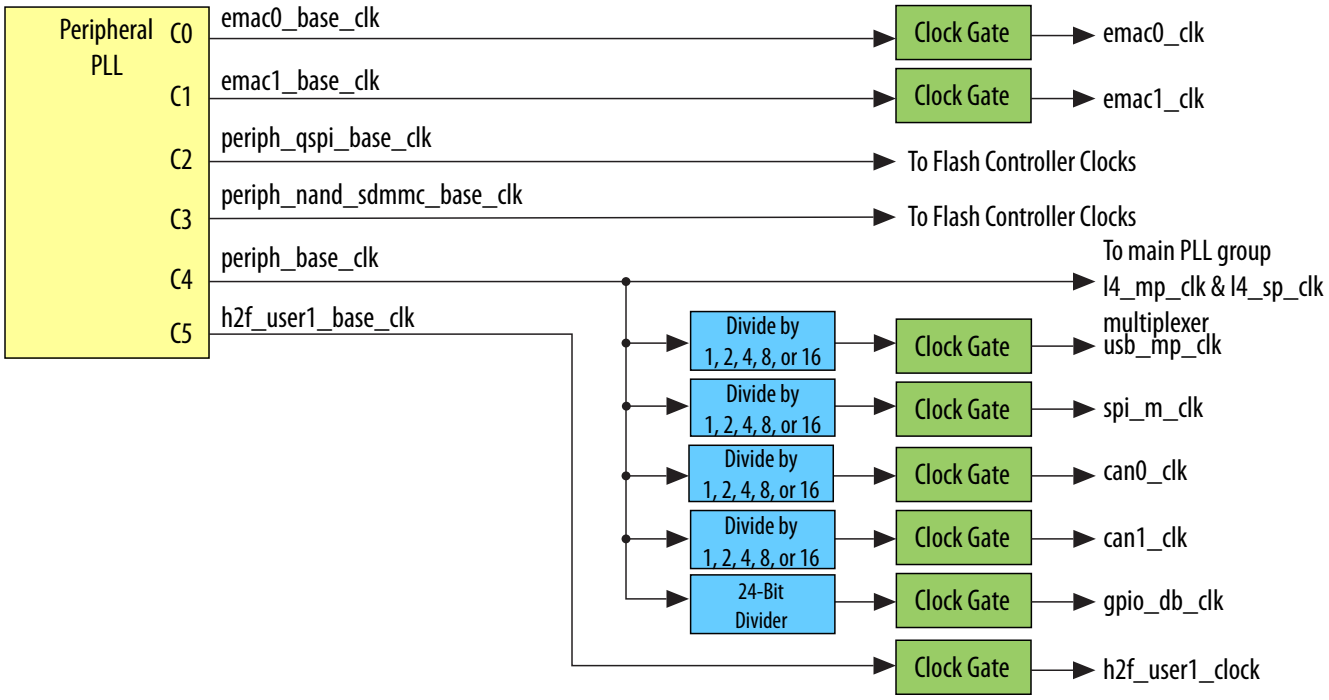


Table 2-7: Peripheral Clock Group Clocks

System Clock Name	Frequency	Divided From	Constraints and Notes
`usb_mp_clk`	Up to 200 MHz	Peripheral PLL C4	Clock for USB
`spi_m_clk`	Up to 240 MHz for the SPI masters and up to 200 MHz for the scan manager	Peripheral PLL C4	Clock for L4 SPI master bus and scan manager
`emac0_clk`	Up to 250 MHz	Peripheral PLL C0	EMAC0 clock. The 250 MHz clock is divided internally by the EMAC into the typical 125/25/2.5 MHz speeds for 1000/100/ 10 Mbps operation.

System Clock Name	Frequency	Divided From	Constraints and Notes
emac1_clk	Up to 250 MHz	Peripheral PLL C1	EMAC1 clock The 250 MHz clock is divided internally by the EMAC into the typical 125/25/2.5 MHz speeds for 1000/100/ 10 Mbps operation.
l4_mp_clk	Up to 100 MHz	Main PLL C1 or peripheral PLL C4	Clock for L4 master peripheral bus
l4_sp_clk	Up to 100 MHz	Main PLL C1 or peripheral PLL C4	Clock for L4 slave peripheral bus
gpio_db_clk	Up to 1 MHz	Peripheral PLL C4	Used to debounce GPIO0, GPIO1, and GPIO2
h2f_user1_clock	Peripheral PLL C5	Peripheral PLL C5	Auxiliary user clock to the FPGA fabric

Flash Controller Clocks

Flash memory peripherals can be driven by the main PLL, the peripheral PLL, or from clocks provided by the FPGA fabric.

Figure 2-5: Flash Peripheral Clock Divide and Gating

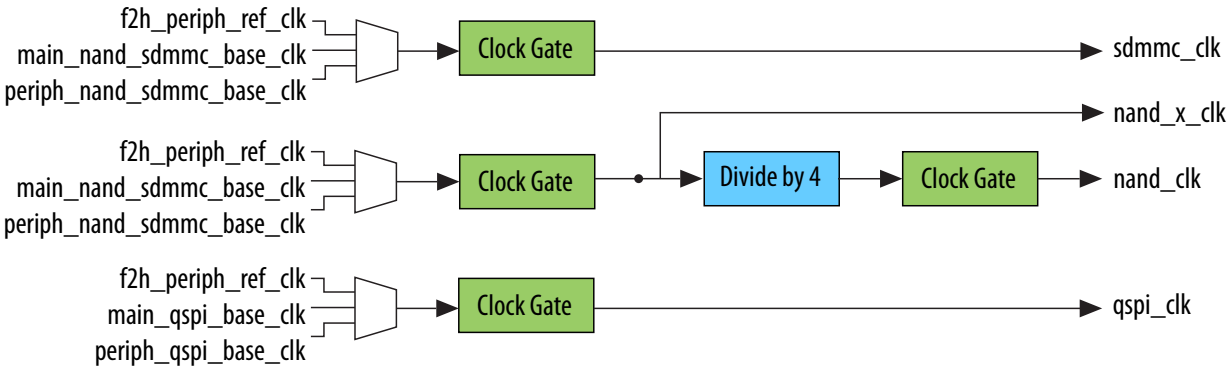

Table 2-8: Flash Controller Clocks

System Clock Name	Frequency	Divided From	Constraints and Notes
qspi_clk	Up to 432 MHz	Peripheral PLL C2, main PLL C3, or f2h_periph_ref_clk	Clock for quad SPI, typically 108 and 80 MHz
nand_x_clk	Up to 250 MHz	Peripheral PLL C3, main PLL C4, or f2h_periph_ref_clk	NAND flash controller master and slave clock
nand_clk	nand_x_clk/4	Peripheral PLL C3, main PLL C4, or f2h_periph_ref_clk	Main clock for NAND flash controller, sets base frequency for NAND transactions
sdmmc_clk	Up to 200 MHz	Peripheral PLL C3, main PLL C4, or f2h_periph_ref_clk	• Less than or equal to memory maximum operating frequency • 45% to 55% duty cycle • Typical frequencies are 26 and 52 MHz • SD/MMC has a subclock tree divided down from this clock

SDRAM Clock Group

The SDRAM clock group consists of a PLL and clock gating. The clocks in the SDRAM clock group are derived from the SDRAM PLL. The SDRAM PLL can be programmed to be sourced from the HPS_CLK1 pin, the HPS_CLK2 pin, or the f2h_sdram_ref_clk clock provided by the FPGA fabric.

The FPGA fabric must be configured with an image that provides the f2h_sdram_ref_clk before selecting it as the clock source. If the FPGA must be reconfigured and the f2h_sdram_ref_clk is the clock source for the SDRAM clock group, an alternate clock source must be selected prior to reconfiguring the FPGA.

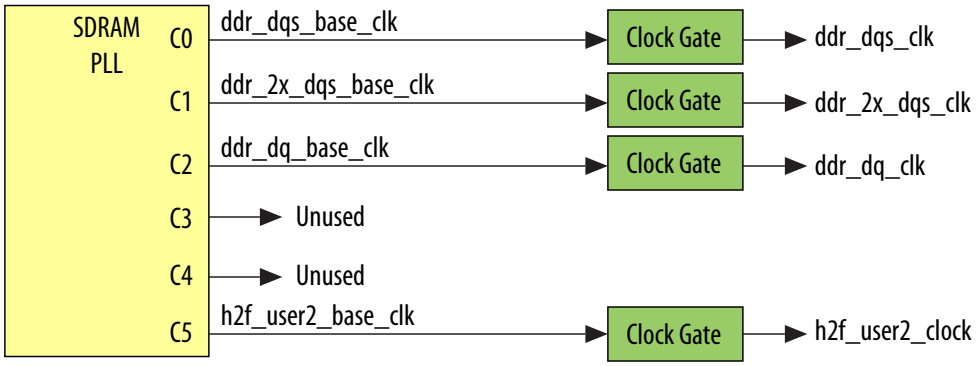
The counter outputs from the SDRAM PLL can be gated off directly under software control. The divider values for each clock are set by registers in the clock manager.

Table 2-9: SDRAM PLL Output Assignments

PLL	Output Counter	Clock Name	Frequency	Phase Shift Control
SDRAM	C0	ddr_dqs_base_clk	Varies (7)	Yes
	C1	ddr_2x_dqs_base_clk	ddr_dqs_base_clk x 2	Yes
	C2	ddr_dq_base_clk	ddr_dqs_base_clk	Yes
	C5	h2f_user2_base_clk	osc1_clk to varies(7)	Yes

The following figure shows clock gating for SDRAM PLL clock group. Clock gate blocks in the diagram indicate clocks which may be gated off under software control. Software is expected to gate these clocks off prior to changing any PLL or divider settings that might create incorrect behavior on these clocks.

Figure 2-6: SDRAM Clock Group Divide and Gating



The SDRAM PLL output clocks can be phase shifted in real time in increments of 1/8 the VCO frequency. Maximum number of phase shift increments is 4096.

Table 2-10: SDRAM Clock Group Clocks

Name	Frequency	Constraints and Notes
ddr_dqs_clk	SDRAM PLL C0	Clock for MPFE, single-port controller, CSR access, and PHY

(7) The maximum frequency depends on the speed grade of the device.

Name	Frequency	Constraints and Notes
ddr_2x_dqs_clk	SDRAM PLL C1	Clock for PHY
ddr_dq_clk	SDRAM PLL C2	Clock for PHY
h2f_user2_clock	SDRAM PLL C5	Auxiliary user clock to the FPGA fabric

Resets

Cold Reset

Cold reset places the hardware-managed clocks into safe mode, the software-managed clocks into their default state, and asynchronously resets all registers in the clock manager.

Related Information

Safe Mode on page 2-16

Warm Reset

Registers in the clock manager control how the clock manager responds to warm reset. Typically, software places the clock manager into a safe state in order to generate a known set of clocks for the ROM code to boot the system. The behavior of the system on warm reset as a whole, including how the FPGA fabric, boot code, and debug systems are configured to behave, must be carefully considered when choosing how the clock manager responds to warm reset.

The reset manager can request that the clock manager go into safe mode as part of the reset manager's warm reset sequence. Before asserting safe mode to the clock manager, the reset manager ensures that the reset signal is asserted to all modules that receive warm reset.

Related Information

Reset Manager on page 3-1
For more information, refer to "Reset Sequencing" in the *Reset Manager* chapter.

Safe Mode

Safe mode is enabled in the HPS by the assertion of a safe mode request from the reset manager or by a cold reset. Assertion of the safe mode request from the reset manager sets the safe mode bit in the clock manager control register. No other control register bits are affected by the safe mode request from the reset manager.

When safe mode is enabled, the main PLL hardware-managed clocks (C0-C2) are bypassed to `osc1_clk` clock and are directly generated from `osc1_clk`. While in safe mode, clock manager register settings, which control clock behavior, are not changed. However, the hardware bypasses these settings and uses safe, default settings.

The hardware-managed clocks are forced to their safe mode values such that the following conditions occur:

- The hardware-managed clocks are bypassed to `osc1_clk`, including counters in the main PLL.
- Programmable dividers select the reset default values.
- The flash controller clocks multiplexer selects the output from the peripheral PLL.
- All clocks are enabled.

A write by software is the only way to clear the safe mode bit (`safemode`) of the `ctrl` register.

Note: Before coming out of safe mode, all registers and clocks must be configured correctly. It is possible to program the clock manager in such a way that only a cold reset can return the clocks to a functioning state. Altera strongly recommends using Altera-provided libraries to configure and control HPS clocks.

Interrupts

The clock manager provides one interrupt output which is enabled using the interrupt enable register (`intren`). The interrupt is the OR of the bits in the interrupt status register (`inter`) that indicate lock and loss of lock for each of the three PLLs.

Clock Usage By Module

The following table lists every clock input generated by the clock manager to all modules in the HPS. System clock names are global for the entire HPS and system clocks with the same name are phase-aligned at all endpoints.

Table 2-11: Clock Usage By Module

Module Name	System Clock Name	Use
MPU subsystem	`mpu_clk`	Main clock for the MPU subsystem
	`mpu_periph_clk`	Peripherals inside the MPU subsystem
	`dbg_at_clk`	Trace bus
	`dbg_clk`	Debug
	`mpu_l2_ram_clk`	L2 cache and Accelerator Coherency Port (ACP) ID mapper
	`l4_mp_clk`	ACP ID mapper control slave

Module Name	System Clock Name	Use
Interconnect	l3_main_clk	L3 main switch
	dbg_at_clk	System Trace Macrocell (STM) slave and Embedded Trace Router (ETR) master connections
	dbg_clk	DAP master connection
	l3_mp_clk	L3 master peripheral switch
	l4_mp_clk	L4 MP bus, Secure Digital (SD) / MultiMediaCard (MMC) master, and EMAC masters
	usb_mp_clk	USB masters and slaves
	nand_x_clk	NAND master
	cfg_clk	FPGA manager configuration data slave
	l3_sp_clk	L3 slave peripheral switch
	l3_main_clk	L4 SPIS bus master
	mpu_l2_ram_clk	ACP ID mapper slave and L2 master connections
	osc1_clk	L4 OSC1 bus master
	spi_m_clk	L4 SPIM bus master
	l4_sp_clk	L4 SP bus master
	l4_mp_clk	Quad SPI bus slave
Boot ROM	l3_main_clk	Boot ROM
On-chip RAM	l3_main_clk	On-chip RAM

Module Name	System Clock Name	Use
DMA controller	l4_main_clk	DMA
	dbg_at_clk	Synchronous to the STM module
	l4_mp_clk	Synchronous to the quad SPI flash
FPGA manager	cfg_clk	Control block (CB) data interface and configuration data slave
	l4_mp_clk	Control slave
HPS-to-FPGA bridge	l3_main_clk	Data slave
	l4_mp_clk	Global programmer's view (GPV) slave
FPGA-to-HPS bridge	l3_main_clk	Data master
	l4_mp_clk	GPV slave
Lightweight HPS-to-FPGA bridge	l4_mp_clk	GPV masters and the data and GPV slave
Quad SPI flash controller	l4_mp_clk	Control slave
	qspi_clk	Reference for serialization
SD/MMC controller	l4_mp_clk	Master and slave
	sdmmc_clk	SD/MMC internal logic
EMAC 0	l4_mp_clk	Master
	emac0_clk	EMAC 0 internal logic
	osc1_clk	IEEE 1588 timestamp

Module Name	System Clock Name	Use
EMAC 1	l4_mp_clk	Master
	emac1_clk	EMAC 1 internal logic
	osc1_clk	IEEE 1588 timestamp
USB 0	usb_mp_clk	Master and Slave
USB 1	usb_mp_clk	Master and Slave
NAND flash controller	nand_x_clk	NAND high-speed master and slave
	nand_clk	NAND flash
OSC1 timer 0	osc1_clk	OSC1 timer 0
OSC1 timer 1	osc1_clk	OSC1 timer 1
SP timer 0	l4_sp_clk	SP timer 0
SP timer 1	l4_sp_clk	SP timer 1
I^2C controller 0	l4_sp_clk	I^2C 0
I^2C controller 1	l4_sp_clk	I^2C 1
I^2C controller 2	l4_sp_clk	I^2C 2
I^2C controller 3	l4_sp_clk	I^2C 3
UART controller 0	l4_sp_clk	UART 0
UART controller 1	l4_sp_clk	UART 1

Module Name	System Clock Name	Use
GPIO interface 0	l4_mp_clk	Slave
	gpio_db_clk	Debounce
GPIO interface 1	l4_mp_clk	Slave
	gpio_db_clk	Debounce
GPIO interface 2	l4_mp_clk	Slave
	gpio_db_clk	Debounce
System manager	osc1_clk	System manager
SDRAM subsystem	l4_sp_clk	Control slave
	ddr_dq_clk	Off-chip data
	ddr_dqs_clk	MPFE, single-port controller, CSRs, and PHY
	ddr_2x_dqs_clk	Off-chip strobe data
	mpu_l2_ram_clk	Slave connected to MPU subsystem L2 cache
	l3_main_clk	Slave connected to L3 interconnect
L4 watchdog timer 0	osc1_clk	L4 watchdog timer 0
L4 watchdog timer 1	osc1_clk	L4 watchdog timer 1
SPI master controller 0	spi_m_clk	SPI master 0
SPI master controller 1	spi_m_clk	SPI master 1
SPI slave controller 0	l4_main_clk	SPI slave 0

Module Name	System Clock Name	Use
SPI slave controller 1	l4_main_clk	SPI slave 1
Debug subsystem	l4_mp_clk	System bus
	dbg_clk	Debug
	dbg_at_clk	Trace bus
	dbg_trace_clk	Trace port
Reset manager	osc1_clk	Reset manager
	l4_sp_clk	Slave
Scan manager	spi_m_clk	Scan manager
Timestamp generator	dbg_timer_clk	Timestamp generator

Clock Manager Address Map and Register Definitions

The address map and register definitions for the HPS-FPGA bridge consist of the following regions:

- Clock Manager Module

stat Fields

Bit	Name	Description	Access	Reset
0	busy	This read only bit indicates that the Hardware Managed clock's state machine is active. If the state machine is active, then the clocks are in transition. Software should poll this bit after changing the source of internal clocks when writing to the BYPASS, CTRL or DBCTRL registers. Immediately following writes to any of these registers, SW should wait until this bit is IDLE before proceeding with any other register writes in the Clock Manager. The reset value of this bit is applied on a cold reset; warm reset has no affect on this bit. **Value** **Description** 0x0 Clocks stable 0x1 Clocks in transition	RO	0x0

Main PLL Group Register Descriptions

Contains registers with settings for the Main PLL.

Offset: 0x40

vco on page 2-32
Contains settings that control the Main PLL VCO. The VCO output frequency is the input frequency multiplied by the numerator (M+1) and divided by the denominator (N+1). The VCO input clock source is always eosc1_clk. Fields are only reset by a cold reset.

misc on page 2-34
Contains VCO control signals and other PLL control signals need to be controllable through register. Fields are only reset by a cold reset.

mpuclk on page 2-35
Contains settings that control clock mpu_clk generated from the C0 output of the Main PLL. Only reset by a cold reset.

mainclk on page 2-35
Contains settings that control clock main_clk generated from the C1 output of the Main PLL. Only reset by a cold reset.

dbgatclk on page 2-36
Contains settings that control clock dbg_base_clk generated from the C2 output of the Main PLL. Only reset by a cold reset.

mainqspiclk on page 2-36
Contains settings that control clock main_qspi_clk generated from the C3 output of the Main PLL. Only reset by a cold reset.

mainnandsdmmcclk on page 2-37
Contains settings that control clock main_nand_sdmmc_clk generated from the C4 output of the Main PLL. Only reset by a cold reset.

cfgs2fuser0clk on page 2-38
Contains settings that control clock cfg_s2f_user0_clk generated from the C5 output of the Main PLL. Qsys and user documenation refer to cfg_s2f_user0_clk as cfg_h2f_user0_clk. Only reset by a cold reset.

en on page 2-38
Contains fields that control clock enables for clocks derived from the Main PLL. 1: The clock is enabled. 0: The clock is disabled. Fields are only reset by a cold reset.

maindiv on page 2-39
Contains fields that control clock dividers for main clocks derived from the Main PLL Fields are only reset by a cold reset.

dbgdiv on page 2-41
Contains fields that control clock dividers for debug clocks derived from the Main PLL Fields are only reset by a cold reset.

tracediv on page 2-42
Contains a field that controls the clock divider for the debug trace clock derived from the Main PLL Only reset by a cold reset.

l4src on page 2-42
Contains fields that select the clock source for L4 MP and SP APB interconnect Fields are only reset by a cold reset.

stat on page 2-43
Contains Output Clock Counter Reset acknowledge status.

vco

Contains settings that control the Main PLL VCO. The VCO output frequency is the input frequency multiplied by the numerator (M+1) and divided by the denominator (N+1). The VCO input clock source is always eosc1_clk. Fields are only reset by a cold reset.

numer RW 0x1													pwrdn RW 0x1	en RW 0x0	bgpwrdn RW 0x1

vco Fields

Bit	Name	Description	Access	Reset
31	regextsel	If set to '1', the external regulator is selected for the PLL. If set to '0', the internal regulator is slected. It is strongly recommended to select the external regulator while the PLL is not enabled (in reset), and then disable the external regulater once the PLL becomes enabled. Software should simulateously update the 'Enable' bit and the 'External Regulator Input Select' in the same write access to the VCO register. When the 'Enable' bit is clear, the 'External Regulator Input Select' should be set, and vice versa. The reset value of this bit is applied on a cold reset; warm reset has no affect on this bit.	RW	0x1
30:25	outreset	Resets the individual PLL output counter. For software to change the PLL output counter without producing glitches on the respective clock, SW must set the VCO register respective Output Counter Reset bit. Software then polls the respective Output Counter Reset Acknowledge bit in the Output Counter Reset Ack Status Register. Software then writes the appropriate counter register, and then clears the respective VCO register Output Counter Reset bit. LSB 'outreset[0]' corresponds to PLL output clock C0, etc. If set to '1', reset output divider, no clock output from counter. If set to '0', counter is not reset. The reset value of this bit is applied on a cold reset; warm reset has no affect on this bit.	RW	0x0
24	outresetall	Before releasing Bypass, All Output Counter Reset must be set and cleared by software for correct clock operation. If '1', Reset phase multiplexer and all output counter state. So that after the assertion all the clocks output are start from rising edge align. If '0', phase multiplexer and output counter state not reset and no change to the phase of the clock outputs.	RW	0x0

Bit	Name	Description	Access	Reset
21:16	denom	Denominator in VCO output frequency equation. For incremental frequency change, if the new value lead to less than 20% of the frequency change, this value can be changed without resetting the PLL. The Numerator and Denominator can not be changed at the same time for incremental frequency changed.	RW	0x1
15:3	numer	Numerator in VCO output frequency equation. Note that the valid range for this field is 0x000 to 0xFFF (0 to 4095). The most significant bit of this field is reserved and should not be used. For incremental frequency change, if the new value lead to less than 20% of the frequency change, this value can be changed without resetting the PLL. The Numerator and Denominator can not be changed at the same time for incremental frequency changed.	RW	0x1
2	pwrdn	If '1', power down analog circuitry. If '0', analog circuitry not powered down.	RW	0x1
1	en	If '1', VCO is enabled. If '0', VCO is in reset.	RW	0x0
0	bgpwrdn	If '1', powers down bandgap. If '0', bandgap is not power down.	RW	0x1

misc

Contains VCO control signals and other PLL control signals need to be controllable through register. Fields are only reset by a cold reset.

5:0	outresetack	These read only bits per PLL output indicate that the PLL has received the Output Reset Counter request and has gracefully stopped the respective PLL output clock. For software to change the PLL output counter without producing glitches on the respective clock, SW must set the VCO register respective Output Counter Reset bit. Software then polls the respective Output Counter Reset Acknowledge bit in the Output Counter Reset Ack Status Register. Software then writes the appropriate counter register, and then clears the respective VCO register Output Counter Reset bit. The reset value of this bit is applied on a cold reset; warm reset has no affect on this bit. **Value** **Description** 0x0 Idle 0x1 Output Counter Acknowledge received.	RO	0x0

Peripheral PLL Group Register Descriptions

Contains registers with settings for the Peripheral PLL.

Offset: 0x80

vco on page 2-45
Contains settings that control the Peripheral PLL VCO. The VCO output frequency is the input frequency multiplied by the numerator (M+1) and divided by the denominator (N+1). Fields are only reset by a cold reset.

misc on page 2-47
Contains VCO control signals and other PLL control signals need to be controllable through register. Fields are only reset by a cold reset.

emac0clk on page 2-48
Contains settings that control clock emac0_clk generated from the C0 output of the Peripheral PLL. Only reset by a cold reset.

emac1clk on page 2-48
Contains settings that control clock emac1_clk generated from the C1 output of the Peripheral PLL. Only reset by a cold reset.

perqspiclk on page 2-49
Contains settings that control clock periph_qspi_clk generated from the C2 output of the Peripheral PLL. Only reset by a cold reset.

pernandsdmmcclk on page 2-49
Contains settings that control clock periph_nand_sdmmc_clk generated from the C3 output of the Peripheral PLL. Only reset by a cold reset.

perbaseclk on page 2-50
Contains settings that control clock periph_base_clk generated from the C4 output of the Peripheral PLL. Only reset by a cold reset.

s2fuser1clk on page 2-50
Contains settings that control clock s2f_user1_clk generated from the C5 output of the Peripheral PLL. Qsys and user documenation refer to s2f_user1_clk as h2f_user1_clk. Only reset by a cold reset.

en on page 2-51
Contains fields that control clock enables for clocks derived from the Peripheral PLL 1: The clock is enabled. 0: The clock is disabled. Fields are only reset by a cold reset.

div on page 2-52
Contains fields that control clock dividers for clocks derived from the Peripheral PLL Fields are only reset by a cold reset.

gpiodiv on page 2-54
Contains a field that controls the clock divider for the GPIO De-bounce clock. Only reset by a cold reset.

src on page 2-55
Contains fields that select the source clocks for the flash controllers. Fields are only reset by a cold reset.

stat on page 2-56
Contains Output Clock Counter Reset acknowledge status.

vco

Contains settings that control the Peripheral PLL VCO. The VCO output frequency is the input frequency multiplied by the numerator (M+1) and divided by the denominator (N+1). Fields are only reset by a cold reset.

vco Fields

Bit	Name	Description	Access	Reset
31	regextsel	If set to '1', the external regulator is selected for the PLL. If set to '0', the internal regulator is slected. It is strongly recommended to select the external regulator while the PLL is not enabled (in reset), and then disable the external regulater once the PLL becomes enabled. Software should simulateously update the 'Enable' bit and the 'External Regulator Input Select' in the same write access to the VCO register. When the 'Enable' bit is clear, the 'External Regulator Input Select' should be set, and vice versa. The reset value of this bit is applied on a cold reset; warm reset has no affect on this bit.	RW	0x1
30:25	outreset	Resets the individual PLL output counter. For software to change the PLL output counter without producing glitches on the respective clock, SW must set the VCO register respective Output Counter Reset bit. Software then polls the respective Output Counter Reset Acknowledge bit in the Output Counter Reset Ack Status Register. Software then writes the appropriate counter register, and then clears the respective VCO register Output Counter Reset bit. LSB 'outreset[0]' corresponds to PLL output clock C0, etc. If set to '1', reset output divider, no clock output from counter. If set to '0', counter is not reset. The reset value of this bit is applied on a cold reset; warm reset has no affect on this bit.	RW	0x0
24	outresetall	Before releasing Bypass, All Output Counter Reset must be set and cleared by software for correct clock operation. If '1', Reset phase multiplexer and all output counter state. So that after the assertion all the clocks output are start from rising edge align. If '0', phase multiplexer and output counter state not reset and no change to the phase of the clock outputs.	RW	0x0
23:22	psrc	Controls the VCO input clock source. Qsys and user documenation refer to f2s_periph_ref_clk as f2h_ periph_ref_clk. **Value** — **Description** 0x0 — eosc1_clk 0x1 — eosc2_clk 0x2 — f2s_periph_ref_clk	RW	0x0

Bit	Name	Description	Access	Reset
21:16	denom	Denominator in VCO output frequency equation. For incremental frequency change, if the new value lead to less than 20% of the frequency change, this value can be changed without resetting the PLL. The Numerator and Denominator can not be changed at the same time for incremental frequency changed.	RW	0x1
15:3	numer	Numerator in VCO output frequency equation. For incremental frequency change, if the new value lead to less than 20% of the frequency change, this value can be changed without resetting the PLL. The Numerator and Denominator can not be changed at the same time for incremental frequency changed.	RW	0x1
2	pwrdn	If '1', power down analog circuitry. If '0', analog circuitry not powered down.	RW	0x1
1	en	If '1', VCO is enabled. If '0', VCO is in reset.	RW	0x0
0	bgpwrdn	If '1', powers down bandgap. If '0', bandgap is not power down.	RW	0x1

misc

Contains VCO control signals and other PLL control signals need to be controllable through register. Fields are only reset by a cold reset.

Reset Manager 3

2014.12.15

av_5v4 Subscribe Send Feedback

The reset manager generates module reset signals based on reset requests from the various sources in the HPS and FPGA fabric, and software writing to the module-reset control registers. The reset manager ensures that a reset request from the FPGA fabric can occur only after the FPGA portion of the system-on-a-chip (SoC) device is configured.

The HPS contains three reset domains. Each reset domain can be reset independently. Each register in the HPS that can be reset belongs to one particular reset domain.

Table 3-1: HPS Reset Domains

Domain Name	Domain Logic
TAP	JTAG test access port (TAP) controller, which is used by the debug access port (DAP).
Debug	All debug logic including most of the DAP, CoreSight™ components connected to the debug peripheral bus, trace, the microprocessor unit (MPU) subsystem, and the FPGA fabric.
System	All HPS logic except what is in the TAP and debug reset domains. Includes non-debug logic in the FPGA fabric connected to the HPS reset signals.

The HPS supports the following reset types:

- System cold reset
  - Used to ensure the HPS is placed in a default state sufficient for software to boot
  - Triggered by a power-on reset and other sources
  - Resets all HPS logic that can be reset
  - Affects all reset domains
- System warm reset
  - Occurs after HPS has already completed a cold reset
  - Used to recover system from a non-responsive condition
  - Resets a subset of the HPS state reset by a cold reset
  - Only affects the system reset domain, which allows debugging (including trace) to operate through the warm reset
- Debug reset
  - Used to recover debug logic from a non-responsive condition
  - Only affects the debug reset domain

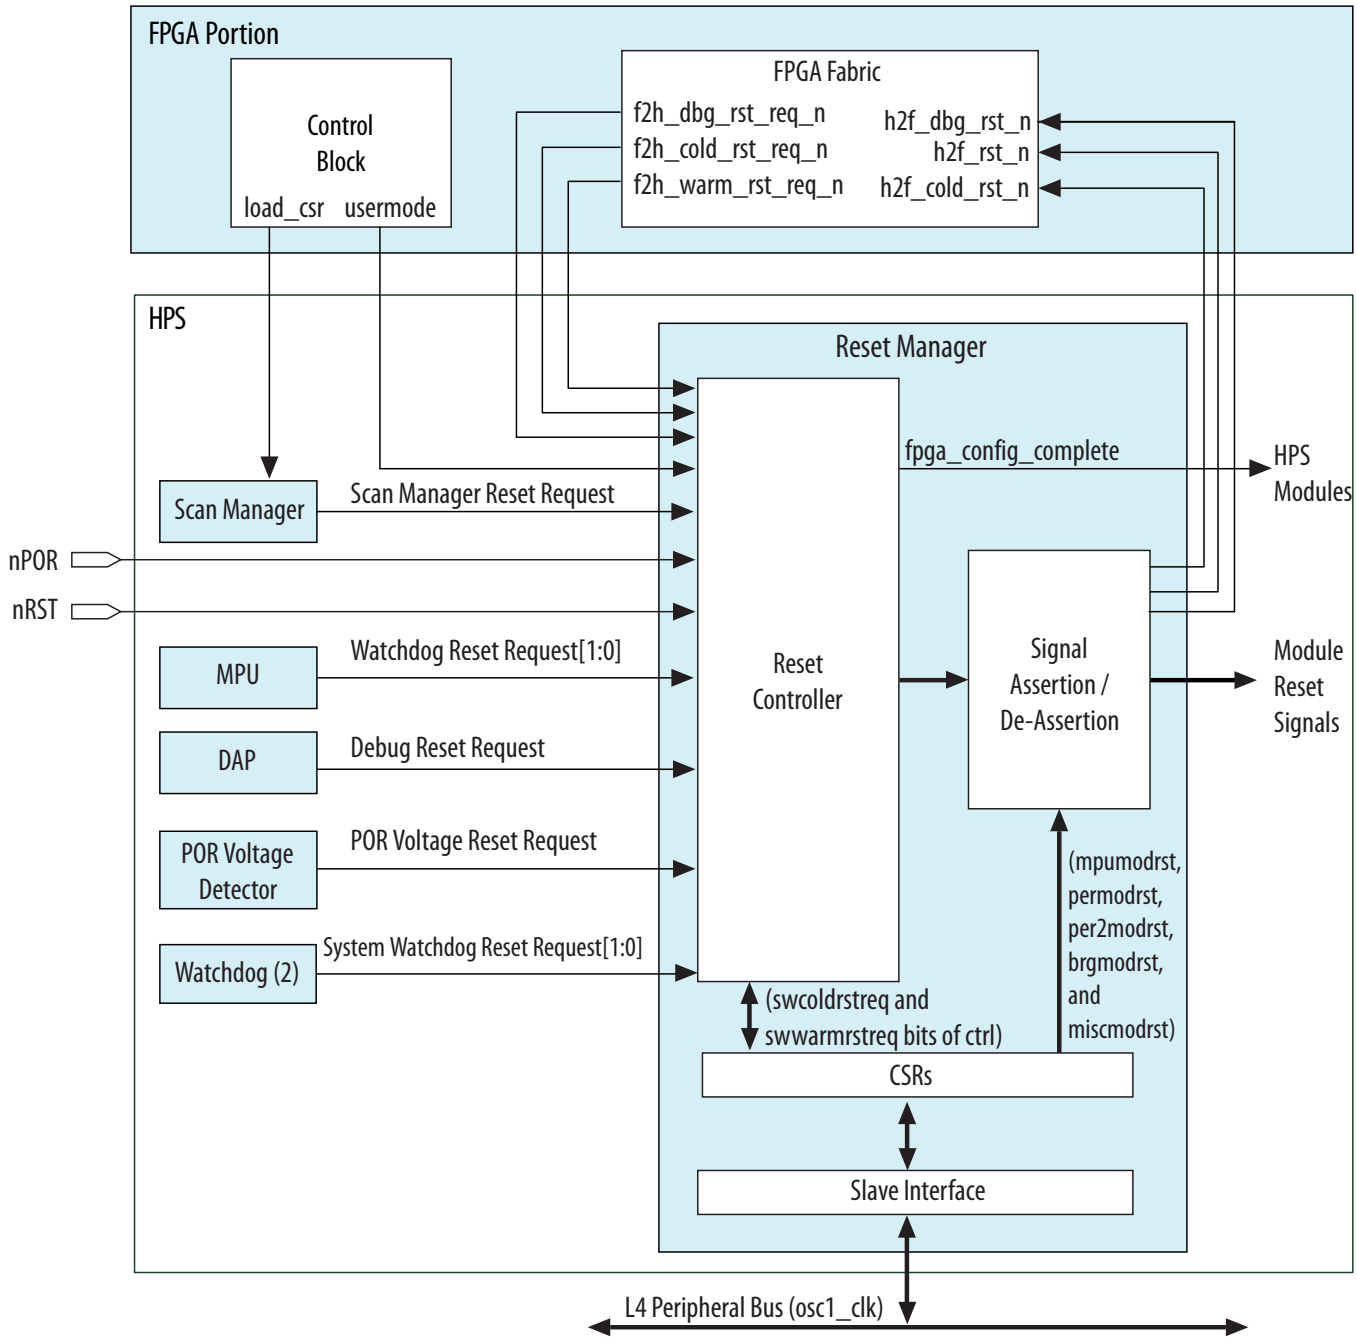
Reset Manager Block Diagram and System Integration

Figure 3-1: Reset Manager Block Diagram

The following figure shows a block diagram of the reset manager in the SoC device. For clarity, reset-related handshaking signals to other HPS modules and to the clock manager module are omitted.



HPS External Reset Sources

The following table lists the reset sources external to the HPS. All signals are synchronous to the `osc1_clk` clock. The reset signals from the HPS to the FPGA fabric must be synchronized to your user logic clock domain.

Table 3-2: HPS External Reset Sources

Source	Description
f2h_cold_rst_req_n	Cold reset request from FPGA fabric (active low)
f2h_warm_rst_req_n	Warm reset request from FPGA fabric (active low)
f2h_dbg_rst_req_n	Debug reset request from FPGA fabric (active low)
h2f_cold_rst_n	Cold-only reset to FPGA fabric (active low)
h2f_rst_n	Cold or warm reset to FPGA fabric (active low)
h2f_dbg_rst_n	Debug reset (dbg_rst_n) to FPGA fabric (active low)
load_csr	Cold-only reset from FPGA control block (CB) and scan manager
nPOR	Power-on reset pin (active low)
nRST	Warm reset pin (active low)

nRST and nPOR are powered by the HPS reset and clock input pins power supply ($V_{CCRSTCLK}$_HPS). For more information on $V_{CCRSTCLK}$_HPS, refer to the *Arria V Device Datasheet.*

Reset Controller

The reset controller performs the following functions:

- Accepts reset requests from the FPGA CB, FPGA fabric, modules in the HPS, and reset pins
- Generates an individual reset signal for each module instance for all modules in the HPS
- Provides reset handshaking signals to support system reset behavior

The reset controller generates module reset signals from external reset requests and internal reset requests. External reset requests originate from sources external to the reset manager. Internal reset requests originate from control registers in the reset manager.

The reset controller supports the following cold reset requests:

- Power-on reset (POR) voltage monitor
- Cold reset request pin (nPOR)
- FPGA fabric
- FPGA CB and scan manager
- Software cold reset request bit (swcoldrstreq) of the control register (ctrl)

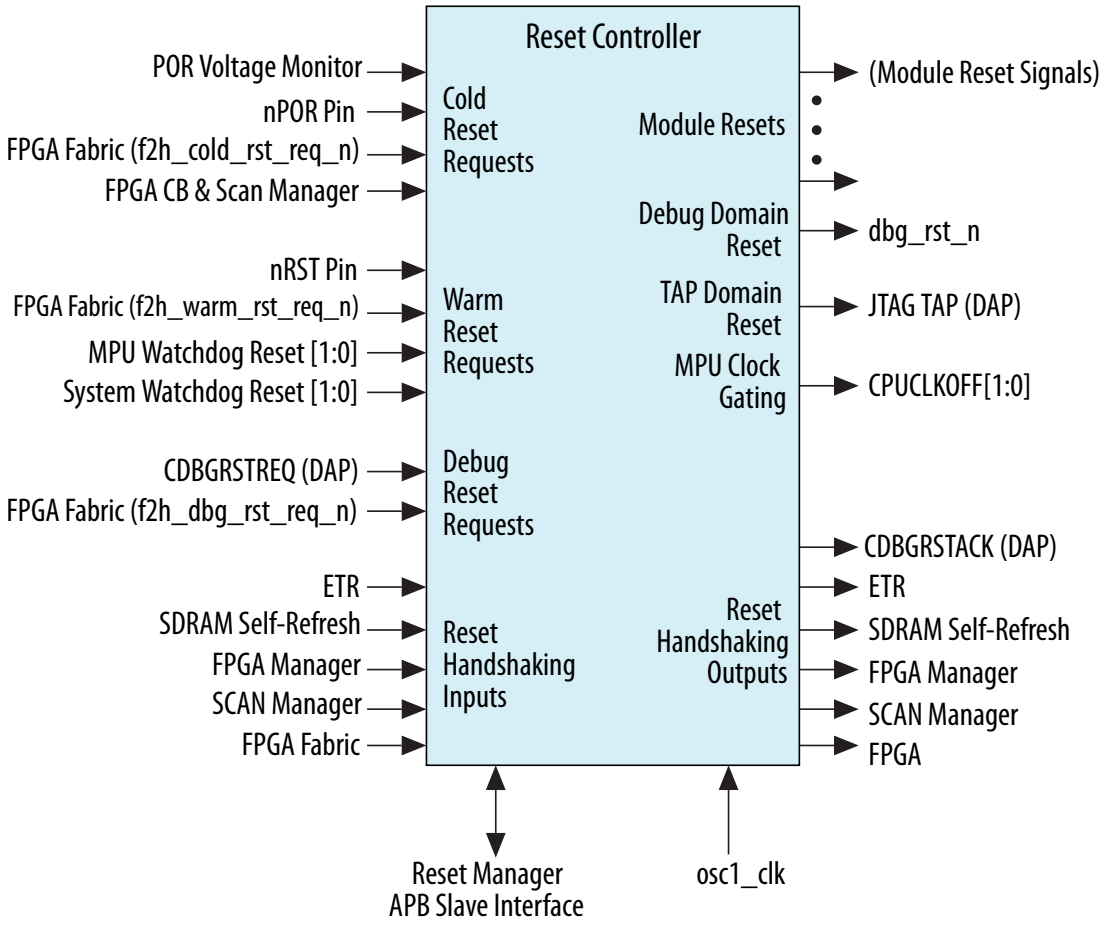
The reset controller supports the following warm reset requests:

- Warm reset request pin (nRST)
- FPGA fabric
- Software warm reset request bit (swwarmrstreq) of the ctrl register
- MPU watchdog reset requests for CPU0 and CPU1
- System watchdog timer 0 and 1 reset requests

The reset controller supports the following debug reset requests:

- CDBGRSTREQ from DAP
- FPGA fabric

Figure 3-2: Reset Controller Signals



Module Reset Signals

The following tables list the module reset signals. The module reset signals are organized in groups for the MPU, peripherals, bridges.

In the following tables, columns marked for Cold Reset, Warm Reset, and Debug Reset denote reset signals asserted by each type of reset. For example, writing a 1 to the swwarmrstreq bit in the ctrl register resets all the modules that have a checkmark in the Warm Reset column.

The column marked for Software Deassert denotes reset signals that are left asserted by the reset manager.

Table 3-3: MPU Group, Generated Module Resets

Modules Requiring Software Deassert

The reset manager leaves the reset signal asserted on certain modules even after the rest of the HPS has come out of reset. These modules are likely to require software configuration before they can safely be taken out of reset.

When a module that has been held in reset is ready to start running, software can deassert the reset signal by writing to the appropriate register, shown in the following table.

Table 3-9: Module Reset Signals and Registers

HPS Peripheral	Reset Register	Module Reset Signal	Reset Group

Slave Interface and Status Register

The reset manager slave interface is used to control and monitor the reset states.

The status register (stat) in the reset manager contains the status of the reset requester. The register contains a bit for each monitored reset request. The stat register captures all reset requests that have occurred. Software is responsible for clearing the bits.

Functional Description of the Reset Manager

The reset manager generates reset signals to modules in the HPS and to the FPGA fabric. The following actions generate reset signals:

- Software writing a 1 to the swcoldrstreq or swwarmrstreq bits in the ctrl register. Writing either bit causes the reset controller to perform a reset sequence.
- Software writing to the mpumodrst, permodrst, per2modrst, brgmodrst, or miscmodrst module reset control registers.
- Asserting reset request signals triggers the reset controller. All external reset requests cause the reset controller to perform a reset sequence.

Multiple reset requests can be driven to the reset manager at the same time. Cold reset requests take priority over warm and debug reset requests. Higher priority reset requests preempt lower priority reset requests. There is no priority difference among reset requests within the same domain.

If a cold reset request is issued while another cold reset is already underway, the reset manager extends the reset period for all the module reset outputs until all cold reset requests are removed. If a cold reset request is issued while the reset manager is removing other modules out of the reset state, the reset manager returns those modules back to the reset state.

If a warm reset request is issued while another warm reset is already underway, the first warm reset completes before the second warm reset begins. If the second warm reset request is removed before the first warm reset completes, the warm first reset is extended to meet the timing requirements of the second warm reset request.

The nPOR pin can be used to extend the cold reset beyond what the POR voltage monitor automatically provides. The use of the nPOR pin is optional and can be tied high when it is not required.

For information regarding HPS power supply operating conditions, refer to the device datasheet.

Related Information

Arria V GX, GT, SX, and ST Device Datasheet
For information about the required duration of reset request signal assertion, refer to the Arria V Device Datasheet.

Reset Sequencing

The reset controller sequences resets without software assistance. Module reset signals are asserted asynchronously and synchronously. The reset manager deasserts the module reset signals synchronous to the osc1_clk clock. Module reset signals are deasserted in groups in a fixed sequence. All module reset signals in a group are deasserted at the same time.

The reset manager sends a safe mode request to the clock manager to put the clock manager in safe mode, which creates a fixed and known relationship between the osc1_clk clock and all other clocks generated by the clock manager.

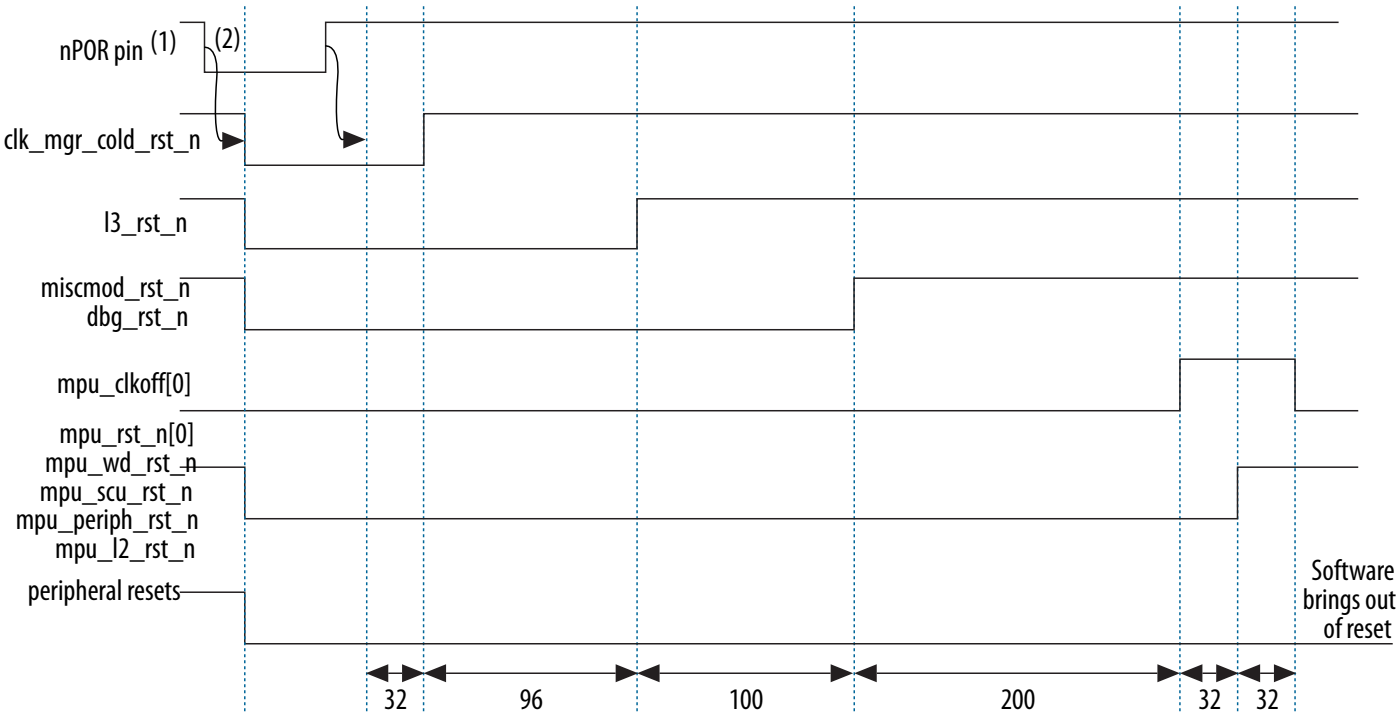
After the reset manager releases the MPU subsystem from reset, CPU1 is left in reset and CPU0 begins executing code from the reset vector address. Software is responsible for deasserting CPU1 and other resets, as shown in the MPU Group and Generated Module Resets table. Software deasserts resets by writing the mpumodrst, permodrst, per2modrst, brgmodrst, and miscmodrst module-reset control registers.

Software can also bypass the reset controller and generate reset signals directly through the module-reset control registers. In this case, software is responsible for asserting module reset signals, driving them for the appropriate duration, and deasserting them in the correct order. The clock manager is not typically in safe mode during this time, so software is responsible for knowing the relationship between the clocks generated by the clock manager. Software must not assert a module reset signal that would prevent software from deasserting the module reset signal. For example, software should not assert the module reset to the processor executing the software.

Table 3-10: Minimum Pulse Width

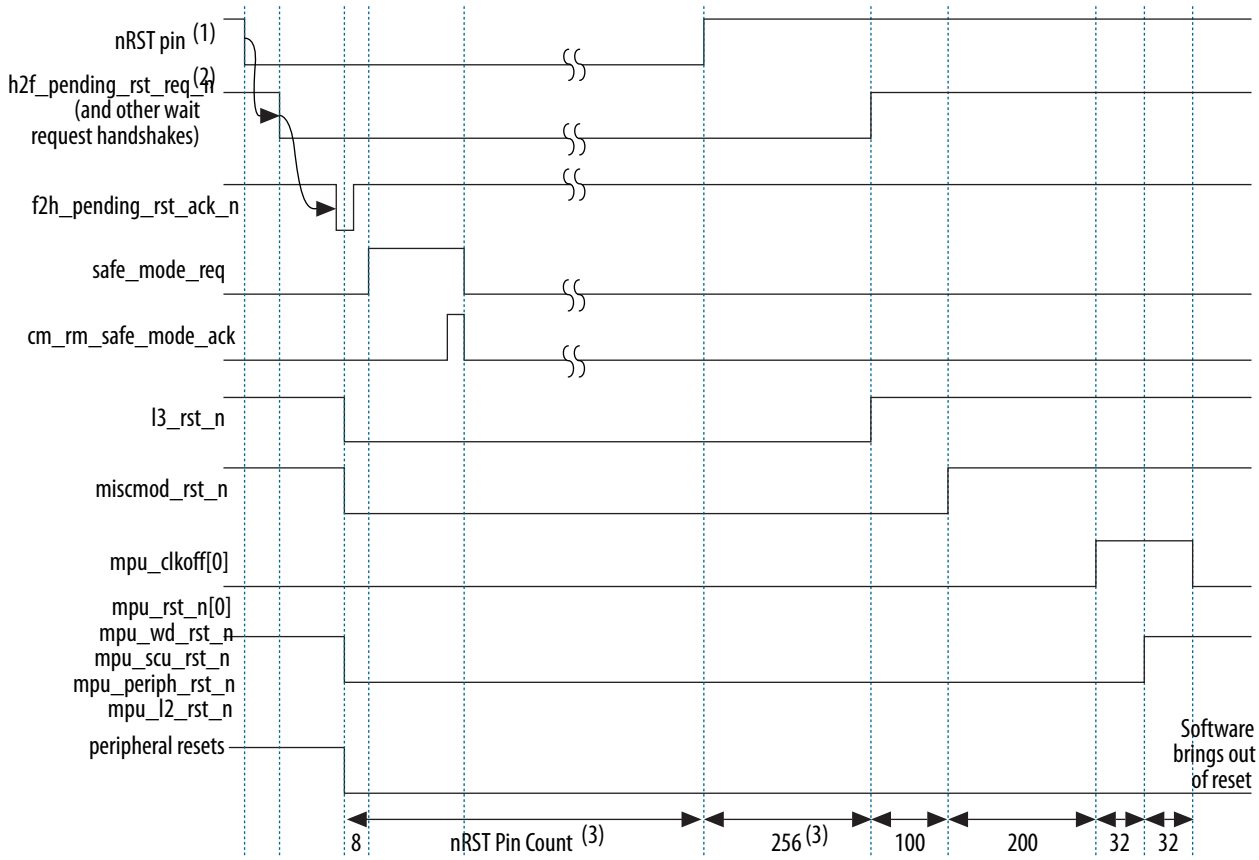
Reset Type	Value
Warm Reset	6 osc1_clk cycles
Cold Reset	6 osc1_clk cycles

Figure 3-3: Cold Reset Timing Diagram



(1) Cold reset can be initiated from several other sources: FPGA CB, FPGA fabric, modules in the HPS, and reset pins.
(2) This dependency applies to all the reset signals.

Figure 3-4: Warm Reset Timing Diagram



(1) Cold reset can be initiated from several other sources: FPGA CB, FPGA fabric, modules in the HPS, and reset pins.
(2) When the nRSTpin count is zero, the 256 cycle stretch count is skipped and the start of the deassertion sequence is determined by the safe mode acknowledge signal or the user releasing the warm reset button, whichever occurs later.

The cold and warm reset sequences consist of different reset assertion sequences and the same deassertion sequence. The following sections describe the sequences.

Note: Cold and warm reset affect only the `cpu0`, and by default cpu1 is held in reset until the software running in the `cpu0` releases it.

  For more information about safe mode, refer to the *Clock Manager* chapter.

Cold Reset Assertion Sequence

The following list describes the assertion steps for cold reset shown in the Cold Reset timing diagram:

1. Assert module resets
2. Wait for 32 cycles. Deassert clock manager cold reset.
3. Wait for 96 cycles (so clocks can stabilize).
4. Proceed to the "Cold and Warm Reset Deassertion Sequence" section using the following link.

Related Information

Cold and Warm Reset Deassertion Sequence on page 3-14

Warm Reset Assertion Sequence

The following list describes the assertion steps for warm reset shown in the Warm Reset Timing Diagram:

1. Optionally, handshake with the embedded trace router (ETR) and wait for acknowledge.
2. Optionally, handshake with the FPGA fabric and wait for acknowledge.
3. Optionally, handshake with the SDRAM controller, scan manager, and FPGA manager, and wait for acknowledges.
4. Assert module resets (except the MPU watchdog timer resets when the MPU watchdog timers are the only request sources).
5. Wait for 8 cycles and send a safe mode request to the clock manager.
6. Wait for the greater of the `nRST` pin count + 256 stretch count, or the warm reset counter, or the clock manager safe mode acknowledge, then deassert all handshakes except warm reset ETR handshake (which is deasserted by software).
7. Proceed to the "Cold and Warm Reset Deassertion Sequence" section using the following link.

Note: The nRST is a bidirectional signal that is driven out when a warm reset is generated in the chip.

Related Information

Cold and Warm Reset Deassertion Sequence on page 3-14

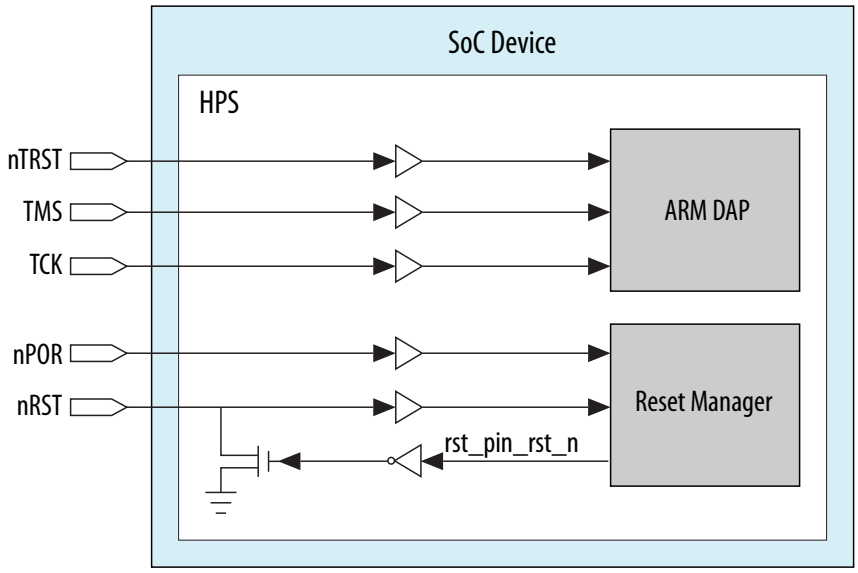
Cold and Warm Reset Deassertion Sequence

The following list describes the deassertion steps for both cold and warm reset shown in the Cold Reset Timing Diagram and Warm Reset Timing Diagram:

1. Deassert L3 reset.
2. Wait for 100 cycles. Deassert resets for miscellaneous-type and debug (cold only) modules.
3. Wait for 200 cycles. Assert `mpu_clkoff` for CPU0 and CPU1.
4. Wait for 32 cycles. Deassert resets for MPU modules.
5. Wait for 32 cycles. Deassert `mpu_clkoff` for CPU0 and CPU1.
6. Peripherals remain held in reset until software brings them out of reset.

Reset Pins

Figure 3-5: Reset Pins



The test reset (nTRST), test mode select (TMS), and test clock (TCK) pins are associated with the TAP reset domain and are used to reset the TAP controller in the DAP. These pins are not connected to the reset manager.

The nPOR and nRST pins are used to request cold and warm resets respectively. The nRST pin is an open drain output as well. Any cord or warm reset request causes the reset manager to drive the rst_pin_rst_n signal output low, which drives the nRST pin low. The amount of time the reset manager pulls nRST low is controlled by the nRST pin count field (nrstcnt) of the reset cycles count register (counts). This technique can be used to reset external devices (such as external memories) connected to the HPS.

Reset Effects

The following list describes how reset affects HPS logic:

- The TAP reset domain ignores warm reset.
- The debug reset domain ignores warm reset.
- System reset domain cold resets ignore warm reset.
- Each module defines reset behavior individually.

Altering Warm Reset System Response

Registers in the clock manager, system manager, and reset manager control how warm reset affects the HPS. You can control the impact of a warm reset on the clocks and I/O elements.

Altera strongly recommends using Altera-provided libraries to configure and control this functionality.

The default warm reset behavior takes all clocks and I/O elements through a cold reset response. As your software becomes more stable or for debug purposes, you can alter the system response to a warm reset. The following suggestions provide ways to alter the system response to a warm reset. None of the register bits that control these items are affected by warm reset.

- Boot from on-chip RAM—enables warm boot from on-chip RAM instead of the boot ROM. When enabled, the boot ROM code validates the RAM code and jumps to it, making no changes to clocks or any other system settings prior to executing user code from on-chip RAM.
- Disable safe mode on warm reset—allows software to transition through a warm reset without affecting the clocks. Because the boot ROM code indirectly configures the clock settings after warm reset, Altera recommends that safe mode should only be disabled when the HPS is not booting from a flash device.
- Disable safe mode on warm reset for the debug clocks—keeps the debug clocks from being affected by the assertion of safe mode request on a warm reset. This technique allows fast debug clocks, such as trace, to continue running through a warm reset. When enabled, the clock manager configures the debug clocks to their safe frequencies to respond to a safe mode request from the reset manager on a warm reset. Disable safe mode on warm reset for the debug clocks only when you are running the debug clocks off the main PLL VCO and you are certain the main PLL cannot be impacted by the event which caused the warm reset.
- Use the `osc1_clk` clock for debug control—keeps the debug base clock (main PLL C2 output) always bypassed to the `osc1_clk` external clock, independent of other clock manager settings. When implemented, disabling safe mode on warm reset for the debug clocks has no effect.

Related Information

Clock Manager on page 2-1
For more information about safe mode, refer to the *Clock Manager* chapter.

Reset Handshaking

The reset manager participates in several reset handshaking protocols to ensure other modules are safely reset.

Before issuing a warm reset, the reset manager performs a handshake with several modules to allow them to prepare for a warm reset. The handshake logic ensures the following conditions:

- Optionally the ETR master has no pending master transactions to the L3 interconnect
- Optionally preserve SDRAM contents during warm reset by issuing self-refresh mode request
- FPGA manager stops generating configuration clock
- Scan manager stops generating JTAG and I/O configuration clocks
- Warns the FPGA fabric of the forthcoming warm reset

Similarly, the handshake logic associated with ETR also occurs during the debug reset to ensure that the ETR master has no pending master transactions to the L3 interconnect before the debug reset is issued. This action ensures that when ETR undergoes a debug reset, the reset has no adverse effects on the system domain portion of the ETR.

Reset Manager Address Map and Register Definitions

The address map and register definitions for the HPS-FPGA bridge consist of the following regions:

- Reset Manager Module

stat

The STAT register contains bits that indicate the reset source or a timeout event. For reset sources, a field is 1 if its associated reset requester caused the reset. For timeout events, a field is 1 if its associated timeout occured as part of a hardware sequenced warm/debug reset. Software clears bits by writing them with a value of 1. Writes to bits with a value of 0 are ignored. After a cold reset is complete, all bits are reset to their reset value except for the bit(s) that indicate the source of the cold reset. If multiple cold reset requests overlap with each other, the source de-asserts the request last will be logged. The other reset request source(s) de-assert the request in the same cycle will also be logged, the rest of the fields are reset to default value of 0. After a warm reset is complete, the bit(s) that indicate the source of the warm reset

are set to 1. A warm reset doesn't clear any of the bits in the STAT register; these bits must be cleared by software writing the STAT register.

ctrl

The CTRL register is used by software to control reset behavior.It includes fields for software to initiate the cold and warm reset, enable hardware handshake with other modules before warm reset, and perform

software handshake. The software handshake sequence must match the hardware sequence. Software mustde-assert the handshake request after asserting warm reset and before de-assert the warm reset. Fields are only reset by a cold reset.

ctrl Fields

Bit	Name	Description	Access	Reset
23	etrstallwarmrst	If a warm reset occurs and ETRSTALLEN is 1, hardware sets this bit to 1 to indicate that the stall of the ETR AXI master is pending. Hardware leaves the ETR stalled until software clears this field by writing it with 1. Software must only clear this field when it is ready to have the ETR AXI master start making AXI requests to write trace data.	RW	0x0
22	etrstallack	This is the acknowlege for a ETR AXI master stall initiated by the ETRSTALLREQ field. A 1 indicates that the ETR has stalled its AXI master	RO	0x0
21	etrstallreq	Software writes this field 1 to request to the ETR that it stalls its AXI master to the L3 Interconnect. Software waits for the ETRSTALLACK to be 1 and then writes this field to 0. Note that it is possible for the ETR to never assert ETRSTALLACK so software should timeout if ETRSTALLACK is never asserted.	RW	0x0

Bit	Name	Description	Access	Reset
20	etrstallen	This field controls whether the ETR is requested to idle its AXI master interface (i.e. finish outstanding transactions and not initiate any more) to the L3 Interconnect before a warm or debug reset. If set to 1, the Reset Manager makes a request to the ETR to stall its AXI master and waits for it to finish any outstanding AXI transactions before a warm reset of the L3 Interconnect or a debug reset of the ETR. This stalling is required because the debug logic (including the ETR) is reset on a debug reset and the ETR AXI master is connected to the L3 Interconnect which is reset on a warm reset and these resets can happen independently.	RW	0x1
18	fpgahsack	This is the acknowlege (high active) that the FPGA handshake acknowledge has been received by Reset Manager.	RO	0x0
17	fpgahsreq	Software writes this field 1 to initiate handshake request to FPGA . Software waits for the FPGAHSACK to be active and then writes this field to 0. Note that it is possible for the FPGA to never assert FPGAHSACK so software should timeout in this case.	RW	0x0
16	fpgahsen	This field controls whether to perform handshake with FPGA before asserting warm reset. If set to 1, the Reset Manager makes a request to the FPGAbefore asserting warm reset signals. However if FPGA is already in warm reset state, the handshake is not performed. If set to 0, the handshake is not performed	RW	0x0
14	scanmgrhsack	This is the acknowlege (high active) that the SCAN manager has successfully idled its output clocks.	RO	0x0
13	scanmgrhsreq	Software writes this field 1 to request to the SCAN manager to idle its output clocks. Software waits for the SCANMGRHSACK to be 1 and then writes this field to 0. Note that it is possible for the Scan Manager to never assert SCANMGRHSACK (e.g. its input clock is disabled) so software should timeout in this case.	RW	0x0

Bit	Name	Description	Access	Reset
12	scanmgrhsen	Enables a handshake between the Reset Manager and Scan Manager before a warm reset. The handshake is used to warn the Scan Manager that a warm reset it coming so it can prepare for it. When the Scan Manager receives a warm reset handshake, the Scan Manager drives its output clocks to a quiescent state to avoid glitches. If set to 1, the Reset Manager makes a request to the Scan Managerbefore asserting warm reset signals. However if the Scan Manager is already in warm reset, the handshake is skipped. If set to 0, the handshake is skipped.	RW	0x0
10	fpgamgrhsack	This is the acknowlege (high active) that the FPGA manager has successfully idled its output clock.	RO	0x0
9	fpgamgrhsreq	Software writes this field 1 to request to the FPGA Manager to idle its output clock. Software waits for the FPGAMGRHSACK to be 1 and then writes this field to 0. Note that it is possible for the FPGA Manager to never assert FPGAMGRHSACK so software should timeout in this case.	RW	0x0
8	fpgamgrhsen	Enables a handshake between the Reset Manager and FPGA Manager before a warm reset. The handshake is used to warn the FPGA Manager that a warm reset it coming so it can prepare for it. When the FPGA Manager receives a warm reset handshake, the FPGA Manager drives its output clock to a quiescent state to avoid glitches. If set to 1, the Manager makes a request to the FPGA Managerbefore asserting warm reset signals. However if the FPGA Manager is already in warm reset, the handshake is skipped. If set to 0, the handshake is skipped.	RW	0x0
6	sdrselfreqack	This is the acknowlege for a SDRAM self-refresh mode request initiated by the SDRSELFREFREQ field. A 1 indicates that the SDRAM Controller Subsystem has put the SDRAM devices into self-refresh mode.	RO	0x0
5	sdrselfrefreq	Software writes this field 1 to request to the SDRAM Controller Subsystem that it puts the SDRAM devices into self-refresh mode. This is done to preserve SDRAM contents across a software warm reset. Software waits for the SDRSELFREFACK to be 1 and then writes this field to 0. Note that it is possible for the SDRAM Controller Subsystem to never assert SDRSELFREFACK so software should timeout if SDRSELFREFACK is never asserted.	RW	0x0

Bit	Name	Description	Access	Reset
4	sdrselfrefen	This field controls whether the contents of SDRAM devices survive a hardware sequenced warm reset. If set to 1, the Reset Manager makes a request to the SDRAM Controller Subsystem to put the SDRAM devices into self-refresh mode before asserting warm reset signals. However, if SDRAM is already in warm reset, Handshake with SDRAM is not performed.	RW	0x0
1	swwarmrstreq	This is a one-shot bit written by software to 1 to trigger a hardware sequenced warm reset. It always reads the value 0.	RW	0x0
0	swcoldrstreq	This is a one-shot bit written by software to 1 to trigger a cold reset. It always reads the value 0.	RW	0x0

counts

The COUNTS register is used by software to control reset behavior.It includes fields for software to control the behavior of the warm reset and nRST pin. Fields are only reset by a cold reset.

counts Fields

Bit	Name	Description	Access	Reset
27:8	nrstcnt	The Reset Manager pulls down the nRST pin on a warm reset for the number of cycles specified in this register. A value of 0x0 prevents the Reset Manager from pulling down the nRST pin.	RW	0x800

Bit	Name	Description	Access	Reset
7:0	warmrstcycles	On a warm reset, the Reset Manager releases the reset to the Clock Manager, and then waits for the number of cycles specified in this register before releasing the rest of the hardware controlled resets. Value must be greater than 16.	RW	0x80

mpumodrst

The MPUMODRST register is used by software to trigger module resets (individual module reset signals). Software explicitly asserts and de-asserts module reset signals by writing bits in the appropriate *MODRST register. It is up to software to ensure module reset signals are asserted for the appropriate length of time and are de-asserted in the correct order. It is also up to software to not assert a module reset signal that would prevent software from de-asserting the module reset signal. For example, software should not assert the module reset to the CPU executing the software. Software writes a bit to 1 to assert the module reset signal and to 0 to de-assert the module reset signal. All fields except CPU1 are only reset by a cold reset. The CPU1 field is reset by a cold reset. The CPU1 field is also reset by a warm reset if not masked by the corresponding MPUWARMMASK field.

mpumodrst Fields

Bit	Name	Description	Access	Reset
4	l2	Resets L2 cache controller	RW	0x0
3	scuper	Resets SCU and peripherals. Peripherals consist of the interrupt controller, global timer, both per-CPU private timers, and both per-CPU watchdogs (except for the Watchdog Reset Status registers).	RW	0x0
2	wds	Resets both per-CPU Watchdog Reset Status registers in MPU.	RW	0x0

Bit	Name	Description	Access	Reset
1	cpu1	Resets Cortex-A9 CPU1 in MPU. It is reset to 1 on a cold or warm reset. This holds CPU1 in reset until software is ready to release CPU1 from reset by writing 0 to this field. On single-core devices, writes to this field are ignored.On dual-core devices, writes to this field trigger the same sequence as writes to the CPU0 field (except the sequence is performed on CPU1).	RW	0x1
0	cpu0	Resets Cortex-A9 CPU0 in MPU. Whe software changes this field from 0 to 1, ittriggers the following sequence: 1. CPU0 reset is asserted. cpu0 clkoff is de-asserted 2. after 32 osc1_clk cycles, cpu0 clkoff is asserted. When software changes this field from 1 to 0, it triggers the following sequence: 1.CPU0 reset is de-asserted. 2. after 32 cycles, cpu0 clkoff is de-asserted. Software needs to wait for at least 64 osc1_ clk cycles between each change of this field to keep the proper reset/clkoff sequence.	RW	0x0

permodrst

The PERMODRST register is used by software to trigger module resets (individual module reset signals). Software explicitly asserts and de-asserts module reset signals by writing bits in the appropriate *MODRST register. It is up to software to ensure module reset signals are asserted for the appropriate length of time and are de-asserted in the correct order. It is also up to software to not assert a module reset signal that would prevent software from de-asserting the module reset signal. For example, software should not assert the module reset to the CPU executing the software. Software writes a bit to 1 to assert the module reset signal and to 0 to de-assert the module reset signal. All fields are reset by a warm or cold reset. The reset value of all fields is 1. This holds the corresponding module in reset until software is ready to release the module from reset by writing 0 to its field.

miscmodrst

The MISCMODRST register is used by software to trigger module resets (individual module reset signals). Software explicitly asserts and de-asserts module reset signals by writing bits in the appropriate *MODRST register. It is up to software to ensure module reset signals are asserted for the appropriate length of time and are de-asserted in the correct order. It is also up to software to not assert a module reset signal that would prevent software from de-asserting the module reset signal. For example, software should not assert the module reset to the CPU executing the software. Software writes a bit to 1 to assert the module reset signal and to 0 to de-assert the module reset signal. All fields are only reset by a cold reset

Document Revision History

Table 3-11: Document Revision History

Date	Version	Changes
December 2014	2014.12.15	• Maintenance Release. • Signal power information added to HPS External Reset Sources section. • Updated block diagram with `h2f_dbg_rst_n` signal
June 2014	2014.06.30	• Updated "Functional Description of Reset Manager" • Added address map and register descriptions
February 2014	2014.02.28	Updated content in sections: • Reset Sequencing • Warm Reset Assertion Sequence
December 2013	2013.12.30	Minor formatting issues
November 2012	1.2	• Added cold and warm reset timing diagrams. • Minor updates.
May 2012	1.1	Added reset controller, functional description, and address map and register definitions sections.
January 2012	1.0	Initial release.

FPGA Manager

4

2014.12.15

av_5v4

The FPGA manager in the hard processor system (HPS) manages and monitors the FPGA portion of the system on a chip (SoC) device. The FPGA manager can configure the FPGA fabric from the HPS, monitor the state of the FPGA, and drive or sample signals to or from the FPGA fabric.

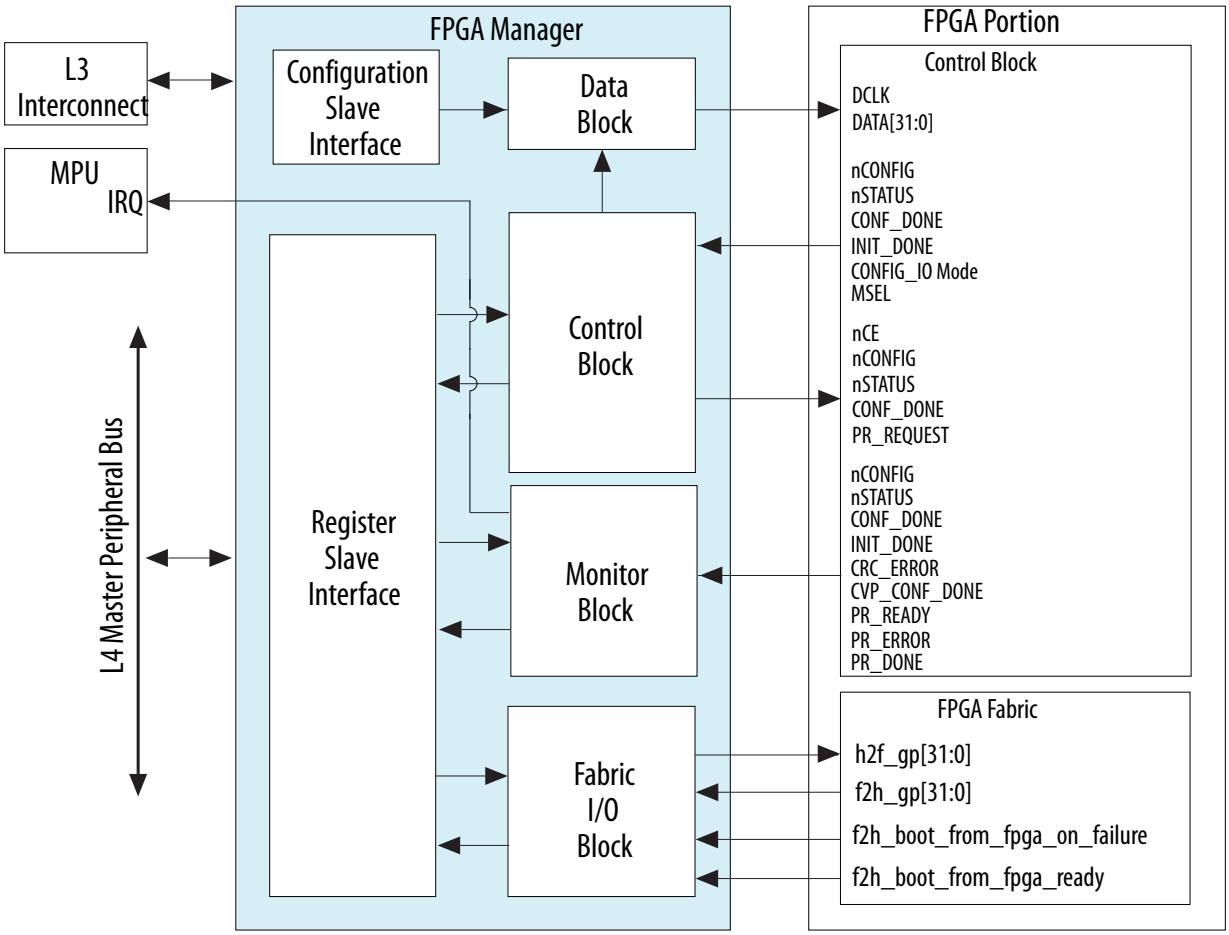
Features of the FPGA Manager

The FPGA manager provides the following functionality and features:

- Full configuration and partial reconfiguration of the FPGA portion of the SoC device
- Drives 32 general-purpose output signals to the FPGA fabric
- Receives 32 general-purpose input signals from the FPGA fabric
- Receives two boot handshaking input signals from the FPGA fabric (used when the HPS boots from the FPGA)
- Monitors the FPGA configuration and power status
- Generates interrupts based on the FPGA status changes
- Can reset the FPGA

FPGA Manager Block Diagram and System Integration

Figure 4-1: FPGA Manager Block Diagram



The register slave interface connects to the level 4 (L4) master peripheral bus for control and status register (CSR) access. The configuration slave interface connects to the level 3 (L3) interconnect for the microprocessor unit (MPU) subsystem or other masters to write the FPGA configuration image to the FPGA control block (CB) when configuring the FPGA portion of the SoC device.

The general-purpose I/O and boot handshake input interfaces connect to the FPGA fabric. The FPGA manager also connects to the FPGA CB signals to monitor and control the FPGA portion of the device.

The FPGA manager consists of the following blocks:

- Configuration slave interface—accepts and transfers the configuration image to the data interface.
- Register slave interface—accesses the CSRs in the FPGA manager.
- Data—accepts the FPGA configuration image from the configuration slave interface and sends it to the FPGA CB.
- Control—controls the FPGA CB.
- Monitor—monitors the configuration signals in the FPGA CB and sends interrupts to the MPU subsystem.
- Fabric I/O—reads and writes signals from or to the FPGA fabric.

Functional Description of the FPGA Manager

FPGA Manager Building Blocks

The FPGA manager has the two blocks - fabric I/O and monitor.

Related Information

FPGA Manager Address Map and Register Definitions on page 4-9

Fabric I/O

The fabric I/O block contains the following registers to allow simple low-latency communication between the HPS and the FPGA fabric:

- General-purpose input register (`gpi`)
- General-purpose output register (`gpo`)
- Boot handshaking input register (`misci`)

These registers are only valid when the FPGA is in user mode. Reading from these registers while the FPGA is not in user mode provides undefined data.

The 32 general-purpose input signals from the FPGA fabric are read by reading the `gpi` register using the register slave interface. The 32 general-purpose output signals to the FPGA fabric are generated from writes to the `gpo` register. For more information about FPGA manager registers, refer to **FPGA Manager Address Map and Register Definitions** on page 4-9.

The boot handshake input signals from the FPGA fabric are read by reading the `misci` register. The `f2h_boot_from_fpga_ready` signal indicates that the FPGA fabric is ready to send proloader information to the boot ROM. The `f2h_boot_from_fpga_on_failure` signal serves as a fallback in the event that the boot ROM code fails to boot from the primary boot flash device. In this case, the boot ROM code checks these two handshaking signals to determine if it should use the boot code hosted in the FPGA memory as the next stage in the boot process.

There is no interrupt support for this block.

Related Information

FPGA Manager Address Map and Register Definitions on page 4-9

Monitor

The monitor block is an instance of the Synopsys DesignWareGPIO IP (DW_apb_gpio), which is a separate instance of the IP that comprises the three HPS GPIO interfaces. The monitor block connects to the configuration signals in the FPGA. This block monitors key signals related to FPGA configuration such as INIT_DON E, CRC_ERROR, and PR_DONE. Software configures the monitor block through the register slave interface, and can either poll FPGA signals or be interrupted. The **mon** address map within the FPGA manager register address map contains the monitor registers. For more information about FPGA manager registers, refer to **FPGA Manager Address Map and Register Definitions** on page 4-9

You can program the FPGA manager to treat any of the monitor signals as interrupt sources. Independent of the interrupt source type, the monitor block always drives an active-high level interrupt to the MPU. Each interrupt source can be of the following types:

- Active-high level
- Active-low level
- Rising edge
- Falling edge

FPGA Configuration

You can configure the FPGA using an external device or through the HPS. This section highlights configuring the FPGA through the HPS.

The FPGA CB uses the FPGA mode select (MSEL) pins to determine which configuration scheme to use. The MSEL pins must be tied to the appropriate values for the configuration scheme. The table below lists supported MSEL values when the FPGA is configured by the HPS.

Table 4-1: Configuration Schemes for FPGA Configuration by the HPS

Configura-tion Scheme	Compres-sion Feature	Design Security Feature	POR Delay [8]	MSEL[4..0] [9]	cfgwdth	cdratio	Supports Partial Reconfiguration
FPP ×16	Disabled	AES Disabled	Fast	00000	0	1	Yes
			Standard	00100	0	1	Yes
	Disabled	AES Enabled	Fast	00001	0	2	Yes
			Standard	00101	0	2	Yes
	Enabled	Optional [10]	Fast	00010	0	4	Yes
			Standard	00110	0	4	Yes

Configuration Scheme	Compression Feature	Design Security Feature	POR Delay [8]	MSEL[4..0] [9]	cfgwdth	cdratio	Supports Partial Reconfiguration
FPP ×32	Disabled	AES Disabled	Fast	01000	1	1	No
			Standard	01100	1	1	No
	Disabled	AES Enabled	Fast	01001	1	4	No
			Standard	01101	1	4	No
	Enabled	Optional [11]	Fast	01010	1	8	No
			Standard	01110	1	8	No

HPS software sets the clock-to-data ratio field (`cdratio`) and configuration data width bit (`cfgwdth`) in the control register (`ctrl`) to match the `MSEL` pins. The `cdratio` field and `cfgwdth` bit must be set before the start of configuration.

The FPGA manager connects to the configuration logic in the FPGA portion of the device using a mode similar to how external logic (for example, MAX II or an intelligent host) configures the FPGA in fast passive parallel (FPP) mode. FPGA configuration through the HPS supports all the capabilities of FPP mode, including the following items:

- FPGA configuration
- Partial FPGA reconfiguration
- FPGA I/O configuration, followed by PCI Express® (PCIe) configuration of the remainder of FPGA
- External single event upset (SEU) scrubbing
- Decompression
- Advanced Encryption Standard (AES) encryption
- FPGA `DCLK` clock used for initialization phase clock

Note: The FPGA manager supports a data width of 16 or 32 bits. When configuring the FPGA fabric from the HPS, Altera recommends that you always set the data width to 32 bits. For partial reconfiguration, the 16-bit data width is the only option.

(8) For information about POR delay, refer to the Configuration, Design Security, and Remote System Upgrades in the Arria V Device Handbook, Volume 1.
(9) Other MSEL values are allowed when the FPGA is configured from a non-HPS source. For information, refer to the Configuration, DesignSecurity, and Remote System Upgrades in the Arria V Device Handbook, Volume 1.
(10) You can select to enable or disable this feature.
(11) You can select to enable or disable this feature.

Configuring the FPGA portion of the SoC device comprises the following phases:

1. Power up phase
2. Reset phase
3. Configuration phase
4. Initialization phase
5. User mode

The FPGA Manager can be configured to accept configuration data directly from the MPU or the DMA engine. Either the processor or the DMA engine moves data from memory to the FPGA Manager data image register space `img_data_w`. The L4 interconnect allocates a 4 KB region for image data. It is not necessary to increment the address when writing the image data because all accesses within the 4 KB image data region will be transferred to the configuration logic.

Related Information

  For more information about configuring the FPGA through the HPS, refer to the *Configuration, Design Security, and Remote System Upgrade* appendix in the Arria V Device Handbook, Volume 1.
- **Booting and Configuration** on page 29-1

Power Up Phase

In this phase, the VCC is ramping up and has yet to reach normal levels. This phase completes when the on-chip voltage detector determines that the VCC has reached normal levels.

Reset Phase

The FPGA manager resets the FPGA portion of the SoC device when the FPGA configuration signal (`nCONFIG`) is driven low. The HPS configures the FPGA by writing a 1 to the `nconfigpull` bit of the `ctrl` register. This action causes the FPGA portion of the device to reset and perform the following actions:

1. Clear the FPGA configuration RAM bits
2. Tri-state all FPGA user I/O pins
3. Pull the `nSTATUS` and `CONF_DONE` pins low
4. Use the FPGA CB to read the values of the `MSEL` pins to determine the configuration scheme

The `nconfigpull` bit of the `ctrl` register needs to be set to 0 when the FPGA has successfully entered the reset phase. Setting the bit releases the FPGA from the reset phase and transitions to the configuration phase.

Note: You must set the `cdratio` and `cfgwdth` bits of the `ctrl` register appropriately before the FPGA enters the reset phase.

Configuration Phase

To configure the FPGA using the HPS, software sets the `axicfgen` bit of the `ctrl` register to 1. Software then sends configuration data to the FPGA by writing data to the write data register (`data`) in the FPGA manager module configuration data address map. Software polls the `CONF_DONE` pin by reading the `gpio_instatus` register to determine if the FPGA configuration is successful. When configuration is successful, software sets the `axicfgen` bit of the `ctrl` register to 0. The FPGA user I/O pins are still tri-stated in this phase.

After successfully completing the configuration phase, the FPGA transitions to the initialization phase. To delay configuring the FPGA, set the `confdonepull` bit of the `ctrl` register to 1.

Related Information

Booting and Configuration on page 29-1

Initialization Phase

In this phase, the FPGA prepares to enter user mode. The internal oscillator in the FPGA portion of the device is the default clock source for the initialization phase. Alternatively, the configuration image can specify the `CLKUSR` or the `DCLK` pins as the clock source. The alternate clock source controls when the FPGA enters user mode.

If `DCLK` is selected as the clock source, software uses the `DCLK` count (`dclkcnt`) register to drive `DCLK` pulses to the FPGA. Writing to the `cnt` field of the `dclkcnt` register triggers the FPGA manager to generate the specified number of `DCLK` pulses. When all of the `DCLK` pulses have been sent, the `dcntdone` bit of the `DCLK` status (`dclkstat`) register is set to 1. Software polls the `dcntdone` bit to know when all of the `DCLK` pulses have been sent.

Note: Before another write to the `dclkcnt` register, software needs to write a value of 1 to the `dcntdone` bit to clear the done state.

The FPGA user I/O pins are still tri-stated in this phase. When the initialization phase completes, the FPGA releases the optional `INIT_DONE` pin and an external resistor pulls the pin high.

User Mode

The FPGA enters the user mode after exiting the initialization phase. The FPGA user I/O pins are no longer tri-stated in this phase and the configured soft logic in the FPGA becomes active.

The FPGA remains in user mode until the `nCONFIG` pin is driven low. If the `nCONFIG` pin is driven low, the FPGA reenters the reset phase. The internal oscillator is disabled in user mode, but is enabled as soon as the `nCONFIG` pin is driven low.

Related Information

- **Configuration, Design Security, and Remote System Upgrades in Cyclone V Devices**
  For more information about configuring the FPGA through the HPS, refer to the *Configuration, Design Security, and Remote System Upgrade* appendix in the Arria V Device Handbook, Volume 1.
- **Booting and Configuration** on page 29-1

FPGA Status

Configuration signals from the FPGA CSS such as `INIT_DONE`, `CRC_ERROR` and `PR_DONE` are monitored by the FPGA Manager. Software configures the monitor block through the register slave interface, and can either poll FPGA signals or be interrupted. Monitored signals can be read through the `imgcfg_stat` register as well as the `intr_masked_status` register. Each of the monitored signals can generate an interrupt to the MPU Global Interrupt Controller. Each interrupt source can be enabled and the polarity of the signals generating the interrupt can also be selected through the `intr_mask` and `intr_polarity` registers in the FPGA Manager.

Error Message Extraction

Cyclic redundancy check (CRC) errors from the FPGA fabric are monitored by the FPGA Manager. Upon assertion of a CRC error signal from the FPGA, the FPGA Manager extracts information about the error including:

- Error syndrome
- Error location
- Error type

A CRC error interrupt from the FPGA Manager can be enabled through software. Software can then extract the CRC error information from the Error Message Register (EMR) data interface. The number of valid error information bits in the EMR data registers depends on the specific FPGA device.

JTAG Hosting

The FPGA Manager has the capability to host the JTAG interface to the FPGA CSS. In this mode the FPGA Manager controls the FPGA JTAG interface to CSS through mux overrides thus bypassing the JTAG device pins. This interface is disabled by default. When JTAG hosting is enabled, the FPGA Manager also provides a JTAG interface to the FPGA core which could be used by soft logic in the FPGA.

JTAG hosting provides the capability for:

- Secure remote debug
- Secure remote key insertion
- Remote FPGA configuration

Boot Handshake

There are two input signals from the FPGA to control HPS boot from the FPGA. Both are synchronized within the FPGA Manager. Boot software reads these signals before accessing a boot image in the FPGA. The following table describes the functionality of these signals.

Signal	Description
f2h_boot_from_fpga_on_failure	Indicates whether a fallback preloader image is available in the FPGA on-chip RAM at memory location 0x0. The fallback preloader image is used only if the HPS boot ROM does not find a valid preloader image in the selected flash memory device.
f2h_boot_from_fpga_ready	Indicates a preloader image is available in an FPGA on-chip RAM at memory location 0x0 and it is ready to be accessed.

General Purpose I/O

Thirty-two general purpose inputs and thirty-two general purpose outputs are provided to the FPGA and are controlled through registers in the FPGA Manager.

No interrupts are generated through the input pins. All inputs are synchronized within the FPGA Manager. Output signals should be synchronized in the FPGA.

Clock

The FPGA manager has two clock input signals which are asynchronous to each other. The clock manager generates these two clocks:

- `cfg_clk`—the configuration slave interface clock input and also the `DCLK` output reference for FPGA configuration. Enable this clock in the clock manager only when configuration is active or when the configuration slave interface needs to respond to master requests.
- `l4_mp_clk`—the register slave interface clock.

Related Information

Clock Manager on page 2-1

Reset

The FPGA manager has the `fpga_manager_rst_n` reset signal. The reset manager drives this signal to the FPGA manager on a cold or warm reset. All distributed reset signals in the FPGA manager are asserted asynchronously at the same time and deasserted synchronously to their associated clocks.

Related Information

Reset Manager on page 3-1

FPGA Manager Address Map and Register Definitions

The address map and register definitions for the FPGA Manager consist of the following regions:

- FPGA Manager Module
- FPGA Manager Module Configuration Data

FPGA Manager Module Configuration Data

Register	Offset	Width	Access	Reset Value	Description
data on page 4-10	0x0	32	RW	0x0	Write Data Register

data

Used to send configuration image to FPGA. The DATA register accepts 4 bytes of the configuration image on each write. The configuration image byte-stream is converted into a 4-byte word with little-endian ordering. If the configuration image is not an integer multiple of 4 bytes, software should pad the configuration image with extra zero bytes to make it an integer multiple of 4 bytes. The FPGA Manager converts the DATA to 16 bits wide when writing CB.DATA for partial reconfiguration. The FPGA Manager waits to transmit the data to the CB until the FPGA is able to receive it. For a full configuration, the FPGA Manager waits until the FPGA exits the Reset Phase and enters the Configuration Phase. For a partial reconfiguration, the FPGA Manager waits until the CB.PR_READY signal indicates that the FPGA is ready.

stat

Provides status fields for software for the FPGA Manager. The Mode field tells software what configuration phase the FPGA currently is in. For regular configuration through the PINs or through the HPS, these states map directly to customer configuration documentation. For Configuration Via PCI Express (CVP), the IOCSR configuration is done through the PINS or through HPS. Then the complete configuration is done through the PCI Express Bus. When CVP is being done, InitPhase indicates only IOCSR configuration has completed. CVP_CONF_DONE is available in the CB Monitor for observation by software. The MSEL field provides a read only register for software to read the MSEL value driven from the external pins.

ctrl

Allows HPS to control FPGA configuration. The NCONFIGPULL, NSTATUSPULL, and CONFDONEPULL fields drive signals to the FPGA Control Block that are logically ORed into their respective pins. These signals are always driven independent of the value of EN. The polarity of the NCONFIGPULL, NSTATUSPULL, and CONFDONEPULL fields is inverted relative to their associated pins. The MSEL (external pins), CDRATIO and CFGWDTH signals determine the mode of operation for Normal Configuration. For Partial Reconfiguration, CDRATIO is used to set the appropriate clock to data ratio, and CFGWDTH should always be set to 16-bit Passive Parallel. AXICFGEN is used to enable transfer of configuration data by enabling or disabling DCLK during data transfers.

9	cfgwdth	This field determines the Configuration Passive Parallel data bus width when HPS configures the FPGA. Only 32-bit Passive Parallel or 16-bit Passive Parallel are supported. When HPS does Normal Configuration, configuration should use 32-bit Passive Parallel Mode. The external pins MSEL must be set appropriately for the configuration selected. For Partial Reconfiguration, 16-bit Passive Parallel must be used. **Value** — **Description** 0x0 — 16-bit Passive Parallel 0x1 — 32-bit Passive Parallel	RW	0x1
8	axicfgen	There are strict SW initialization steps for configuration, partial configuration and error cases. When SW is sending configuration files, this bit must be set before the file is transferred on the AXI bus. This bit enables the DCLK during the AXI configuration data transfers. Note, the AXI and configuration datapaths remain active irregardless of the state of this bit. Simply, if the AXI slave is enabled, the DCLK to the CB will be active. If disabled, the DCLK to the CB will not be active. So AXI transfers destined to the FPGA Manager when AXIEN is 0, will complete normally from the HPS perspective. This field only affects the FPGA if CTRL.EN is 1. **Value** — **Description** 0x0 — Incoming AXI data transfers will be ignored. DCLK will not toggle during data transfer. 0x1 — AXI data transfer to CB is active. DCLK will toggle during data transfer.	RW	0x0

Bit	Name	Description	Access	Reset
7:6	cdratio	This field controls the Clock to Data Ratio (CDRATIO) for Normal Configuration and Partial Reconfiguration data transfer from the AXI Slave to the FPGA. For Normal Configuration, the value in this field must be set to be consistent to the implied CD ratio of the MSEL setting. For Partial Reconfiguration, the value in this field must be set to the same clock to data ratio in the options bits in the Normal Configuration file. **Value** / **Description** 0x0 — CDRATIO of 1 0x1 — CDRATIO of 2 0x2 — CDRATIO of 4 0x3 — CDRATIO of 8	RW	0x0
5	prreq	This field is used to assert PR_REQUEST to request partial reconfiguration while the FPGA is in User Mode. This field only affects the FPGA if CTRL.EN is 1. **Value** / **Description** 0x0 — De-assert PR_REQUEST (driven to 0). 0x1 — Assert PR_REQUEST (driven to 1).	RW	0x0
4	confdonepull	Pulls down CONF_DONE input to the CB **Value** / **Description** 0x0 — Don't pull-down CONF_DONE input to the CB. 0x1 — Pull-down CONF_DONE input to the CB.	RW	0x0
3	nstatuspull	Pulls down nSTATUS input to the CB **Value** / **Description** 0x0 — Don't pull-down nSTATUS input to the CB. 0x1 — Pull-down nSTATUS input to the CB.	RW	0x0

Bit	Name	Description	Access	Reset
2	nconfigpull	The nCONFIG input is used to put the FPGA into its reset phase. If the FPGA was configured, its operation stops and it will have to be configured again to start operation. **Value** **Description** 0x0 Don't pull-down nCONFIG input to the CB. 0x1 Pull-down nCONFIG input to the CB. This puts the FPGA in reset phase and restarts configuration.	RW	0x0
1	nce	This field drives the active-low Chip Enable (nCE) signal to the CB. It should be set to 0 (configuration enabled) before CTRL.EN is set. This field only effects the FPGA if CTRL.EN is 1. **Value** **Description** 0x0 Configuration is enabled. The nCE to the CB is driven to 0. 0x1 Configuration is disabled. The nCE to the CB is driven to 1.	RW	0x0
0	en	Controls whether the FPGA configuration pins or HPS FPGA Manager drive configuration inputs to the CB. **Value** **Description** 0x0 FPGA configuration pins drive configuration inputs to the CB. Used when FPGA is configured by means other than the HPS. 0x1 FPGA Manager drives configuration inputs to the CB. Used when HPS configures the FPGA.	RW	0x0

dclkcnt

Used to give software control in enabling DCLK at any time. SW will need control of the DCLK in specific configuration and partial reconfiguration initialization steps to send spurious DCLKs required by the CB. SW takes ownership for DCLK during normal configuration, partial reconfiguration, error scenerio handshakes including SEU CRC error during partial reconfiguration, SW early abort of partial reconfiguration, and initializatin phase DCLK driving. During initialization phase, a configuration image loaded into the FPGA can request that DCLK be used as the initialization phase clock instead of the default internal oscillator or optionally the CLKUSR pin. In the case that DCLK is requested, the DCLKCNT register is used by software to control DCLK during the initialization phase. Software should poll the DCLKSTAT.DCNTDONE write one to clear register to be set when the correct number of

DCLKs have completed. Software should clear DCLKSTAT.DCNTDONE before writing to the DCLKCNT register again. This field only affects the FPGA if CTRL.EN is 1.

dclkcnt Fields

Bit	Name	Description	Access	Reset
31:0	cnt	Controls DCLK counter. Software writes a non-zero value into CNT and the FPGA Manager generates the specified number of DCLK pulses and decrements COUNT. This register will read back the original value written by software. Software can write CNT at any time.	RW	0x0

dclkstat

This write one to clear register indicates that the DCLKCNT has counted down to zero. The DCLKCNT is used by software to drive spurious DCLKs to the FPGA. Software will poll this bit after writing DCLKCNT to know when all of the DCLKs have been sent.

Configuration Monitor (MON) Registers Register Descriptions

The Configuration Monitor allows software to poll or be interrupted by changes in the FPGA state. The Configuration Monitor is an instantiation of a Synopsys GPIO.
Only registers relevant to the MON operation are shown. The GPIO inputs are connected to the following signals:

- nSTATUS - Driven to 0 by the FPGA in this device if the FPGA is in Reset Phase or if the FPGA detected an error during the Configuration Phase.
- CONF_DONE - Driven to 0 by the FPGA in this device during the Reset Phase and driven to 1 when the FPGA Configuration Phase is done.
- INIT_DONE - Driven to 0 by the FPGA in this device during the Configuration Phase and driven to 1 when the FPGA Initialization Phase is done.
- CRC_ERROR - CRC error indicator. A CRC_ERROR value of 1 indicates that the FPGA detected a CRC error while in User Mode.
- CVP_CONF_DONE - Configuration via PCIe done indicator. A CVP_CONF_DONE value of 1 indicates that CVP is done.
- PR_READY - Partial reconfiguration ready indicator. A PR_READY value of 1 indicates that the FPGA is ready to receive partial reconfiguration or external scrubbing data.
- PR_ERROR - Partial reconfiguration error indicator. A PR_ERROR value of 1 indicates that the FPGA detected an error during partial reconfiguration or external scrubbing.
- PR_DONE - Partial reconfiguration done indicator. A PR_DONE value of 1 indicates partial reconfiguration or external scrubbing is done.
- nCONFIG Pin - Value of the nCONFIG pin. This can be pulled-down by the FPGA in this device or logic external to this device connected to the nCONFIG pin. See the description of the nCONFIG field in this register to understand when the FPGA in this device pulls-down the nCONFIG pin. Logic external to this device pulls-down the nCONFIG pin to put the FPGA into the Reset Phase.

- nSTATUS Pin - Value of the nSTATUS pin. This can be pulled-down by the FPGA in this device or logic external to this device connected to the nSTATUS pin. See the description of the nSTATUS field in this register to understand when the FPGA in this device pulls-down the nSTATUS pin. Logic external to this device pulls-down the nSTATUS pin during Configuration Phase or Initialization Phase if it detected an error.
- CONF_DONE Pin - Value of the CONF_DONE pin. This can be pulled-down by the FPGA in this device or logic external to this device connected to the CONF_DONE pin. See the description of the CONF_DONE field in this register to understand when the FPGA in this device pulls-down the CONF_DONE pin. See FPGA documentation to determine how logic external to this device drives CONF_DONE.
- FPGA_POWER_ON - FPGA powered on indicator
  - 0 = FPGA portion of device is powered off.
  - 1 = FPGA portion of device is powered on.

Offset: `0x800`

gpio_inten on page 4-23
Allows each bit of Port A to be configured to generate an interrupt or not.

gpio_intmask on page 4-25
This register has 12 individual interrupt masks for the MON. Controls whether an interrupt on Port A can create an interrupt for the interrupt controller by not masking it. By default, all interrupts bits are unmasked. Whenever a 1 is written to a bit in this register, it masks the interrupt generation capability for this signal; otherwise interrupts are allowed through. The unmasked status can be read as well as the resultant status after masking.

gpio_inttype_level on page 4-28
The interrupt level register defines the type of interrupt (edge or level) for each GPIO input.

gpio_int_polarity on page 4-31
Controls the polarity of interrupts that can occur on each GPIO input.

gpio_intstatus on page 4-34
Reports on interrupt status for each GPIO input. The interrupt status includes the effects of masking.

gpio_raw_intstatus on page 4-36
Reports on raw interrupt status for each GPIO input. The raw interrupt status excludes the effects of masking.

gpio_porta_eoi on page 4-39
This register is written by software to clear edge interrupts generated by each individual GPIO input. This register always reads back as zero.

gpio_ext_porta on page 4-41
Reading this register reads the values of the GPIO inputs.

gpio_ls_sync on page 4-42
The Synchronization level register is used to synchronize inputs to the l4_mp_clk. All MON interrupts are already synchronized before the GPIO instance so it is not necessary to setup this register to enable synchronization.

gpio_ver_id_code on page 4-43
GPIO Component Version

gpio_config_reg2 on page 4-44
Specifies the bit width of port A.

gpio_config_reg1 on page 4-45
Reports settings of various GPIO configuration parameters

gpio_inten

Allows each bit of Port A to be configured to generate an interrupt or not.

January 2012	1.0	Initial release.

System Manager 5

2014.12.15

av_5v4 Subscribe Send Feedback

The system manager in the hard processor system (HPS) contains memory-mapped control and status registers (CSRs) and logic to control system level functions as well as other modules in the HPS.

The system manager connects to the following modules in the HPS:

- Direct memory access (DMA) controller
- Ethernet media access controllers (EMAC0 and EMAC1)
- Microprocessor unit (MPU) subsystem
- NAND flash controller
- Secure Digital/MultiMediaCard (SD/MMC) controller
- Quad serial peripheral interface (SPI) flash controller
- USB 2.0 On-The-Go (OTG) controllers (USB0 and USB1)
- Watchdog timers

Features of the System Manager

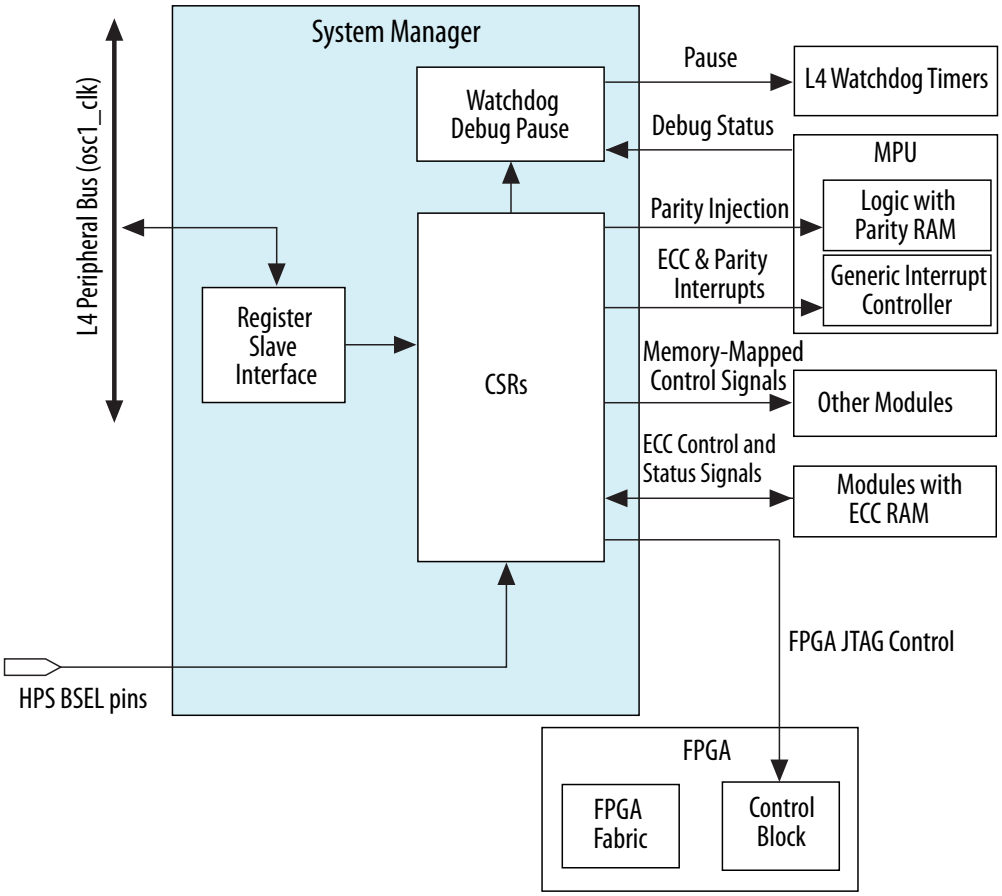
Software accesses the CSRs in the system manager to control and monitor various functions in other HPS modules that require external control signals. The system manager connects to these modules to perform the following functions:

- Sends pause signals to pause the watchdog timers when the processors in the MPU subsystem are in debug mode
- Selects the EMAC level 3 (L3) master signal options.
- Freezes the I/O pins after the HPS comes out of cold reset and during serial configuration.
- Selects the SD/MMC controller clock options and L3 master signal options.
- Selects the NAND flash controller bootstrap options and L3 master signal options.
- Selects USB controller L3 master signal options.
- Provides control over the DMA security settings when the HPS exits from reset.
- Provides boot source and clock source information that can be read during the boot process.
- Provides the capability to enable or disable an interface to the FPGA.
- Routes parity failure interrupts from the L1 caches to the Global Interrupt Controller.
- Sends error correction code (ECC) enable signals to all HPS modules with ECC-protected RAM.
- Provides the capability to inject errors during testing in the MPU L2 ECC-protected RAM.

System Manager Block Diagram and System Integration

The system manager connects to the level 4 (L4) bus through a slave interface. The CSRs connect to signals in the FPGA and other HPS modules.

Figure 5-1: System Manager Block Diagram



The system manager consists of the following blocks:

- CSRs—Provide memory-mapped access to control signals and status for the following HPS modules:
  - EMACs
  - Debug core
  - SD/MMC controller
  - NAND controller
  - USB controllers
  - DMA controller
  - System interconnect
  - ECC and parity interrupt routing to the MPU
  - Status information received from other HPS modules
- Slave port interface—provides access to system manager CSRs for connected masters.
- Watchdog debug pause—accepts the debug mode status from the MPU subsystem and pauses the L4 watchdog timers.
- Reset Manager— system manager recives the reset signals from reset manager.
- Bsel interface—Bsel from I/O or Fuse is sampled by the system manager on a cold reset de-assertion.

Functional Description of the System Manager

The system manager serves the following purposes:

- Provides software access to boot configuration and system information
- Provides software access to control and status signals in other HPS modules
- Provides combined ECC status and interrupt from other HPS modules with ECC-protected RAM
- Enables and disables HPS peripheral interfaces to the FPGA
- Provides eight registers that software can use to pass information between boot stages

Boot Configuration and System Information

The system manager provides boot configuration information through the `bootinfo` register. Sampled value of the HPS boot select (`BSEL`) pins are available to the Boot ROM software.

The boot source is determined by a combination of the `BSEL` pins and a fuse bit that can bypass the `BSEL` pins.

Related Information

Booting and Configuration on page 29-1

Additional Module Control

Each module in the HPS has its own CSRs, providing access to the internal state of the module. The system manager CSRs provide access to additional module state information, enabling additional control and monitoring. To fully control each module, you must manipulate both the peripheral's CSR and its corresponding CSR in the System Manager. This section describes system manager CSR usage for each module.

DMA Controller

The security state of the DMA controller is controlled by the manager thread security (`mgr_ns`) and interrupt security (`irq_ns`) bits of the DMA register.

The `periph_ns` register bits determine if a peripheral request interface is secure or non-secure.

Note: The `periph_ns` register bits must be configured before the DMA is released from global reset.

Related Information

DMA Controller on page 16-1

NAND Flash Controller

The bootstrap control register (`nand_bootstrap`) modifies the default behavior of the NAND flash controller after reset. The NAND flash controller samples the bootstrap control register bits when it comes out of reset.

The following `nand_bootstrap` register bits control configuration of the NAND flash controller:

- Bootstrap inhibit initialization bit (`noinit`)—inhibits the NAND flash controller from initializing when coming out of reset, and allows software to program all registers pertaining to device parameters such as page size and width.
- Bootstrap 512-byte device bit (`page512`)—informs the NAND flash controller that a NAND flash device with a 512-byte page size is connected to the system.
- Bootstrap inhibit load block 0 page 0 bit (`noloadb0p0`)—inhibits the NAND flash controller from loading page 0 of block 0 of the NAND flash device during the initialization procedure.
- Bootstrap two row address cycles bit (`tworowaddr`)—informs the NAND flash controller that only two row address cycles are required instead of the default three row address cycles.

You can use the system manager's `l3master` register to control the NAND's `ARCACHE` and`AWCACHE` signals, by setting or clearing the (`arache`) and (`awcache`) bits. These bits define the cache attributes for the master transactions of the DMA engine in the NAND controller.

Note: Register bits must be accessed only when the master interface is guaranteed to be in an inactive state.

Related Information

NAND Flash Controller on page 13-1

EMAC

The system manager allows software to select either `emac_ptp_clk` from the Clock Manager or `f2s_ptp_ref_clk` from the FPGA fabric as the source of the IEEE 1588 reference clock for each EMAC.

You can use the system manager's `l3master` register to control the EMAC's `ARCACHE` and`AWCACHE` signals, by setting or clearing the (`arcache, awcache`) and (`arprot, awprot`) bits. These bits define the cache attributes for the master transactions of the DMA engine in the EMAC controllers.

Note: Register bits must be accessed only when the master interface is guaranteed to be in an inactive state.

The app_clk_sel bit determines the source of the application clocks. The ptp_ref_sel bit selects if the timestamp reference is internally or externally generated. The ptp_ref_sel bit must be set to the correct value before the EMAC core is pulled out of reset.

Note: EMAC0 must be set to internal timestamp. The phy_intf_sel bit is programmed to select between a GMII (MII), RGMII or RMII PHY interface when the peripheral is released from reset.

Related Information

- **Clock Manager** on page 2-1
  For more information, refer to the Clock Manager chapter in the Arria V Device Handbook, Volume 3.
- **Ethernet Media Access Controller** on page 17-1

USB 2.0 OTG Controller

Registers in the system manager control the HPROT field of the USB master port of the USB 2.0 OTG Controller.

Note: Register bits should be accessed only when the master interface is guaranteed to be in an inactive state.

Related Information

USB 2.0 OTG Controller on page 18-1

SD/MMC Controller

Registers in the system manager control the HPROT field of the SD/MMC master port.

Note: Register bits should be accessed only when the master interface is guaranteed to be in an inactive state.

The system manager allows software to select the clock's phase shift for cclk_in_drv and cclk_in_sample by setting the drive clock phase shift select (drvsel) and sample clock phase shift select (smplsel) bits of the sdmmc register.

Related Information

SD/MMC Controller on page 14-1

Watchdog Timer

The system manager controls the watchdog timer behavior when the CPUs are in debug mode. The system manager sends a pause signal to the watchdog timers depending on the setting of the debug mode bits of the L4 watchdog debug register (wddbg). Each watchdog timer built into the MPU subsystem is paused when its associated CPU enters debug mode.

Related Information

Watchdog Timer on page 24-1

Boot ROM Code

Registers in the system manager control whether the boot ROM code configures the pin multiplexing for boot pins after a warm reset. Set the warm-reset-configure-pin-multiplex for boot pins bit (warmrstcfg-pinmux) of the boot ROM code register to enable or disable this control.

Note: The boot ROM code always configures the pin multiplexing for boot pins after a cold reset.

Registers in the system manager also control whether the boot ROM code configures the I/O pins used during the boot process after a warm reset. Set the warm reset configure I/Os for boot pins bit (`warmrstcfgio`) of the `ctrl` register to enable or disable this control.

Note: By default, the boot ROM code always configures the I/O pins used by boot after a cold reset.

When CPU1 is released from reset and the boot ROM code is located at the CPU1 reset exception address (for a typical case), the boot ROM reset handler code reads the address stored in the CPU1 start address register (`cpu1startaddr`) and passes control to software at that address.

There can be up to four preloader images stored in flash memory. The (`initswlastld`) register contains the index of the preloader's last image that is loaded in the on-chip RAM.

The boot ROM software state register (`bootromswstate`) is a 32-bit general-purpose register reserved for the boot ROM.

The following warmram related registers are used to configure the warm reset from on-chip RAM feature and must be written by software prior to the warm reset occurring.

Table 5-1: The warmram Registers

Register	Name	Purpose
`enable`	Enable	Controls whether the boot ROM attempts to boot from the contents of the on-chip RAM on a warm reset.
`datastart`	Data start	Contains the byte offset of the warm boot CRC validation region in the on-chip RAM. The offset must be word-aligned to an integer multiple of four.
`length`	Length	Contains the length in bytes of the region in the on-chip RAM available for warm boot CRC validation.
`execution`	Execution offset	Contains the byte offset into the on-chip RAM that the boot code jumps to if the CRC validation succeeds.
`crc`	Expected CRC	Contains the expected CRC of the region in the on-chip RAM.

The number of wait states applied to the boot ROM's read operation is determined by the wait state bit (`waitstate`) of the `ctrl` register. After the boot process, software might require reading the code in the boot ROM. If software has changed the clock frequency of the `l3_main_clk` after reset, an additional wait state is necessary to access the boot ROM. Set the `waitstate` bit to add an additional wait state to the read access of the boot ROM. The enable safe mode warm reset update bit controls whether the wait state bit is updated during a warm reset.

L3 Interconnect

The System Manager provides remap bits to the L3 interconnect. These bits can remap the Boot ROM and the On-chip RAM.

FPGA Interface Enables

The system manager can enable or disable interfaces between the FPGA and HPS. The interfaces must be disabled when not in use to avoid undefined behavior.

The global interface bit (`intf`) of the global disable register (`gbl`) disables all interfaces between the FPGA and HPS.

Note: Ensure that the FPGA in configured before enabling the interfaces and that all interfaces between the FPGA and HPS are inactive before disabling them.

You can set the individual disable register (`indiv`) to disable the following interfaces between the FPGA and HPS:

- Reset request interface
- JTAG enable interface
- I/O configuration interface
- Boundary scan interface
- Debug interface
- Trace interface
- System Trace Macrocell (STM) interface
- Cross-trigger interface (CTI)
- NAND interface
- SD/MMC interface
- SPI Master interface
- EMAC interfaces

ECC and Parity Control

The system manager can enable or disable ECC for each of the following HPS modules with ECC-protected RAM:

- MPU L2 cache data RAM
- On-chip RAM
- USB 2.0 OTG controller (USB0 and USB1) RAM
- EMAC (EMAC0, EMAC1, and EMAC2) RAM
- DMA controller RAM
- NAND flash controller RAM
- Quad SPI flash controller RAM
- SD/MMC controller RAM
- DDR interfaces

The system manager can inject single-bit or double-bit errors into the MPU L2 ECC memories for testing purposes. Set the bits in the appropriate memory enable register to inject errors. For example, to inject a single bit ECC error, set the `injs` bit of the `mpu_ctrl_l2_eccregister`.

Note: The injection request is edge-sensitive, meaning that the request is latched on 0 to 1 transitions on the injection bit. The next time a write operation occurs, the data will be corrupted, containing either a single or double bit error as selected. When the data is read back, the ECC logic detects the

single or double bit error appropriately. The injection request cannot be cancelled, and the number of injections is limited to once every five MPU cycles.

The system manager can also inject parity failures into the parity-protected RAM in the MPU L2 to test the parity failure interrupt handler. Set the bits of the parity fail injection register (`parityinj`) to inject parity failures.

Note: Injecting parity failures into the parity-protected RAM in the MPU L2 causes the interrupt to be raised immediately. There is no actual error injected and the data is not corrupted. Furthermore, there is no need for a memory operation to actually be performed for the interrupt to be raised.

Preloader Handoff Information

The system manager provides eight 32-bit registers to store handoff information between the preloader and the operating system. The preloader can store any information in these registers. These register contents have no impact on the state of the HPS hardware. When the operating system kernel boots, it retrieves the information by reading the preloader to OS handoff information register array. These registers are reset only by a cold reset.

Clocks

The system manager is driven by a clock generated by the clock manager.

Related Information

Clock Manager on page 2-1
For more information, refer to the Clock Manager chapter in the Arria V Device Handbook, Volume 3.

Resets

The system manager receives two reset signals from the reset manager. The `sys_manager_rst_n` signal is driven on a cold or warm reset and the `sys_manager_cold_rst_n` signal is driven only on a cold reset. This function allows the system manager to reset some CSR fields on either a cold or warm reset and others only on a cold reset.

Related Information

Reset Manager on page 3-1

System Manager Address Map and Register Definitions

The address map and register definitions for the HPS-FPGA bridges consist of the following regions:

- System Manager Module

Related Information

- **Introduction to the Arria V Hard Processor System** on page 1-1
  The base addresses of all modules are also listed in the *Introduction to the Hard Processor System* chapter in the *Arria V Device Handbook, Volume 3*.

wddbg

Controls the behavior of the L4 watchdogs when the CPUs are in debug mode. These control registers are used to drive the pause input signal of the L4 watchdogs. Note that the watchdogs built into the MPU automatically are paused when their associated CPU enters debug mode. Only reset by a cold reset.

Module Instance	Base Address	Register Address
sysmgr	0xFFD08000	0xFFD08010

Offset: 0x10

Access: RW

FPGA Interface Group Register Descriptions

Registers used to enable/disable interfaces between the FPGA and HPS. Required for either of the following situations:[list][*]Interfaces that cannot be disabled by putting an HPS module associated with the interface into reset.[*]HPS modules that accept signals from the FPGA fabric and those signals might interfere with the normal operation of the module.[/list]. All registers are only reset by a cold reset (ignore warm reset).

Offset: 0x20

gbl on page 5-29
Used to disable all interfaces between the FPGA and HPS.

indiv on page 5-30
Used to disable individual interfaces between the FPGA and HPS.

module on page 5-33
Used to disable signals from the FPGA fabric to individual HPS modules.

gbl

Used to disable all interfaces between the FPGA and HPS.

Module Instance	Base Address	Register Address
sysmgr	0xFFD08000	0xFFD08020

Offset: 0x20

Access: RW

Bit Fields

Reserved															intf RW 0x1

gbl Fields

Bit	Name	Description	Access	Reset
0	intf	Used to disable all interfaces between the FPGA and HPS. Software must ensure that all interfaces between the FPGA and HPS are inactive before disabling them. **Value** **Description** 0x0 All interfaces between FPGA and HPS are disabled. 0x1 Interfaces between FPGA and HPS are not all disabled. Interfaces can be indivdually disabled by putting the HPS module associated with the interface in reset using registers in the Reset Manager or by using registers in this register group of the System Manager for interfaces without an associated module.	RW	0x1

indiv

Used to disable individual interfaces between the FPGA and HPS.

Module Instance	Base Address	Register Address
sysmgr	0xFFD08000	0xFFD08024

Offset: 0x24

Access: RW

Bit Fields

indiv Fields

Bit	Name	Description	Access	Reset
7	crosstrigintf	Used to disable the FPGA Fabric from sending triggers to HPS debug logic. Note that this doesn't prevent the HPS debug logic from sending triggers to the FPGA Fabric. **Value** **Description** 0x0 FPGA Fabric cannot send triggers. 0x1 FPGA Fabric can send triggers.	RW	0x1
6	stmeventintf	Used to disable the STM event interface. This interface allows logic in the FPGA fabric to trigger events to the STM debug module in the HPS. **Value** **Description** 0x0 STM event interface is disabled. Logic in the FPGA fabric cannot trigger STM events. 0x1 STM event interface is enabled. Logic in the FPGA fabric can trigger STM events.	RW	0x1
4	traceintf	Used to disable the trace interface. This interface allows the HPS debug logic to send trace data to logic in the FPGA fabric. **Value** **Description** 0x0 Trace interface is disabled. HPS debug logic cannot send trace data to the FPGA fabric. 0x1 Trace interface is enabled. Other registers in the HPS debug logic must be programmmed to actually send trace data to the FPGA fabric.	RW	0x1

Bit	Name	Description	Access	Reset
3	bscanintf	Used to disable the boundary-scan interface. This interface allows the FPGA JTAG TAP controller to execute boundary-scan instructions such as SAMPLE/PRELOAD, EXTEST, and HIGHZ. The boundary-scan interface must be enabled before attempting to send the boundary-scan instructions to the FPGA JTAG TAP controller. **Value** — **Description** 0x0 — Boundary-scan interface is disabled. Execution of boundary-scan instructions in the FPGA JTAG TAP controller is unsupported and produces undefined results. 0x1 — Boundary-scan interface is enabled. Execution of the boundary-scan instructions in the FPGA JTAG TAP controller is supported.	RW	0x1
2	configiointf	Used to disable the CONFIG_IO interface. This interface allows the FPGA JTAG TAP controller to execute the CONFIG_IO instruction and configure all device I/Os (FPGA and HPS). This is typically done before executing boundary-scan instructions. The CONFIG_IO interface must be enabled before attempting to send the CONFIG_IO instruction to the FPGA JTAG TAP controller. **Value** — **Description** 0x0 — CONFIG_IO interface is disabled. Execution of the CONFIG_IO instruction in the FPGA JTAG TAP controller is unsupported and produces undefined results. 0x1 — CONFIG_IO interface is enabled. Execution of the CONFIG_IO instruction in the FPGA JTAG TAP controller is supported.	RW	0x1

Bit	Name	Description	Access	Reset
1	jtagenintf	Used to disable the JTAG enable interface. The JTAG enable interface allows logic in the FPGA fabric to disable the HPS Scan Manager access to the FPGA JTAG chain. **Value** **Description** 0x0 JTAG enable interface is disabled. Logic in the FPGA fabric cannot disable the HPS JTAG. 0x1 JTAG enable interface is enabled. Logic in the FPGA fabric can disable the HPS JTAG.	RW	0x1
0	rstreqintf	Used to disable the reset request interface. This interface allows logic in the FPGA fabric to request HPS resets. This field disables the following reset request signals from the FPGA fabric to HPS:[list] [*]f2h_cold_rst_req_n - Triggers a cold reset of the HPS[*]f2h_warm_rst_req_n - Triggers a warm reset of the HPS[*]f2h_dbg_rst_req_n - Triggers a debug reset of the HPS[/list] **Value** **Description** 0x0 Reset request interface is disabled. Logic in the FPGA fabric cannot reset the HPS. 0x1 Reset request interface is enabled. Logic in the FPGA fabric can reset the HPS.	RW	0x1

module

Used to disable signals from the FPGA fabric to individual HPS modules.

Bit	Name	Description	Access	Reset
0	fpgajtagen	Controls whether FPGA JTAG pins or Scan Manager drives JTAG signals to the FPGA. Only reset by a cold reset (ignores warm reset). **Value** **Description** 0x0 FPGA JTAG pins drive JTAG signals to FPGA 0x1 Scan Manager drives JTAG signals to FPGA	RW	0x0

Freeze Control Group Register Descriptions

Registers used to generate HPS IO freeze signals. All registers are only reset by a cold reset (ignore warm reset).

Offset: 0x40

vioctrl on page 5-36
Used to drive freeze signals to HPS VIO banks. The register array index corresponds to the freeze channel. Freeze channel 0 provides freeze signals to VIO bank 0 and 1. Freeze channel 1 provides freeze signals to VIO bank 2 and 3. Only drives freeze signals when SRC.VIO1 is set to SW. Freeze channel 2 provides freeze signals to VIO bank 4. All fields are only reset by a cold reset (ignore warm reset). The following equation determines when the weak pullup resistor is enabled: enabled = ~wkpullup | (CFF & cfg & tristate) where CFF is the value of weak pullup as set by IO configuration

hioctrl on page 5-37
Used to drive freeze signals to HPS HIO bank (DDR SDRAM). All fields are only reset by a cold reset (ignore warm reset). The following equation determines when the weak pullup resistor is enabled: enabled = ~wkpullup | (CFF & cfg & tristate) where CFF is the value of weak pullup as set by IO configuration

src on page 5-39
Contains register field to choose between software state machine (vioctrl array index [1] register) or hardware state machine in the Freeze Controller as the freeze signal source for VIO channel 1. All fields are only reset by a cold reset (ignore warm reset).

hwctrl on page 5-40
Activate freeze or thaw operations on VIO channel 1 (HPS IO bank 2 and bank 3) and monitor for completeness and the current state. These fields interact with the hardware state machine in the Freeze Controller. These fields can be accessed independent of the value of SRC1.VIO1 although they only have an effect on the VIO channel 1 freeze signals when SRC1.VIO1 is setup to have the hardware state machine be the freeze signal source. All fields are only reset by a cold reset (ignore warm reset).

vioctrl

Used to drive freeze signals to HPS VIO banks. The register array index corresponds to the freeze channel. Freeze channel 0 provides freeze signals to VIO bank 0 and 1. Freeze channel 1 provides freeze signals to VIO bank 2 and 3. Only drives freeze signals when SRC.VIO1 is set to SW. Freeze channel 2 provides freeze signals to VIO bank 4. All fields are only reset by a cold reset (ignore warm reset). The following equation determines when the weak pullup resistor is enabled: enabled = ~wkpullup | (CFF & cfg & tristate) where CFF is the value of weak pullup as set by IO configuration

Boot ROM Code Register Group Register Descriptions

Registers used by the Boot ROM code. All fields are only reset by a cold reset (ignore warm reset).

Offset: 0xc0

ctrl on page 5-51
Contains information used to control Boot ROM code.

cpu1startaddr on page 5-52
When CPU1 is released from reset and the Boot ROM is located at the CPU1 reset exception address (the typical case), the Boot ROM reset handler code reads the address stored in this register and jumps it to hand off execution to user software.

initswstate on page 5-53
The preloader software (loaded by the Boot ROM) writes the magic value 0x49535756 (ISWV in ASCII) to this register when it has reached a valid state.

initswlastld on page 5-53
Contains the index of the last preloader software image loaded by the Boot ROM from the boot device.

bootromswstate on page 5-54
32-bits general purpose register used by the Boot ROM code. Actual usage is defined in the Boot ROM source code.

Warm Boot from On-Chip RAM Group Register Descriptions on page 5-55
Registers used by the Boot ROM code to support booting from the On-chip RAM on a warm reset. All these registers must be written by user software before a warm reset occurs to make use of this feature.

ctrl

Contains information used to control Boot ROM code.

Warm Boot from On-Chip RAM Group Register Descriptions

Registers used by the Boot ROM code to support booting from the On-chip RAM on a warm reset. All these registers must be written by user software before a warm reset occurs to make use of this feature.

Offset: `0x20`

enable on page 5-55
Enables or disables the warm reset from On-chip RAM feature.

datastart on page 5-56
Offset into On-chip RAM of the start of the region for CRC validation

length on page 5-56
Length of region in On-chip RAM for CRC validation.

execution on page 5-57
Offset into On-chip RAM to enter to on a warm boot.

crc on page 5-58
Length of region in On-chip RAM for CRC validation.

enable

Enables or disables the warm reset from On-chip RAM feature.

Module Instance	Base Address	Register Address
sysmgr	0xFFD08000	0xFFD080E0

Offset: `0xE0`

Access: `RW`

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
magic RW 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
magic RW 0x0															

enable Fields

Bit	Name	Description	Access	Reset
31:0	magic	Controls whether Boot ROM will attempt to boot from the contents of the On-chip RAM on a warm reset. When this feature is enabled, the Boot ROM code will not configure boot IOs, the pin mux, or clocks. Note that the enable value is a 32-bit magic value (provided by the enum). **Value** — **Description** 0x0 — Boot ROM code will not attempt to boot from On-chip RAM on a warm reset 0xae9efebc — Boot ROM code will attempt to boot from On-chip RAM on a warm reset	RW	0x0

datastart

Offset into On-chip RAM of the start of the region for CRC validation

Module Instance	Base Address	Register Address
sysmgr	0xFFD08000	0xFFD080E4

Offset: 0xE4

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
offset RW 0x0															

datastart Fields

Bit	Name	Description	Access	Reset
15:0	offset	Contains the byte offset into the On-chip RAM of the start of the On-chip RAM region for the warm boot CRC validation. The offset must be an integer multiple of 4 (i.e. aligned to a word). The Boot ROM code will set the top 16 bits to 0xFFFF and clear the bottom 2 bits.	RW	0x0

length

Length of region in On-chip RAM for CRC validation.

Module Instance	Base Address	Register Address
sysmgr	0xFFD08000	0xFFD080E8

Offset: 0xE8

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
size RW 0x0															

length Fields

Bit	Name	Description	Access	Reset
15:0	size	Contains the length (in bytes) of the region in the On-chip RAM for the warm boot CRC validation. If the length is 0, the Boot ROM won't perform CRC calculation and CRC check to avoid overhead caused by CRC validation. If the START + LENGTH exceeds the maximum offset into the On-chip RAM, the Boot ROM won't boot from the On-chip RAM. The length must be an integer multiple of 4. The Boot ROM code will clear the top 16 bits and the bottom 2 bits.	RW	0x0

execution

Offset into On-chip RAM to enter to on a warm boot.

Module Instance	Base Address	Register Address
sysmgr	0xFFD08000	0xFFD080EC

Offset: 0xEC

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
offset RW 0x0															

execution Fields

Bit	Name	Description	Access	Reset
15:0	offset	Contains the byte offset into the On-chip RAM that the Boot ROM will jump to if the CRC validation succeeds. The Boot ROM code will set the top 16 bits to 0xFFFF.	RW	0x0

crc

Length of region in On-chip RAM for CRC validation.

Module Instance	Base Address	Register Address
sysmgr	0xFFD08000	0xFFD080F0

Offset: 0xF0

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
expected RW 0xE763552A															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
expected RW 0xE763552A															

crc Fields

Bit	Name	Description	Access	Reset
31:0	expected	Contains the expected CRC of the region in the On-chip RAM.The Boot ROM code calculates the actual CRC for all bytes in the region specified by the DATA START an LENGTH registers. The contents of the EXECUTION register (after it has been read and modified by the Boot ROM code) is also included in the CRC calculation. The contents of the EXECUTION register is added to the CRC accumulator a byte at a time starting with the least significant byte. If the actual CRC doesn't match the expected CRC value in this register, the Boot ROM won't boot from the On-chip RAM. The CRC is a standard CRC32 with the polynomial: x^32 + x^26 + x^23 + x^22 + x^16 + x^12 + x^11 + x^10 + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1 There is no reflection of the bits and the initial value of the remainder is 0xFFFFFFFF and the final value is exclusive ORed with 0xFFFFFFFF.	RW	0xE763552A

Boot ROM Hardware Register Group Register Descriptions

Registers used by the Boot ROM hardware, not the code within it.

Offset: `0x100`

ctrl on page 5-59
Controls behavior of Boot ROM hardware. All fields are only reset by a cold reset (ignore warm reset).

ctrl

Controls behavior of Boot ROM hardware. All fields are only reset by a cold reset (ignore warm reset).

ECC Management Register Group Register Descriptions

ECC error status and control for all ECC-protected HPS RAM blocks.

Offset: 0x140

l2 on page 5-68
This register is used to enable ECC on the L2 Data RAM. ECC errors can be injected into the write path using bits in this register. This register contains interrupt status of the ECC single/double bit error. Only reset by a cold reset (ignores warm reset).

ocram on page 5-69
This register is used to enable ECC on the On-chip RAM. ECC errors can be injected into the write path using bits in this register. This register contains interrupt status of the ECC single/double bit error. Only reset by a cold reset (ignores warm reset).

usb0 on page 5-70
This register is used to enable ECC on the USB0 RAM. ECC errors can be injected into the write path using bits in this register. This register contains interrupt status of the ECC single/double bit error. Only reset by a cold reset (ignores warm reset).

usb1 on page 5-71
This register is used to enable ECC on the USB1 RAM. ECC errors can be injected into the write path using bits in this register. This register contains interrupt status of the ECC single/double bit error. Only reset by a cold reset (ignores warm reset).

emac0 on page 5-72
This register is used to enable ECC on the EMAC0 RAM. ECC errors can be injected into the write path using bits in this register. This register contains interrupt status of the ECC single/double bit error. Only reset by a cold reset (ignores warm reset).

emac1 on page 5-73
This register is used to enable ECC on the EMAC1 RAM. ECC errors can be injected into the write path using bits in this register. This register contains interrupt status of the ECC single/double bit error. Only reset by a cold reset (ignores warm reset).

dma on page 5-75
This register is used to enable ECC on the DMA RAM. ECC errors can be injected into the write path using bits in this register. This register contains interrupt status of the ECC single/double bit error. Only reset by a cold reset (ignores warm reset).

can0 on page 5-76
This register is used to enable ECC on the CAN0 RAM. ECC errors can be injected into the write path using bits in this register. This register contains interrupt status of the ECC single/double bit error. Only reset by a cold reset (ignores warm reset).

can1 on page 5-77
This register is used to enable ECC on the CAN1 RAM. ECC errors can be injected into the write path using bits in this register. This register contains interrupt status of the ECC single/double bit error. Only reset by a cold reset (ignores warm reset).

nand on page 5-78
This register is used to enable ECC on the NAND RAM. ECC errors can be injected into the write path using bits in this register. This register contains interrupt status of the ECC single/double bit error. Only reset by a cold reset (ignores warm reset).

qspi on page 5-80
This register is used to enable ECC on the QSPI RAM. ECC errors can be injected into the write path using bits in this register. This register contains interrupt status of the ECC single/double bit error. Only reset by a cold reset (ignores warm reset).

sdmmc on page 5-81
This register is used to enable ECC on the SDMMC RAM.ECC errors can be injected into the write path using bits in this register. Only reset by a cold reset (ignores warm reset).

l2

This register is used to enable ECC on the L2 Data RAM. ECC errors can be injected into the write path using bits in this register. This register contains interrupt status of the ECC single/double bit error. Only reset by a cold reset (ignores warm reset).

Pin Mux Control Group Register Descriptions

Controls Pin Mux selections NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

Offset: 0x400

EMACIO0 on page 5-102
This register is used to control the peripherals connected to emac0_tx_clk Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

EMACIO1 on page 5-102
This register is used to control the peripherals connected to emac0_tx_d0 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

EMACIO2 on page 5-103
This register is used to control the peripherals connected to emac0_tx_d1 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

FLASHIO5 on page 5-117
This register is used to control the peripherals connected to sdmmc_d5 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

FLASHIO6 on page 5-118
This register is used to control the peripherals connected to sdmmc_d6 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

FLASHIO7 on page 5-118
This register is used to control the peripherals connected to sdmmc_d7 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

FLASHIO8 on page 5-119
This register is used to control the peripherals connected to sdmmc_clk_in Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

FLASHIO9 on page 5-120
This register is used to control the peripherals connected to sdmmc_clk Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

FLASHIO10 on page 5-120
This register is used to control the peripherals connected to sdmmc_d2 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

FLASHIO11 on page 5-121
This register is used to control the peripherals connected to sdmmc_d3 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GENERALIO0 on page 5-121
This register is used to control the peripherals connected to trace_clk Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GENERALIO1 on page 5-122
This register is used to control the peripherals connected to trace_d0 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GENERALIO2 on page 5-123
This register is used to control the peripherals connected to trace_d1 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GENERALIO3 on page 5-123
This register is used to control the peripherals connected to trace_d2 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GENERALIO4 on page 5-124
This register is used to control the peripherals connected to trace_d3 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GENERALIO5 on page 5-124
This register is used to control the peripherals connected to trace_d4 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GENERALIO6 on page 5-125
This register is used to control the peripherals connected to trace_d5 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GENERALIO7 on page 5-126
This register is used to control the peripherals connected to trace_d6 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GENERALIO8 on page 5-126
This register is used to control the peripherals connected to trace_d7 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GENERALIO9 on page 5-127
This register is used to control the peripherals connected to spim0_clk Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GENERALIO10 on page 5-127
This register is used to control the peripherals connected to spim0_mosi Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GENERALIO11 on page 5-128
This register is used to control the peripherals connected to spim0_miso Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GENERALIO12 on page 5-129
This register is used to control the peripherals connected to spim0_ss0 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GENERALIO13 on page 5-129
This register is used to control the peripherals connected to uart0_rx Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GENERALIO14 on page 5-130
This register is used to control the peripherals connected to uart0_tx Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GENERALIO15 on page 5-130
This register is used to control the peripherals connected to i2c0_sda Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GENERALIO16 on page 5-131
This register is used to control the peripherals connected to i2c0_scl Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GENERALIO17 on page 5-132
This register is used to control the peripherals connected to can0_rx Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GENERALIO18 on page 5-132
This register is used to control the peripherals connected to can0_tx Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GENERALIO19 on page 5-133
This register is used to control the peripherals connected to spis1_clk Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GENERALIO20 on page 5-133
This register is used to control the peripherals connected to spis1_mosi Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GENERALIO21 on page 5-134
This register is used to control the peripherals connected to spis1_miso Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GENERALIO22 on page 5-135
This register is used to control the peripherals connected to spis1_ss0 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GENERALIO23 on page 5-135
This register is used to control the peripherals connected to uart1_rx Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GENERALIO24 on page 5-136
This register is used to control the peripherals connected to uart1_tx Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GENERALIO25 on page 5-136
This register is used to control the peripherals connected to i2c1_sda Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

MIXED1IO5 on page 5-144
This register is used to control the peripherals connected to nand_dq0 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

MIXED1IO6 on page 5-144
This register is used to control the peripherals connected to nand_dq1 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

MIXED1IO7 on page 5-145
This register is used to control the peripherals connected to nand_dq2 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

MIXED1IO8 on page 5-145
This register is used to control the peripherals connected to nand_dq3 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

MIXED1IO9 on page 5-146
This register is used to control the peripherals connected to nand_dq4 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

MIXED1IO10 on page 5-147
This register is used to control the peripherals connected to nand_dq5 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

MIXED1IO11 on page 5-147
This register is used to control the peripherals connected to nand_dq6 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

MIXED1IO12 on page 5-148
This register is used to control the peripherals connected to nand_dq7 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

MIXED1IO13 on page 5-148
This register is used to control the peripherals connected to nand_wp Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

MIXED1IO14 on page 5-149
This register is used to control the peripherals connected to nand_we Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

MIXED1IO15 on page 5-150
This register is used to control the peripherals connected to qspi_io0 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

MIXED2IO5 on page 5-157
This register is used to control the peripherals connected to emac1_rx_ctl Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

MIXED2IO6 on page 5-157
This register is used to control the peripherals connected to emac1_rx_d2 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

MIXED2IO7 on page 5-158
This register is used to control the peripherals connected to emac1_rx_d3 Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLINMUX48 on page 5-159
Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 48. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLINMUX49 on page 5-159
Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 49. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLINMUX50 on page 5-160
Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 50. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLINMUX51 on page 5-160
Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 51. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLINMUX52 on page 5-161
Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 52. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLINMUX53 on page 5-161
Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 53. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLINMUX54 on page 5-162
Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 54. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLINMUX55 on page 5-163
Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 55. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLINMUX56 on page 5-163
Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 56. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLINMUX57 on page 5-164
Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 57. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLINMUX58 on page 5-164
Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 58. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLINMUX59 on page 5-165
Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 59. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLINMUX60 on page 5-165
Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 60. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLINMUX61 on page 5-166
Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 61. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLINMUX62 on page 5-167
Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 62. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLINMUX63 on page 5-167
Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 63. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLINMUX64 on page 5-168
Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 64. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLINMUX65 on page 5-168
Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 65. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLINMUX66 on page 5-169
Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 66. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLINMUX67 on page 5-169
Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 67. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLINMUX68 on page 5-170
Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 68. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLINMUX69 on page 5-171
Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 69. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLINMUX70 on page 5-171
Some GPIO/LoanIO inputs can be driven by multiple pins. This register selects the input signal for GPIO/LoanIO 70. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX0 on page 5-172
Selection between GPIO and LoanIO output and output enable for GPIO0 and LoanIO0. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX1 on page 5-172
Selection between GPIO and LoanIO output and output enable for GPIO1 and LoanIO1. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX2 on page 5-173
Selection between GPIO and LoanIO output and output enable for GPIO2 and LoanIO2. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX3 on page 5-174
Selection between GPIO and LoanIO output and output enable for GPIO3 and LoanIO3. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX4 on page 5-174
Selection between GPIO and LoanIO output and output enable for GPIO4 and LoanIO4. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX5 on page 5-175
Selection between GPIO and LoanIO output and output enable for GPIO5 and LoanIO5. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX6 on page 5-175
Selection between GPIO and LoanIO output and output enable for GPIO6 and LoanIO6. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX7 on page 5-176
Selection between GPIO and LoanIO output and output enable for GPIO7 and LoanIO7. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX8 on page 5-177
Selection between GPIO and LoanIO output and output enable for GPIO8 and LoanIO8. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX9 on page 5-177
Selection between GPIO and LoanIO output and output enable for GPIO9 and LoanIO9. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX10 on page 5-178
Selection between GPIO and LoanIO output and output enable for GPIO10 and LoanIO10. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX11 on page 5-178
Selection between GPIO and LoanIO output and output enable for GPIO11 and LoanIO11. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX12 on page 5-179
Selection between GPIO and LoanIO output and output enable for GPIO12 and LoanIO12. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX13 on page 5-180
Selection between GPIO and LoanIO output and output enable for GPIO13 and LoanIO13. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX14 on page 5-180
Selection between GPIO and LoanIO output and output enable for GPIO14 and LoanIO14. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX15 on page 5-181
Selection between GPIO and LoanIO output and output enable for GPIO15 and LoanIO15. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX16 on page 5-181
Selection between GPIO and LoanIO output and output enable for GPIO16 and LoanIO16. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX17 on page 5-182
Selection between GPIO and LoanIO output and output enable for GPIO17 and LoanIO17. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX18 on page 5-183
Selection between GPIO and LoanIO output and output enable for GPIO18 and LoanIO18. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX19 on page 5-183
Selection between GPIO and LoanIO output and output enable for GPIO19 and LoanIO19. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX20 on page 5-184
Selection between GPIO and LoanIO output and output enable for GPIO20 and LoanIO20. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX21 on page 5-184
Selection between GPIO and LoanIO output and output enable for GPIO21 and LoanIO21. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX22 on page 5-185
Selection between GPIO and LoanIO output and output enable for GPIO22 and LoanIO22. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX23 on page 5-186
Selection between GPIO and LoanIO output and output enable for GPIO23 and LoanIO23. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX24 on page 5-186
Selection between GPIO and LoanIO output and output enable for GPIO24 and LoanIO24. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX25 on page 5-187
Selection between GPIO and LoanIO output and output enable for GPIO25 and LoanIO25. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX26 on page 5-187
Selection between GPIO and LoanIO output and output enable for GPIO26 and LoanIO26. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX27 on page 5-188
Selection between GPIO and LoanIO output and output enable for GPIO27 and LoanIO27. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX28 on page 5-189
Selection between GPIO and LoanIO output and output enable for GPIO28 and LoanIO28. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX29 on page 5-189
Selection between GPIO and LoanIO output and output enable for GPIO29 and LoanIO29. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX30 on page 5-190
Selection between GPIO and LoanIO output and output enable for GPIO30 and LoanIO30. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX31 on page 5-190
Selection between GPIO and LoanIO output and output enable for GPIO31 and LoanIO31. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX32 on page 5-191
Selection between GPIO and LoanIO output and output enable for GPIO32 and LoanIO32. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX33 on page 5-192
Selection between GPIO and LoanIO output and output enable for GPIO33 and LoanIO33. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX34 on page 5-192
Selection between GPIO and LoanIO output and output enable for GPIO34 and LoanIO34. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX35 on page 5-193
Selection between GPIO and LoanIO output and output enable for GPIO35 and LoanIO35. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX36 on page 5-193
Selection between GPIO and LoanIO output and output enable for GPIO36 and LoanIO36. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX37 on page 5-194
Selection between GPIO and LoanIO output and output enable for GPIO37 and LoanIO37. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX38 on page 5-195
Selection between GPIO and LoanIO output and output enable for GPIO38 and LoanIO38. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX39 on page 5-195
Selection between GPIO and LoanIO output and output enable for GPIO39 and LoanIO39. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX40 on page 5-196
Selection between GPIO and LoanIO output and output enable for GPIO40 and LoanIO40. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX41 on page 5-196
Selection between GPIO and LoanIO output and output enable for GPIO41 and LoanIO41. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX42 on page 5-197
Selection between GPIO and LoanIO output and output enable for GPIO42 and LoanIO42. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX43 on page 5-198
Selection between GPIO and LoanIO output and output enable for GPIO43 and LoanIO43. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX44 on page 5-198
Selection between GPIO and LoanIO output and output enable for GPIO44 and LoanIO44. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX45 on page 5-199
Selection between GPIO and LoanIO output and output enable for GPIO45 and LoanIO45. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX46 on page 5-199
Selection between GPIO and LoanIO output and output enable for GPIO46 and LoanIO46. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX47 on page 5-200
Selection between GPIO and LoanIO output and output enable for GPIO47 and LoanIO47. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX48 on page 5-201
Selection between GPIO and LoanIO output and output enable for GPIO48 and LoanIO48. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX49 on page 5-201
Selection between GPIO and LoanIO output and output enable for GPIO49 and LoanIO49. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX50 on page 5-202
Selection between GPIO and LoanIO output and output enable for GPIO50 and LoanIO50. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX51 on page 5-202
Selection between GPIO and LoanIO output and output enable for GPIO51 and LoanIO51. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX52 on page 5-203
Selection between GPIO and LoanIO output and output enable for GPIO52 and LoanIO52. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX53 on page 5-204
Selection between GPIO and LoanIO output and output enable for GPIO53 and LoanIO53. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX54 on page 5-204
Selection between GPIO and LoanIO output and output enable for GPIO54 and LoanIO54. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX55 on page 5-205
Selection between GPIO and LoanIO output and output enable for GPIO55 and LoanIO55. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX56 on page 5-205
Selection between GPIO and LoanIO output and output enable for GPIO56 and LoanIO56. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX57 on page 5-206
Selection between GPIO and LoanIO output and output enable for GPIO57 and LoanIO57. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX58 on page 5-207
Selection between GPIO and LoanIO output and output enable for GPIO58 and LoanIO58. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX59 on page 5-207
Selection between GPIO and LoanIO output and output enable for GPIO59 and LoanIO59. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX60 on page 5-208
Selection between GPIO and LoanIO output and output enable for GPIO60 and LoanIO60. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX61 on page 5-208
Selection between GPIO and LoanIO output and output enable for GPIO61 and LoanIO61. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX62 on page 5-209
Selection between GPIO and LoanIO output and output enable for GPIO62 and LoanIO62. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX63 on page 5-210
Selection between GPIO and LoanIO output and output enable for GPIO63 and LoanIO63. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX64 on page 5-210
Selection between GPIO and LoanIO output and output enable for GPIO64 and LoanIO64. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX65 on page 5-211
Selection between GPIO and LoanIO output and output enable for GPIO65 and LoanIO65. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX66 on page 5-211
Selection between GPIO and LoanIO output and output enable for GPIO66 and LoanIO66. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX67 on page 5-212
Selection between GPIO and LoanIO output and output enable for GPIO67 and LoanIO67. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX68 on page 5-213
Selection between GPIO and LoanIO output and output enable for GPIO68 and LoanIO68. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX69 on page 5-213
Selection between GPIO and LoanIO output and output enable for GPIO69 and LoanIO69. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

GPLMUX70 on page 5-214
Selection between GPIO and LoanIO output and output enable for GPIO70 and LoanIO70. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

NANDUSEFPGA on page 5-214
Selection between HPS Pins and FPGA Interface for NAND signals. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

RGMII1USEFPGA on page 5-215
Selection between HPS Pins and FPGA Interface for RGMII1 signals. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

I2C0USEFPGA on page 5-215
Selection between HPS Pins and FPGA Interface for I2C0 signals. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

RGMII0USEFPGA on page 5-216
Selection between HPS Pins and FPGA Interface for RGMII0 signals. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

I2C3USEFPGA on page 5-216
Selection between HPS Pins and FPGA Interface for I2C3 signals. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

I2C2USEFPGA on page 5-217
Selection between HPS Pins and FPGA Interface for I2C2 signals. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

I2C1USEFPGA on page 5-218
Selection between HPS Pins and FPGA Interface for I2C1 signals. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

SPIM1USEFPGA on page 5-218
Selection between HPS Pins and FPGA Interface for SPIM1 signals. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

SPIM0USEFPGA on page 5-219
Selection between HPS Pins and FPGA Interface for SPIM0 signals. Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

EMACIO0

This register is used to control the peripherals connected to emac0_tx_clk Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

0	sel	Select source for GPIO/LoanIO 70. 0 : Source for GPIO/LoanIO 70 is GENERALIO22. 1 : Source for GPIO/LoanIO 70 is GENERALIO31.	RW	0x0

GPLMUX0

Selection between GPIO and LoanIO output and output enable for GPIO0 and LoanIO0. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

Module Instance	Base Address	Register Address

GPLMUX48

Selection between GPIO and LoanIO output and output enable for GPIO48 and LoanIO48. These signals drive the Pin Mux. The Pin Mux must be configured to use GPIO/LoanIO in addition to these settings Only reset by a cold reset (ignores warm reset). NOTE: These registers should not be modified after IO configuration.There is no support for dynamically changing the Pin Mux selections.

Scan Manager 6

2014.12.15

av_5v4

The scan manager is used to configure and manage the HPS I/O pins, and communicate with the FPGA JTAG test access port (TAP) controller. The scan manager drives the HPS I/O scan chains to configure the I/O bank properties before the pins are used by the peripherals in HPS. The scan manager can also optionally communicate with the FPGA JTAG TAP controller to send commands for purposes such as managing cyclic redundancy check (CRC) errors detected by the FPGA control block. When the scan manager communicates with the FPGA JTAG TAP controller, input on the FPGA JTAG pins is ignored.

The scan manager contains an ARM® JTAG Access Port (JTAG-AP). The JTAG-AP implements a multiple scan-chain JTAG master interface. One scan chain connects to the FPGA JTAG and uses the standard JTAG signals. Four other scan chains connect to the HPS I/O banks, using the JTAG clock and data outputs as a parallel-to-serial converter.

Related Information

http://infocenter.arm.com/

For more information about the ARM JTAG-AP, refer to the *DAP Components* chapter of the *CoreSight SoC Technical Reference Manual* , which you can download from the ARM Infocenter website.

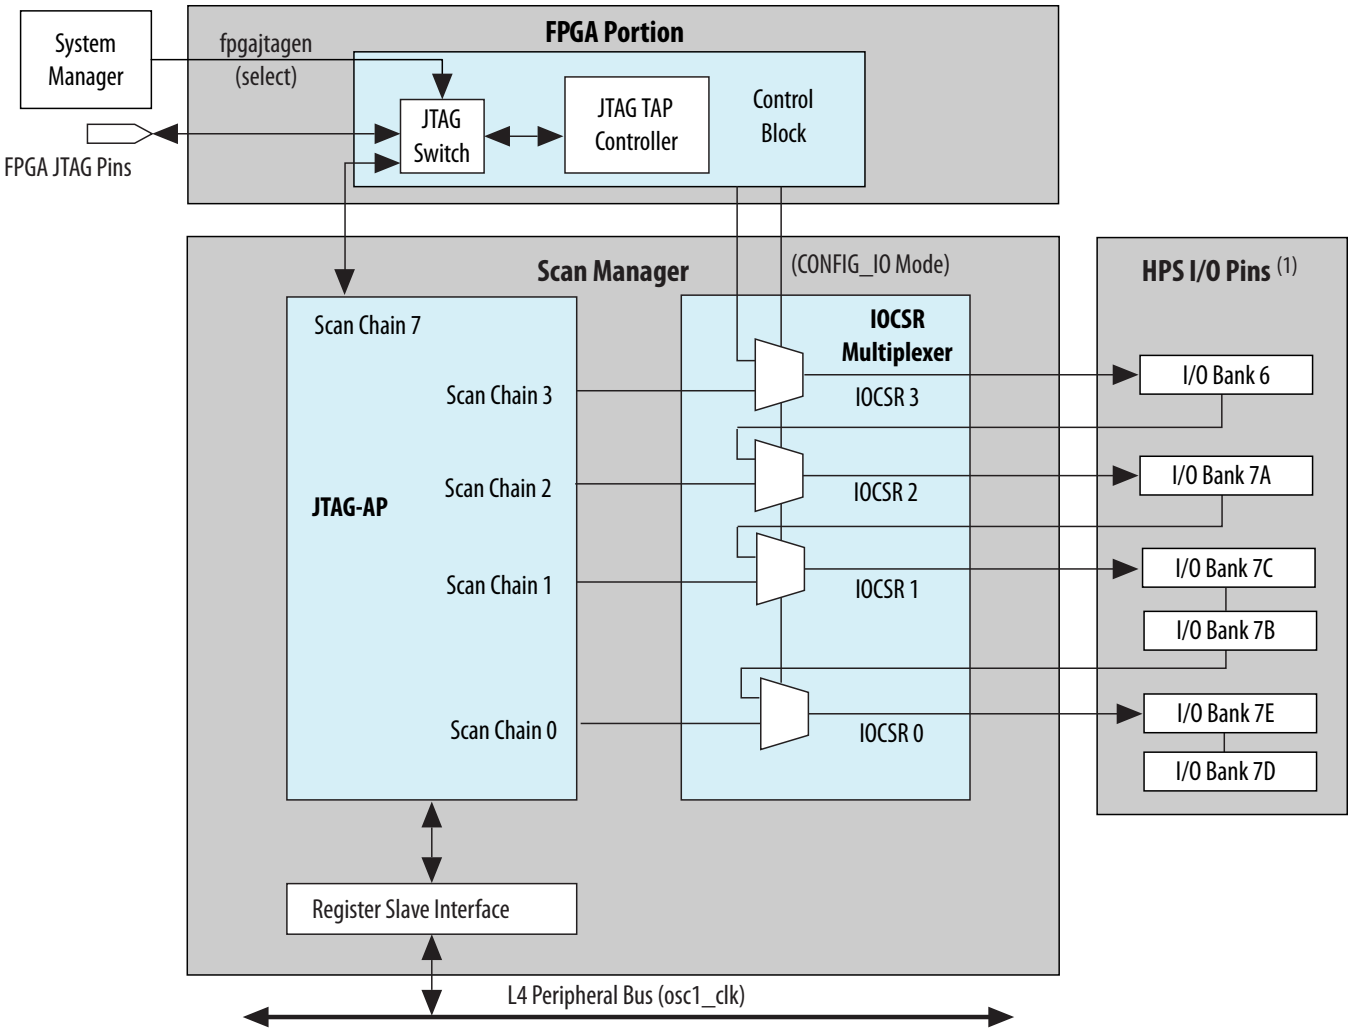
Features of the Scan Manager

- Drives all the I/O scan chains for HPS I/O banks
- Allows the HPS to access the FPGA JTAG TAP controller

Scan Manager Block Diagram and System Integration

Figure 6-1: Scan Manager Block Diagram

(1) Not all devices contain all the banks depicted.



The processor accesses the scan manager through the register slave interface connected to the level 4 (L4) peripheral bus.

ARM JTAG-AP Signal Use in the Scan Manager

The following table describes how the ARM JTAG-AP signals are connected in the scan manager. These signals are internal to the scan manager, are provided here for reference only, and are not shown in the preceding figure. The signal, register, and field names listed in the table match the names used in the *ARM Debug Interface v5 Architecture Specification*.

Signal	Direction	Implementation
SRSTCONNECTED[7:0]	Input	Tied to 0. The read-only SRSTCONNECTED field in the CSW register always reads as 0.
PORTCONNECTED[7:0]	Input	Tied to 0x8F, which connects only ports 0-3 and 7. The read-only PORTCONNECTED field in the CSW register reads as 1 when the PORTSEL register is written with a value that enables one of the connected ports, and reads as 0 otherwise.
PORTENABLED[7:0]	Input	Tied to 0x8F, so all connected ports are always considered powered on. The ARM JTAG AP PSTA register is not supported. Software does not need to monitor the status of ports 0-3 because they are always on. For port 7, software can read the mode field of the stat register in the FPGA manager to determine the FPGA power status.
nSRSTOUT[7:0]	Output	Not connected. Writing to the SRST_OUT field of the CSW register has no effect.
nTRST*[7:0]	Output	nTRST*[7] is connected to the FPGA JTAG TAP controller and nTRST*[6:0] are not connected. Writing to the TRST_OUT field of the CSW register (the trst bit of the stat register in the scan manager) has an effect only when port 7 is enabled by software. For details, refer to *"Communicating with the JTAG TAP Controller"*.

  For detailed information about the ARM JTAG-AP CSW , PORTSEL , and PSTA registers, refer to the *DAP Components* chapter of the *CoreSight SoC Technical Reference Manual* , which you can download from the ARM Infocenter website.

ARM JTAG-AP Scan Chains

The ARM JTAG-AP supports up to eight scan chains. The scan manager uses only scan chains 0, 1, 2, 3, and 7.

Scan chain 7 of the JTAG-AP connects to FPGA JTAG TAP controller. When the system manager undergoes a cold reset, this connection is disabled and the FPGA JTAG pins are connected to the FPGA JTAG TAP controller. You can configure the system manager to enable the connection, which allows software running on the HPS to communicate with the FPGA JTAG TAP controller. In this case, software

can send JTAG commands (such as the SHIFT_EDERROR_REG JTAG instruction) to the FPGA JTAG and get responses to determine details about CRC errors detected by the control block when the FPGA fabric is in user mode. Through the FPGA manager, software can determine that a CRC error was detected. For more information about the TAP controller, refer to the *Communicating with the JTAG TAP Controller* section of this chapter.

Scan chains 0 to 3 of the JTAG-AP connect to the configuration information in the HPS I/O scan chain banks through the I/O configuration shift register (IOCSR) multiplexer. For more information, refer to the *Configuring HPS I/O Scan Chains* section of this chapter.

Note: The I/O scan chains do not use the JTAG protocol. The scan manager uses the JTAG-AP as a parallel-to-serial converter for the I/O scan chains. The I/O scan chains are connected only to the serial output data (TDI JTAG signal) and serial clock (TCK JTAG signal).

The HPS I/O pins are divided into six banks. Each I/O bank is either a vertical (VIO) or horizontal (HIO) I/O, based on its location on the die.

Table 6-1: Bank Usage of IOCSR Scan Chains

The following table shows the mapping of the IOCSR scan chains to the I/O banks.

IOCSR Scan Chain	Bank Type	HPS I/O Bank	Usage
0	VIO	I/O bank 7D and I/O bank 7E	EMAC
1	VIO	I/O bank 7B and I/O bank 7C	SD/MMC, NAND, and quad SPI
2	VIO	I/O bank 7A	Trace, SPI, UART, and I^2C
3	HIO	I/O bank 6	SDRAM DDR

When the FPGA JTAG TAP controller is in CONFIG_IO mode, the controller can override the scan manager JTAG-AP and configure the HPS I/O pins. For more information, refer to the *Configuring HPS I/O Scan Chains* section of this chapter.

Note: CONFIG_IO mode is commonly used to configure the I/O pin properties prior to performing boundary scan testing.

Note: The HPS JTAG pins does not support boundary scan tests (BST). To perform boundary scan testing on HPS I/O pins, use the FPGA JTAG.

Functional Description of the Scan Manager

The scan manager serves the following purposes:

- Configuring HPS I/O scan chains
- Communicating with the JTAG TAP controller

Configuring HPS I/O Scan Chains

The HPS I/O pins are configured through a series of scan chains.

I/O pin configuration involves such steps as setting the I/O standard and drive strength for each I/O bank. After a cold reset, all the I/O scan chains in the HPS must be configured prior to being used to communicate with external devices.

Software uses the scan manager to write configuration data to the scan chains. Separate I/O configuration data files for FPGA and HPS are generated by the Quartus® II software when the configuration image for the FPGA portion of the system-on-a-chip (SoC) device is assembled. The HPS configuration data is written to the scan manager by software.

Before configuring a specific I/O bank, the corresponding scan chain must be enabled by writing to the bits in the en register. The scan manager must not be active during this process. Software reads the active bit of the `stat` register to determine the scan manager state.

Alternatively, when the FPGA JTAG TAP controller receives the `CONFIG_IO` JTAG instruction, the control block enters `CONFIG_IO` mode. When the control block is in `CONFIG_IO` mode, the controller can override the scan manager JTAG-AP and configure the HPS I/O pins. The `CONFIG_IO` instruction configures all configurable I/O pins in the SoC device including the FPGA I/O pins and the HPS I/O pins. The FPGA and HPS portions of the device must both be powered on to execute the `CONFIG_IO` instruction. External logic connected to the FPGA JTAG pins sends the `CONFIG_IO` instruction, which provides I/O configuration data for all FPGA and HPS I/O pins. While `CONFIG_IO` mode is active, the HPS is held in cold reset to prevent software from potentially interfering with the I/O configuration.

Related Information

- **System Manager** on page 5-1
  The HPS I/O pins need to be frozen before configuring them. For more information, refer to the *System Manager* chapter.

Communicating with the JTAG TAP Controller

After the system manager undergoes a cold reset, access to the JTAG TAP controller in the FPGA control block is through the dedicated FPGA JTAG I/O pins. If necessary, you can configure your system to use the scan manager to provide the HPS processor access to the JTAG TAP controller, instead. This feature allows the processor to send JTAG instructions to the FPGA portion of the device.

To connect scan chain 7 between the scan manager and the FPGA JTAG TAP controller, the following features must be enabled:

- The scan chain for the FPGA JTAG TAP controller—To enable scan chain 7, set the `fpgajtag` field of the `en` register in the scan manager. For more information, refer to *"Scan Manager Address Map and Register Definitions"*.
- The FPGA JTAG logic source select—This source select determines whether the scan manager or the dedicated FPGA JTAG pins are connected to the FPGA JTAG TAP controller in the FPGA portion of the device. On system manager cold reset, the dedicated FPGA JTAG pins are selected. The source select is configured through the `fpgajtagen` bit of the `ctrl` register in the `scanmgrgrp` group of the system manager. The FPGA JTAG pins and scan manager connection to the TAP controller must both be inactive when switching between them. The mechanism to ensure both are inactive is user-defined.

Note: Before connecting or disconnecting the scan chain between the scan manager and the FPGA JTAG TAP controller, ensure that both the FPGA JTAG `TCK` and scan manager `TCK` signals are de-asserted. Altera recommends resetting the FPGA JTAG TAP controller using the scan manager's `nTRST` signal after the scan manager is connected to the controller.

JTAG-AP FIFO Buffer Access and Byte Command Protocol

The JTAG-AP contains FIFO buffers for byte commands and responses. The buffers are accessed through the `fifosinglebyte`, `fifodoublebyte`, `fifotriplebyte`, and `fifoquadbyte` registers. The JTAG-AP stalls processor access to the registers when the buffer does not contain enough data for read access, or when the buffer does not contain enough free space to accept data for write access.

Note: Software should read the `rfifocnt` and `wfifocnt` fields of the `stat` register to determine the buffer status before performing the access to avoid being stalled by the JTAG-AP.

JTAG-AP scan chains 0, 1, 2 and 3 are write-only ports connected to the HPS IOCSRs and JTAG-AP scan chain 7 is a read-write port connected to the FPGA JTAG TAP controller. The processor can send data to scan chains 0-3, and send and receive data from scan chain 7 by accessing the command and response FIFO buffers in the JTAG-AP.

Note: Attempting to access data at invalid or non-aligned offsets can produce unpredictable results that require a reset to recover.

The JTAG commands and `TDI` data must be sent to the JTAG-AP using an encoded byte protocol. Similarly, the `TDO` data received from JTAG-AP is encoded. All commands are 8 bits wide in the byte command protocol.

Table 6-2: JTAG-AP Byte Command Protocol

Bits of the Command Byte								Opcode
7	6	5	4	3	2	1	0	
0	Opcode Payload							TMS

Clocks

The scan manager is connected to the `spi_m_clk` clock generated by the clock manager.

The scan manager generates two clocks. One clock routes to the control block of the FPGA portion of the SoC device with a frequency of `spi_m_clk` / 6 and runs at a maximum of 33 MHz. The other clock routes to the HPS I/O scan chains with a frequency of `sp i_m_clk` / 2 and runs at a maximum frequency of 100 MHz.

Note: The `spi_m_clk` can potentially run faster than the scan manager supports so that SPI masters can support 60 Mbps rates. When the SPI master is running faster than what is supported by the scan manager, the scan manager cannot be used and must be held in reset.

Related Information

Clock Manager on page 2-1
For more information, including minimum and maximum clock frequencies, refer to the *Clock Manager* chapter.

Resets

The reset manager provides the `scan_manager_rst_n` reset signal to the scan manager for both cold and warm resets.

Because glitches can happen on the output clocks during a warm reset, the scan manager temporarily stops generation of the JTAG-AP and I/O configuration clocks. This action ensures that a warm reset does not cause output clock glitches.

Before asserting warm reset, the reset manager sends a request to the scan manager. The scan manager stops the output clock generation and acknowledges the reset manager. The reset manager then issues the warm reset. To enable this warm reset handshake, configure the `scanmgrhsen` bit of the reset manager `ctrl` register.

JTAG-AP Register Name Cross Reference Table

To clarify how Altera uses the JTAG-AP, the ARM registers are renamed in the SoC device. The following table cross references the ARM and Altera register names.

Table 6-3: JTAG-AP Register Names

Altera Register Name	ARM Register Name
`stat`	`CSW` (control/status word)
`en`	`PSEL`
`fifosinglebyte`	`BWFIFO1` for writes, `BRFIFO1` for reads
`fifodoublebyte`	`BWFIFO2` for writes, `BRFIFO2` for reads
`fifotriplebyte`	`BWFIFO3` for writes, `BRFIFO3` for reads
`fifoquadbyte`	`BWFIFO4` for writes, `BRFIFO4` for reads

Related Information

stat Fields

Bit	Name	Description	Access	Reset
31	active	Indicates if the Scan-Chain Engine is processing commands from the Command FIFO or not. The Scan-Chain Engine is only guaranteed to be inactive if both the ACTIVE and WFIFOCNT fields are zero. The name of this field in ARM documentation is SERACTV. **Value** **Description** 0x0 The Scan-Chain Engine may or may not be processing commands from the Command FIFO. The Scan-Chain Engine is only guaranteed to be inactive if both this ACTIVE field and the WFIFOCNT fields are both zero. 0x1 The Scan-Chain Engine is processing commands from the Command FIFO.	RO	0x0
30:28	wfifocnt	Command FIFO outstanding byte count. Returns the number of command bytes held in the Command FIFO that have yet to be processed by the Scan-Chain Engine.	RO	0x0
26:24	rfifocnt	Response FIFO outstanding byte count. Returns the number of bytes of response data available in the Response FIFO.	RO	0x0
3	ignore	Ignore this field. Its value is undefined (may be 0 or 1). The name of this field in ARM documentation is PORTCONNECTED.	RO	0x0
1	trst	Specifies the value of the nTRST signal driven to the FPGA JTAG only. The FPGA JTAG scan-chain must be enabled via the EN register to drive the value specified in this field. The nTRST signal is driven with the inverted value of this field.The nTRST signal is active low so, when this bit is set to 1, FPGA JTAG is reset. The name of this field in ARM documentation is TRST_OUT. **Value** **Description** 0x0 Don't reset FPGA JTAG. 0x1 Reset FPGA JTAG. Must have the FPGA JTAG scan-chain enabled in the EN register to take effect.	RW	0x0

en

This register is used to enable one of the 5 scan-chains (0-3 and 7). Only one scan-chain must be enabled at a time. A scan-chain is enabled by writing its corresponding enable field. Software must use the System Manager to put the corresponding I/O scan-chain into the frozen state before attempting to send I/O configuration data to the I/O scan-chain. Software must only write to this register when the Scan-Chain Engine is inactive.Writing this field at any other time has unpredictable results. This means that before writing to this field, software must read the STAT register and check that the ACTIVE and WFIFOCNT fields are both zero. The name of this register in ARM documentation is PSEL.

Module Instance	Base Address	Register Address

fifosinglebyte

Writes to the FIFO Single Byte Register write a single byte value to the command FIFO. If the command FIFO is full, the APB write operation is stalled until the command FIFO is not full. Reads from the Single Byte FIFO Register read a single byte value from the command FIFO. If the command FIFO is empty, the APB read operation is stalled until the command FIFO is not empty. See the ARM documentation for a description of the read and write values. The name of this register in ARM documentation is BWFIFO1 for writes and BRFIFO1 for reads.

Document Revision History

Table 6-4: Document Revision History

Date	Version	Changes
December 2014	2014.12.15	Maintenance release
June 2014	2014.06.30	• Add address map and register definitions • Remove erroneous reference to CAN controller
February 2014	2014.02.28	Update to "Scan Manager Block Diagram and System Integration" section
December 2013	2013.12.30	Minor formatting issues
November 2012	1.2	Added JTAG-AP descriptions.
May 2012	1.1	Added block diagram and system integration, functional description, and address map and register definitions sections.
January 2012	1.0	Initial release.

System Interconnect 7

2014.12.15

av_5v4 Subscribe Send Feedback

The components of the hard processor system (HPS) communicate with one another, and with other portions of the SoC device, through the system interconnect. The system interconnect consists of the following blocks:

- The main level 3 (L3) interconnect
- The level 4 (L4) buses

The system interconnect is implemented with the ARM CoreLink™ Network Interconnect (NIC-301). The NIC-301 provides a foundation for a high-performance HPS system interconnect based on the ARM Advanced Microcontroller Bus Architecture (AMBA®) Advanced eXtensible Interface (AXI™), Advanced High-Performance Bus (AHB™), and Advanced Peripheral Bus (APB™) protocols. The system interconnect implements a multilayer, nonblocking architecture that supports multiple simultaneous transactions between masters and slaves, including the Cortex-A9 microprocessor unit (MPU) subsystem. The system interconnect provides five independent L4 buses to access control and status registers (CSRs) of peripherals, managers, and memory controllers.

Related Information

http://infocenter.arm.com/

Additional information is available in the *AMBA Network Interconnect (NIC-301) Technical Reference Manual*, revision r2p3, which you can download from the ARM info center website.

Features of the System Interconnect

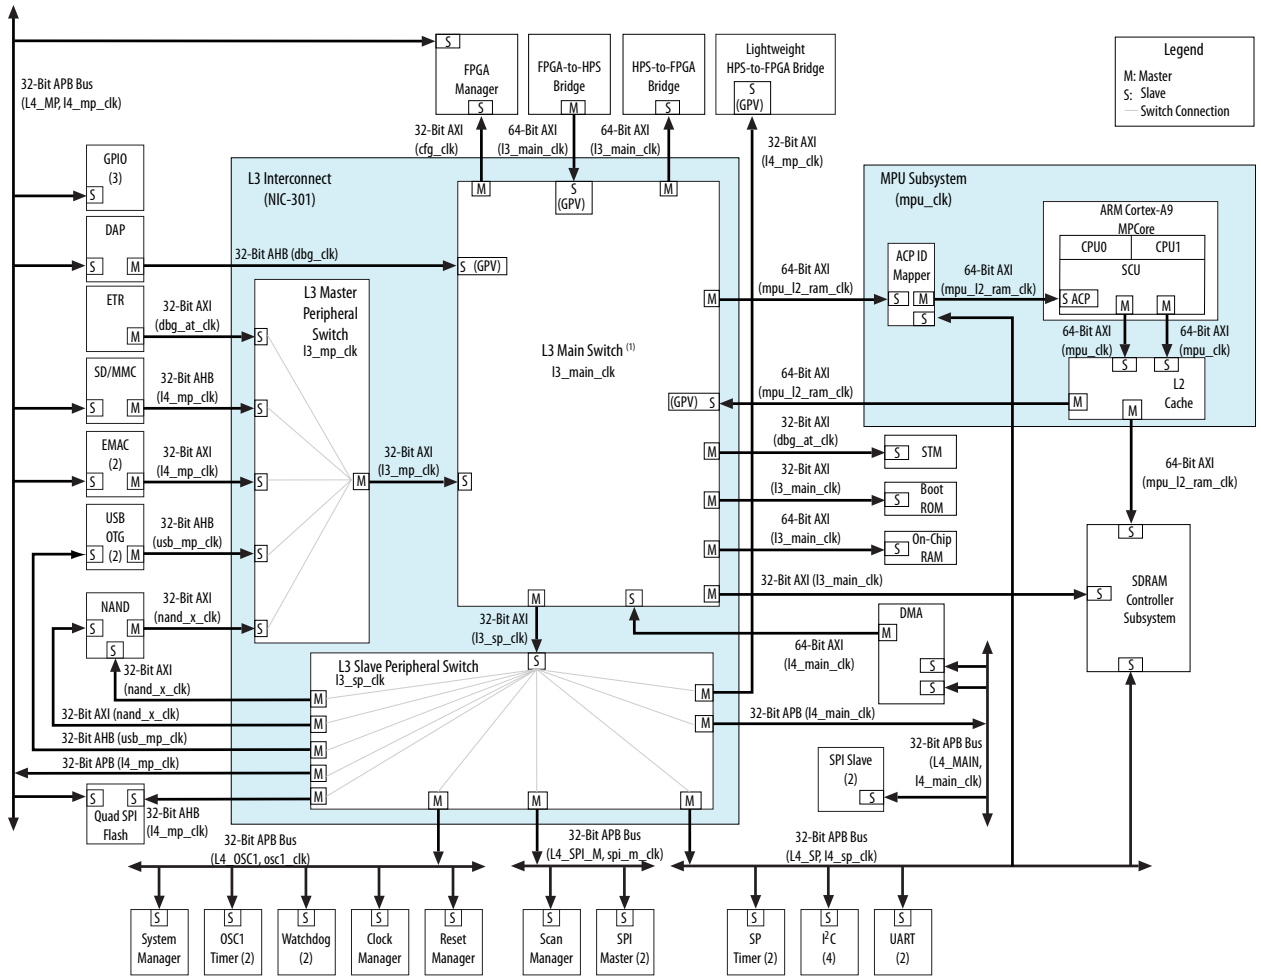
The system interconnect supports high-throughput peripheral devices. The system interconnect has the following characteristics:

- Main internal data width of 64 bits
- Programmable master priority with single-cycle arbitration
- Full pipelining to prevent master stalls
- Programmable control for FIFO buffer transaction release
- ARM TrustZone® compliant, with additional security features configurable per master
- Multiple independent L4 buses

System Interconnect Block Diagram and System Integration

Interconnect Block Diagram

The following figure shows the L3 interconnect and L4 buses.



Note: System interconnect slaves are available for connection from peripheral masters. System interconnect masters connect to peripheral slaves. This terminology is the reverse of conventional terminology used in Qsys.

Related Information

- **Main Connectivity Matrix** on page 7-3

System Interconnect Architecture

The L3 interconnect is a partially-connected switch fabric. Not all masters can access all slaves.

Internally, the L3 interconnect is partitioned into the following subswitches:

- L3 interconnect
  - Interconnect used to transfer high-throughput 64-bit data
  - Operates at up to half the MPU main clock frequency
  - Provides masters with low-latency connectivity to AXI bridges, on-chip memories, SDRAM, and FPGA manager
- L3 master peripheral switch
  - Used to connect memory-mastering peripherals to the interconnect
  - 32-bit data width
  - Operates at up to half the interconnect clock frequency
- L3 slave peripheral switch
  - Used to provide access to level 3 and 4 slave interfaces for masters of the master peripheral and interconnects
  - 32-bit data width
  - Five independent L4 buses

The L3 master and slave peripheral switches are fully-connected crossbars. The L3 interconnect is a partially-connected crossbar. The following table shows the connectivity matrix of all the master and slave interfaces of the L3 interconnect.

Main Connectivity Matrix

The L3 master and slave peripheral switches are fully-connected crossbars. The L3 interconnect is a partially-connected crossbar. The following table shows the connectivity matrix of all the master and slave interfaces of the L3 interconnect.

Masters	Slaves							
	L3 Slave Peripheral Switch (1)	FPGA Manager	HPS-to-FPGA Bridge	ACP ID Mapper Data	STM	Boot ROM	On-Chip RAM	SDRAM Controller Subsystem L3 Data

L3 Address Space

The L3 address space is 4 GB and applies to all L3 masters except the MPU subsystem.

The L3 address space configurations contain the following regions:

- The peripherals region is the same as the peripherals region in the MPU address space except that the boot ROM and internal MPU registers (SCU and L2) are not accessible.
- The FPGA slaves region provides access to 960 MB of slaves in the FPGA fabric through the HPS-to-FPGA bridge.
- The SDRAM window region is 3 GB and provides access to the bottom 3 GB of the SDRAM address space. Any L3 master can access a cache-coherent view of SDRAM by performing a cacheable access through the ACP. The system interconnect `remap` register, in the `l3regs` group, determines if the 64 KB starting at address 0x0 is mapped to the on-chip RAM or the SDRAM. The SDRAM is mapped to address 0x0 on reset.
- The ACP window region is 1 GB and provides access to a configurable gigabyte-aligned region of the MPU address space. Registers in the ACP ID mapper control which gigabyte-aligned region of the MPU address space is accessed by the ACP window region. The ACP window region is used by L3 masters to perform coherent accesses into the MPU address space. For more information about the ACP ID mapper, refer to the *Cortex-A9 Microprocessor Unit Subsystem* chapter in volume 3 of the *Arria V Device Handbook, Volume 3*.

Table 7-1: L3 Address Space Regions

Region Name	Description	Base Address	Size
L3SDRAM	SDRAM window	0x00000000	0xC0000000 = 3 GB
L3LOWOCRAM	On-chip RAM remap bit is set	0x00000000	0x10000 = 64 KB
L3SDRAMLOWOCRAM	SDRAM window when on-chip RAM present	0x00100000	0xBFFF0000 = 3 GB - 64 KB
L3ACP	ACP window	0x80000000	0x40000000 = 1 GB

Address Remapping

The system interconnect supports address remapping through the `remap` register in the `l3regs` group. Remapping allows software to control which memory device (SDRAM, on-chip RAM, or boot ROM) is accessible at address 0x0 and the accessibility of the HPS-to-FPGA and lightweight HPS-to-FPGA bridges. The `remap` register is one of the NIC-301 Global Programmers View (GPV) registers. The following L3 masters can manipulate `remap`, because it maps into their address space:

- MPU
- FPGA-to-HPS bridge
- DAP

The remapping bits in the `remap` register are not mutually exclusive. The lowest order remap bit has higher priority when multiple slaves are remapped to the same address. Each bit allows different combinations of address maps to be formed. There is only one remapping register available in the GPV, so modifying the `remap` register affects all memory maps of all the masters of the system interconnect.

The effects of the remap bits can be categorized in the following groups:

- MPU master interface
  - L2 cache master 0 interface
- Non-MPU master interfaces
  - DMA master interface
  - Master peripheral interfaces
  - Debug Access Port (DAP) master interface
  - FPGA-to-HPS bridge master interface

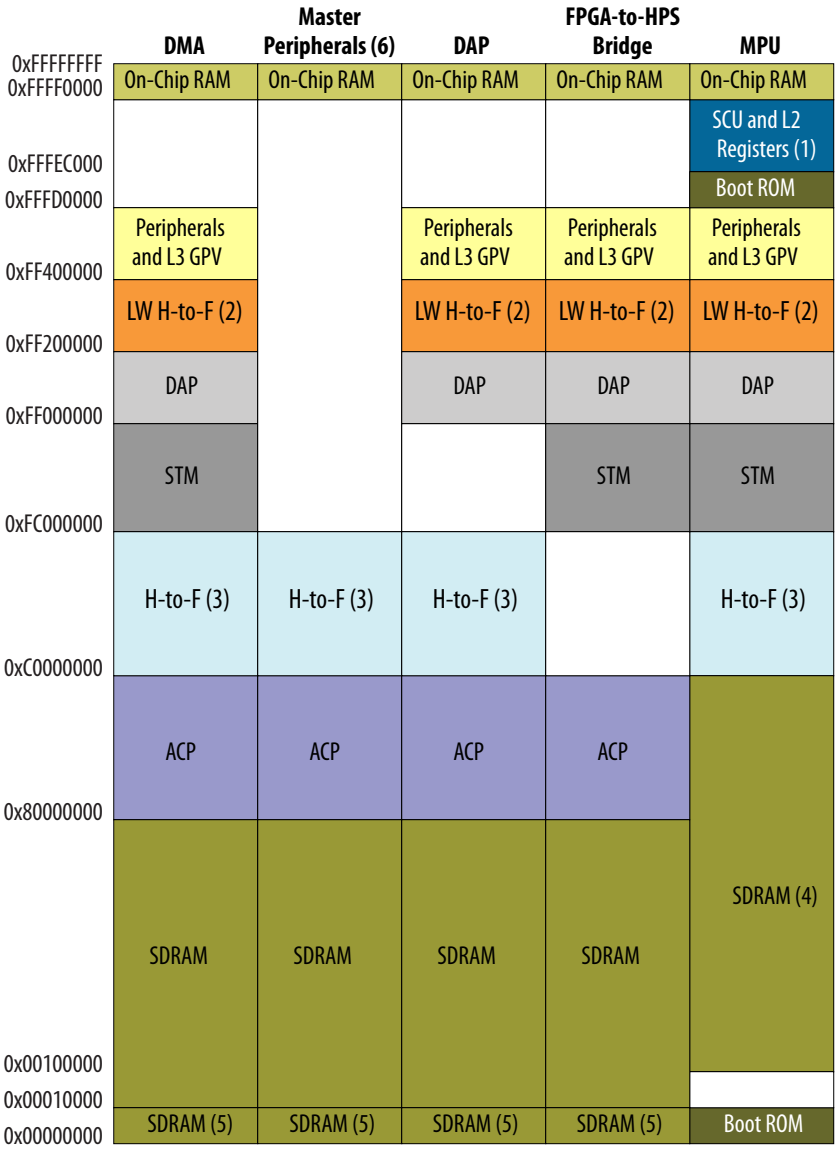
Available Address Maps

Figure 7-2: Address Maps for System Interconnect Masters

The following figure shows the default system interconnect address maps for all masters. The figure is not to scale.



Notes on Address Maps

(1) Transactions on these addresses are directly decoded by the SCU and L2 cache.

(2) This region can be configured to access slaves on the lightweight HPS-to-FPGA bridge, by using the `remap` register.

(3) This region can be configured to access slaves on the HPS-to-FPGA bridge, by using the `remap` register.

(4) The MPU accesses SDRAM through a dedicated port.

(5) This region can be configured to access on-chip RAM, by using the `remap` register.

(6) The following peripherals can master the interconnect:

- Ethernet MACs
- USB-2 OTG controllers
- NAND controllers
- ETR
- SD/MMC controller

For the MPU L3 master, either the boot ROM or on-chip RAM maps to address 0x0 and obscures the lowest 64 KB of SDRAM. The address space from 0x00010000 to 0x00100000 is not accessible because the MPU L2 filter registers only have a granularity of 1 MB. After booting completes, the MPU can change address filtering to use the lowest 1 MB of SDRAM.

For non-MPU masters, either the on-chip RAM or the SDRAM maps to address 0x0. When mapped to address 0x0, the on-chip RAM obscures the lowest 64 KB of SDRAM for non-MPU masters.

Related Information

remap on page 7-26
Description of the `remap` register

Memory Map Remap Bits

Bit Name	Bit Offset	Description
`mpuzero`	0	When set to 0, the boot ROM maps to address 0x0 for the MPU L3 master. When set to 1, the on-chip RAM maps to address 0x0 for the MPU L3 master. This bit has no effect on non-MPU masters. Note that regardless of this setting, the boot ROM also always maps to address 0xffff0000 and the on-chip RAM also always maps to address 0xfffd0000 for the MPU L3 master.
`nonmpuzero`	1	When set to 0, the SDRAM maps to address 0x0 for the non-MPU L3 masters. When set to 1, the on-chip RAM maps to address 0x0 for the non-MPU masters. This bit has no effect on the MPU L3 master. Note that regardless of this setting, the on-chip RAM also always maps to address 0xfffd0000 for the non-MPU L3 masters.
Reserved	2	Must always be set to 0.
`hps2fpga`	3	When set to 1, the HPS-to-FPGA bridge slave port is visible to the L3 masters. When set to 0, accesses to the associated address range return an AXI decode error to the master.

Bit Name	Bit Offset	Description
lwhp2fpga	4	When set to 1, the lightweight HPS-to-FPGA bridge slave port is visible to the L3 masters. When set to 0, accesses to the associated address range return an AXI decode error to the master.
Reserved	31:5	Must always be set to 0.

Note: L2 filter registers in the MPU subsystem, not the interconnect, allow the SDRAM to be remapped to address 0x0 for the MPU.

Master Caching and Buffering Overrides

Some of the peripheral masters connected to the system interconnect do not have the ability to drive the caching and buffering signals of their interfaces. The system manager provides registers so that you can enable cacheable and bufferable transactions for these masters. The system manager drives the caching and buffering signals of the following masters:

Master Peripheral	System Manager Register Group	Register
EMAC0 and EMAC1	emacgrp	l3master
USB OTG 0 and USB OTG 1	usbgrp	l3master
NAND flash	nandgrp	l3master
SD/MMC	sdmmcgrp	l3master

At reset time, the system manager drives the cache and buffering signals for these masters low. In other words, the masters listed do not support cacheable or bufferable accesses until you enable them after reset. There is no synchronization between the system manager and the system interconnect, so avoid changing these settings when any of the masters are active.

Related Information

System Manager on page 5-1
For more information about enabling or disabling these features, refer to the *System Manager* chapter.

Security

Slave Security

The interconnect enforces security through the slave settings. The slave settings are controlled by the address region control registers accessible through the GPV registers. Each L3 and L4 slave has its own security check and programmable security settings. After reset, every slave of the interconnect is set to a secure state (referred to as boot secure). The only accesses allowed to secure slaves are by secure masters.

The GPV can only be accessed by secure masters. The security state of the interconnect is not accessible through the GPV as the security registers are write-only. Any nonsecure accesses to the GPV receive a

DECERR response, and no register access is provided. Updates to the security settings through the GPV do not take effect until all transactions to the affected slave have completed.

Master Security

Masters of the system interconnect are either secure, nonsecure, or the security is set on a per transaction basis. The DAP and Ethernet masters only perform secure accesses. The L2 cache master 0, FPGA-to-HPS-bridge, and DMA perform secure and nonsecure accesses on a per transaction basis. All other system interconnect masters perform nonsecure accesses.

Accesses to secure slaves by unsecure masters result in a response of DECERR and the transaction does not reach the slave.

Information about the GPV write_qos registers

Cyclic Dependency Avoidance Schemes

The AXI protocol permits re-ordering of transactions. As a result, when routing concurrent multiple transactions from a single point of divergence to multiple slaves, the interconnect might need to enforce rules to prevent deadlock.

Each master of the interconnect is configured with one of three possible cyclic dependency avoidance schemes (CDAS). The same CDAS scheme is configured for both read and write transactions, but they operate independently.

Single Slave on page 7-10

Single Slave Per ID on page 7-11

Single Active Slave on page 7-11

Related Information

System Interconnect Master Properties on page 7-11
Contains descriptions of the CDAS implementation for the masters.

Single Slave

Single slave (SS) ensures the following conditions at a slave interface of a switch:

- All outstanding read transactions are to a single end destination.
- All outstanding write transactions are to a single end destination.

If a master issues another transaction to a different destination than the current destination for that transaction type (read or write), the network stalls the transactions until all the outstanding transactions of that type have completed.

Single Slave Per ID

Single slave per ID (SSPID) ensures the following conditions at a slave interface of a switch:

- All outstanding read transactions with the same ID go the same destination.
- All outstanding write transactions with the same ID go the same destination.

When a master issues a transaction, the following situations can occur:

- If the transaction has an ID that does not match any outstanding transactions, it passes the CDAS.
- If the transaction has an ID that matches the ID of an outstanding transaction, and the destinations also match, it passes the CDAS.
- If the transaction has an ID that matches the ID of an outstanding transaction, and the destinations do not match, the transaction fails the CDAS check and stalls.

Single Active Slave

Single active slave (SAS) is the same as the SSPID scheme, with an added check for write transactions. SAS ensures that a master cannot issue a new write address until all of the data from the previous write transaction has been sent.

System Interconnect Master Properties

The system interconnect connects to various slave interfaces through the L3 interconnect and L3 slave peripheral switch.

Table 7-2: System Interconnect Master Interfaces

TrustZone security:

- Secure: All transactions are marked TrustZone secure
- Nonsecure: All transactions are marked TrustZone non-secure
- Per transaction: Transactions can be marked TrustZone secure or TrustZone non-secure, depending on the state of the system interconnect master.

Issuance is based on the number of read, write, and total transactions.

The FIFO buffer depth for AXI is based on the AW, AR, R, W, and B channels. For AHB and APB, the depth is based on W, A, and D channels.

Master	Interface Width	Clock	Switch	TrustZone Security	GPV Access	CDAS	Issuance	FIFO Buffer Depth	Type
L2 cache M0	64	mpu_l2_ram_clk	L3 interconnect	Per Transaction	Yes	SSPID	7, 12, 19	2, 2, 2, 2, 2	AXI
FPGA-to-HPS bridge	64	l3_main_clk	L3 interconnect	Per Transaction	Yes	SAS	16, 16, 32	2, 2, 6, 6, 2	AXI
DMA	64	l4_main_clk	L3 interconnect	Per Transaction	No	SSPID	8, 8, 8	2, 2, 2, 2, 2	AXI

Upsizing Data Width Function

The upsizing function combines narrow transactions into wider transactions to increase the overall system bandwidth. Upsizing only packs data for read or write transactions that are cacheable. If the interconnect splits input-exclusive transactions into more than one output bus transaction, it removes the exclusive information from the multiple transactions it creates.

(13) Acceptance is based on the number of read, write, and total transactions.
(14) The FIFO buffer depth for AXI is based on the AW, AR, R, W, and B channels. For AHB and APB, the depth is based on W, A, and D channels.

The upsizing function can expand the data width by the following ratios:

- 1:2
- 1:4

If multiple responses from created transactions are combined into one response, then the following order of priority applies:

- `DECERR` is the highest priority
- `SLVERR` is the next highest priority
- `OKAY` is the lowest priority.

Related Information

http://infocenter.arm.com/
Additional information is available in the *AMBA Network Interconnect (NIC-301) Technical Reference Manual*, revision r2p3, which you can download from the ARM Infocenter website.

Incrementing Bursts

The interconnect converts all input `INCR` bursts that complete within a single output data width to an `INCR1` burst of the minimum `SIZE` possible, and packs all `INCR` bursts into `INCR` bursts of the optimal size possible for maximum data throughout.

Wrapping Bursts

All `WRAP` bursts are either passed through unconverted as `WRAP` bursts, or converted to one or two `INCR` bursts of the output bus. The interconnect converts input `WRAP` bursts that have a total payload less than the output data width to a single `INCR` burst.

Fixed Bursts

All `FIXED` bursts pass through unconverted.

Bypass Merge

Bypass merge is accessible through the GPV registers and is only accessible to secure masters. If the programmable bit `bypass_merge` is enabled, the interconnect does not alter any transactions that could pass through legally without alteration.

Downsizing Data Width Function

The downsizing function reduces the data width of a transaction to match the optimal data width at the destination. Downsizing does not merge multiple-transaction data narrower than the destination bus if the transactions are marked as noncacheable.

The downsizing function reduces the data width by the following ratios:

- 2:1
- 4:1

Incrementing Bursts

The interconnect converts INCR bursts that fall within the maximum payload size of the output data bus to a single INCR burst. It converts INCR bursts that are greater than the maximum payload size of the output data bus to multiple INCR bursts.

INCR bursts with a size that matches the output data width pass through unconverted.

The interconnect packs INCR bursts with a SIZE smaller than the output data width to match the output width whenever possible, using the upsizing function.

Related Information

Upsizing Data Width Function on page 7-14
For more information about AXI terms such as DECERR, WRAP, and INCR, refer to the *AMBA AXI Protocol Specification v1.0*, which you can download from the ARM website.

Wrapping Bursts

The interconnect always converts WRAP bursts to WRAP bursts of twice the length, up to the output data width maximum size of WRAP16, and treats the WRAP burst as two INCR bursts that can each be converted into one or more INCR bursts.

Fixed Bursts

The interconnect converts FIXED bursts to one or more INCR1 or INCRn bursts depending on the downsize ratio.

Bypass Merge

Bypass merge is accessible through the GPV registers and is only accessible to secure masters. If the programmable bit bypass_merge in the fn_mod2 register is enabled, the interconnect does not perform any packing of beats to match the optimal size for maximum throughput, up to the output data width size.

If an exclusive transaction is split into multiple transactions at the output of the downsizing function, the exclusive flag is removed and the master never receives an EXOKAY response. Response priority is the same as for the upsizing function.

  For more information about AXI terms such as DECERR, WRAP, and INCR, refer to the *AMBA AXI Protocol Specification v1.0*, which you can download from the ARM website.

Lock Support

Lock is not supported by the interconnect. For atomic accesses, masters can perform exclusive accesses when sharing data located in the HPS SDRAM.

Related Information

SDRAM Controller Subsystem on page 11-1
For more information about exclusive access support, refer to the *SDRAM Controller Subsystem* chapter.

FIFO Buffers and Clocks

The interconnect contains FIFO buffers in the majority of the interfaces exposed to the HPS master and slaves, as well as between the subswitches. These FIFO buffers also provide clock domain crossing for masters and slaves that operate at a different clock frequency than the switch they connect to.

Data Release Mechanism

For system interconnect ports with data FIFO buffers whose depth is greater than zero, you can set a write tidemark function, `wr_tidemark`. This tidemark level stalls the release of the transaction until one of the following situations occurs:

- The system interconnect receives the `WLAST` beat of a burst.
- The write data FIFO buffer becomes full.
- The number of occupied slots in the write data FIFO buffer exceeds the write tidemark.

Related Information

- **System Interconnect Master Properties** on page 7-11
  Indicates which master interfaces have data FIFO buffers with a nonzero depth
- **Interconnect Slave Properties** on page 7-12
  Indicates which slave interfaces have data FIFO buffers with a nonzero depth

System Interconnect Resets

The system interconnect has one reset signal. The reset manager drives this signal to the system interconnect on a cold or warm reset.

Related Information

Reset Manager on page 3-1

System Interconnect Address Map and Register Definitions

This section lists the system interconnect register address map and describes the registers.

Note: System interconnect slaves are available for connection from peripheral masters. System interconnect masters connect to peripheral slaves. This terminology is the reverse of conventional terminology used in Qsys.

remap

The L3 interconnect has separate address maps for the various L3 Masters. Generally, the addresses are the same for most masters. However, the sparse interconnect of the L3 switch causes some masters to have holes in their memory maps. The remap bits are not mutually exclusive. Each bit can be set independently and in combinations. Priority for the bits is determined by the bit offset: lower offset bits take precedence over higher offset bits.

Module Instance	Base Address	Register Address

Master Register Group Register Descriptions

Registers associated with master interfaces in the L3 Interconnect. Note that a master in the L3 Interconnect connects to a slave in a module.

Offset: 0x2000

L4 MAIN Register Descriptions

Registers associated with the L4 MAIN master. This master is used to access the APB slaves on the L4 MAIN bus.

Offset: 0x0

fn_mod_bm_iss on page 7-53
Sets the issuing capability of the preceding switch arbitration scheme to multiple or single outstanding transactions.

fn_mod_bm_iss
Sets the issuing capability of the preceding switch arbitration scheme to multiple or single outstanding transactions.

Module Instance	Base Address	Register Address

Bit	Name	Description	Access	Reset
1	wr	**Value** **Description** 0x0 Multiple outstanding write transactions 0x1 Only a single outstanding write transaction	RW	0x0

Bit	Name	Description	Access	Reset
0	rd	Value Description 0x0 Multiple outstanding read transactions 0x1 Only a single outstanding read transaction	RW	0x0

ETR Register Descriptions

Registers associated with the ETR (TMC) slave interface. This slave is used by the ETR to access slaves attached to the L3/L4 Interconnect.

Offset: 0x5000

read_qos on page 7-95
QoS (Quality of Service) value for the read channel.

write_qos on page 7-95
QoS (Quality of Service) value for the write channel.

fn_mod on page 7-96
Sets the block issuing capability to multiple or single outstanding transactions.

read_qos

QoS (Quality of Service) value for the read channel.

Module Instance	Base Address	Register Address
l3regs	0xFF800000	0xFF847100

Offset: 0x47100

Access: RW

Bit Fields

Document Revision History

Table 7-4: Document Revision History

Date	Version	Changes
December 2014	2014.12.15	• Minor correction to table in "Available Address Maps" • Add detail to "L3 Address Space"

June 2014	2014.06.30	• Corrected master interconnect security properties for:
		  • Ethernet MAC
		  • ETR
		• Added address map and register descriptions

February 2014	2014.02.28	Maintenance release
December 2013	2013.12.30	Maintenance release
November 2012	1.2	Minor updates.

Date	Version	Changes
June 2012	1.1	• Added interconnect connectivity matrix. • Rearranged functional description sections. • Simplified address remapping section. • Added address map and register definitions section.
January 2012	1.0	Initial release.

HPS-FPGA Bridges 8

2014.12.15

av_5v4 Subscribe Send Feedback

This chapter describes the bridges in the hard processor system (HPS) used to communicate data between the FPGA fabric and HPS logic. The bridges use the Advanced Microcontroller Bus Architecture (AMBA) Advanced eXtensible Interface (AXI) protocol, and are based on the AMBA Network Interconnect (NIC-301).

The HPS contains the following HPS-FPGA bridges:

- FPGA-to-HPS Bridge
- HPS-to-FPGA Bridge
- Lightweight HPS-to-FPGA Bridge

Related Information

- **I2C Controller** on page 20-1
- **Functional Description of the FPGA-to-HPS Bridge** on page 8-4
- **HPS-to-FPGA Bridge Clocks and Resets** on page 8-48
- **Lightweight HPS-to-FPGA Bridge Clocks and Resets** on page 8-48
- **Security Manager**
  Information about security features in the HPS-FPGA bridges
- **http://infocenter.arm.com/**
  Additional information is available in the AMBA AXI Protocol Specification v1.0 and the AMBA Network Interconnect (NIC-301) Technical Reference Manual, which you can download from the ARM Infocenter website.

Features of the HPS-FPGA Bridges

The HPS-FPGA bridges allow masters in the FPGA fabric to communicate with slaves in the HPS logic and vice versa. For example, you can instantiate additional memories or peripherals in the FPGA fabric, and master interfaces belonging to components in the HPS logic can access them. You can also instantiate components such as a Nios® II processor in the FPGA fabric and their master interfaces can access memories or peripherals in the HPS logic.

Table 8-1: HPS-FPGA Bridge Features

Feature	FPGA-to-HPS Bridge	HPS-to-FPGA Bridge	Lightweight HPS-to-FPGA Bridge
Supports the AMBA AXI3 interface protocol	Y	Y	Y
Implements clock crossing and manages the transfer of data across the clock domains in the HPS logic and the FPGA fabric	Y	Y	Y
Performs data width conversion between the HPS logic and the FPGA fabric	Y	Y	Y
Allows configuration of FPGA interface widths at instantiation time	Y	Y	N

Each bridge consists of a master-slave pair with one interface exposed to the FPGA fabric and the other exposed to the HPS logic. The FPGA-to-HPS bridge exposes an AXI slave interface that you can connect to AXI master or Avalon-MM interfaces in the FPGA fabric. The HPS-to-FPGA and lightweight HPS-to-FPGA bridges expose an AXI master interface that you can connect to AXI or Avalon-MM slave interfaces in the FPGA fabric.

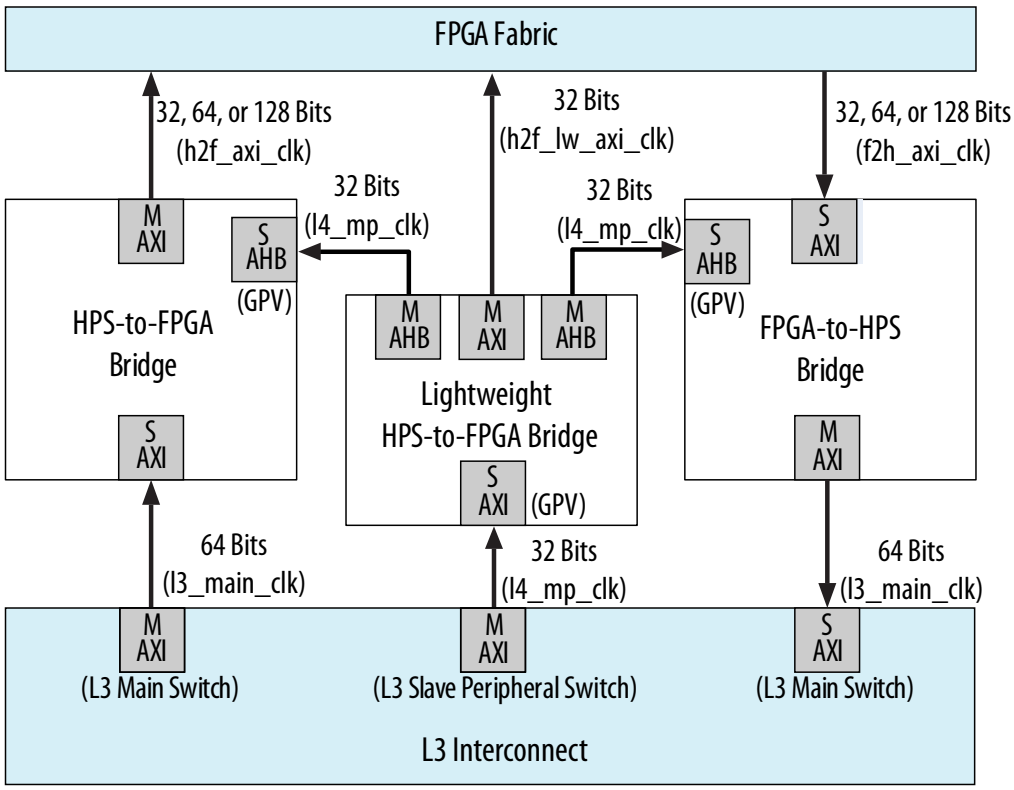
HPS-FPGA Bridges Block Diagram and System Integration

Figure 8-1: HPS-FPGA Bridge Connectivity

The following figure shows the HPS-FPGA bridges in the context of the FPGA fabric and the L3 interconnect to the HPS. Each master (M) and slave (S) interface is shown with its data width(s). The clock domain for each interconnect is shown in parentheses.



The HPS-to-FPGA bridge is mastered by the level 3 (L3) main switch and the lightweight HPS-to-FPGA bridge is mastered by the L3 slave peripheral switch.

The FPGA-to-HPS bridge masters the L3 main switch, allowing any master implemented in the FPGA fabric to access most slaves in the HPS. For example, the FPGA-to-HPS bridge can access the accelerator coherency port (ACP) of the Cortex-A9 MPU subsystem to perform cache-coherent accesses to the SDRAM subsystem.

All three bridges contain global programmers view (GPV) registers. The GPV registers control the behavior of the bridge. Access to the GPV registers of all three bridges is provided through the lightweight HPS-to-FPGA bridge.

Functional Description of the HPS-FPGA Bridges

The Global Programmers View

The HPS-to-FPGA bridge includes a set of registers called the GPV. The GPV provides settings to control the bridge properties and behavior. Access to the GPV registers of all three bridges is provided through the lightweight HPS-to-FPGA bridge.

The GPV registers can only be accessed by secure masters in the HPS or the FPGA fabric.

Functional Description of the FPGA-to-HPS Bridge

The FPGA-to-HPS bridge provides access to the peripherals and memory in the HPS. This access is available to any master implemented in the FPGA fabric. You can configure the bridge slave, which is exposed to the FPGA fabric, to support 32-, 64-, or 128-bit data. The master interface of the bridge, connected to the L3 interconnect, has a data width of 64 bits.

Table 8-2: FPGA-to-HPS Bridge Properties

The following table lists the properties of the FPGA-to-HPS bridge, including the configurable slave interface exposed to the FPGA fabric.

Bridge Property	FPGA Slave Interface	L3 Master Interface
Data width[15]	32, 64, or 128 bits	64 bits
Clock domain	`f2h_axi_clk`	`l3_main_clk`
Byte address width	32 bits	32 bits
ID width	8 bits	8 bits
Read acceptance	16 transactions	16 transactions
Write acceptance	16 transactions	16 transactions
Total acceptance	32 transactions	32 transactions

The FPGA-to-HPS bridge address map contains a GPV. The GPV registers provide settings that adjust the bridge slave properties when the FPGA slave interface is configured to be 32 or 128 bits wide. The slave issuing capability can be adjusted, through the `fn_mod` register, to allow one or multiple transactions to be outstanding in the HPS. The slave bypass merge feature can also be enabled, through the `bypass_merge` bit in the `fn_mod2` register. This feature ensures that the upsizing and downsizing logic does not alter any transactions when the FPGA slave interface is configured to be 32 or 128 bits wide.

Note: It is critical to provide the correct `l4_mp_clk` clock to support access to the GPV, as described in "GPV Clocks".

[15] The bridge slave data width is user-configurable at the time you instantiate the HPS component in your system.

FPGA-to-HPS Access to ACP

When the error correction code (ECC) option is enabled in the level 2 (L2) cache controller, all accesses from the FPGA-to-HPS bridge to the ACP must be 64 bits wide and aligned on 8-byte boundaries after up- or downsizing takes place.

Table 8-3: FPGA Master and FPGA-to-HPS Bridge Configurations

The following table lists some possible master and FPGA-to-HPS bridge slave configurations that support accesses to the L2 cache with ECC enabled.

Soft Logic Master Width	Soft Logic Master Alignment	Soft Logic Master Burst Size (Width)	Soft Logic Master Burst Length	FPGA-to-HPS Bridge Slave Width
32 bits	8 bytes	4 bytes	2, 4, 6, 8, 10, 12, 14, or 16 beats	32 bits
64 bits	8 bytes	8 bytes	1 to 16 beats	32 bits
128 bits	8 or 16 bytes	8 or 16 bytes	1 to 16 beats	32 bits
32 bits	8 bytes	4 bytes	2, 4, 6, 8, 10, 12, 14, or 16 beats	64 bits
64 bits	8 bytes	8 bytes	1 to 16 beats	64 bits
128 bits	8 or 16 bytes	8 or 16 bytes	1 to 16 beats	64 bits
32 bits	8 bytes	4 bytes	2, 4, 6, 8, 10, 12, 14, or 16 beats	128 bits
64 bits	8 bytes	8 bytes	1 to 16 beats	128 bits
128 bits	8 or 16 bytes	8 or 16 bytes	1 to 16 beats	128 bits

FPGA-to-HPS Bridge Slave Signals

The FPGA-to-HPS bridge slave address channels support user-sideband signals, routed to the ACP in the MPU subsystem. All the signals have a fixed width except the data and write strobes for the read and write data channels. The variable width signals depend on the data width setting of the bridge.

The following tables list all the signals exposed by the FPGA-to-HPS slave interface to the FPGA fabric.

Table 8-4: FPGA-to-HPS Bridge Slave Write Address Channel Signals

Signal	Width	Direction	Description
AWID	8 bits	Input	Write address ID
AWADDR	32 bits	Input	Write address
AWLEN	4 bits	Input	Burst length
AWSIZE	3 bits	Input	Burst size
AWBURST	2 bits	Input	Burst type
AWLOCK	2 bits	Input	Lock type—Valid values are 00 (normal access) and 01 (exclusive access)
AWCACHE	4 bits	Input	Cache policy type
AWPROT	3 bits	Input	Protection type
AWVALID	1 bit	Input	Write address channel valid
AWREADY	1 bit	Output	Write address channel ready
AWUSER	5 bits	Input	User sideband signals

Table 8-5: FPGA-to-HPS Bridge Slave Write Data Channel Signals

Signal	Width	Direction	Description
WID	8 bits	Input	Write ID
WDATA	32, 64, or 128 bits	Input	Write data
WSTRB	4, 8, or 16 bits	Input	Write data strobes
WLAST	1 bit	Input	Write last data identifier
WVALID	1 bit	Input	Write data channel valid
WREADY	1 bit	Output	Write data channel ready

Table 8-6: FPGA-to-HPS Bridge Slave Write Response Channel Signals

Signal	Width	Direction	Description
BID	8 bits	Output	Write response ID

Signal	Width	Direction	Description
BRESP	2 bits	Output	Write response
BVALID	1 bit	Output	Write response channel valid
BREADY	1 bit	Input	Write response channel ready

Table 8-7: FPGA-to-HPS Bridge Slave Read Address Channel Signals

Signal	Width	Direction	Description
ARID	8 bits	Input	Read address ID
ARADDR	32 bits	Input	Read address
ARLEN	4 bits	Input	Burst length
ARSIZE	3 bits	Input	Burst size
ARBURST	2 bits	Input	Burst type
ARLOCK	2 bits	Input	Lock type—Valid values are 00 (normal access) and 01 (exclusive access)
ARCACHE	4 bits	Input	Cache policy type
ARPROT	3 bits	Input	Protection type
ARVALID	1 bit	Input	Read address channel valid
ARREADY	1 bit	Output	Read address channel ready
ARUSER	5 bits	Input	Read user sideband signals

Table 8-8: FPGA-to-HPS Bridge Slave Read Data Channel Signals

Signal	Width	Direction	Description
RID	8 bits	Output	Read ID
RDATA	32, 64, or 128 bits	Output	Read data
RRESP	2 bits	Output	Read response
RLAST	1 bit	Output	Read last data identifier
RVALID	1 bit	Output	Read data channel valid

Signal	Width	Direction	Description
RREADY	1 bit	Input	Read data channel ready

Functional Description of the HPS-to-FPGA Bridge

The HPS-to-FPGA bridge provides a configurable-width, high-performance master interface to the FPGA fabric. The bridge provides most masters in the HPS with access to logic, peripherals, and memory implemented in the FPGA. The effective size of the address space is 0x3FFF0000, or 1 gigabyte (GB) minus the 64 megabytes (MB) occupied by peripherals, lightweight HPS-to-FPGA bridge, on-chip RAM, and boot ROM in the HPS. You can configure the bridge master exposed to the FPGA fabric for 32-, 64-, or 128-bit data. The amount of address space exposed to the MPU subsystem can also be reduced through the L2 cache address filtering mechanism.

The slave interface of the bridge in the HPS logic has a data width of 64 bits. The bridge provides width adaptation and clock crossing logic that allows the logic in the FPGA to operate in any clock domain, asynchronous from the HPS.

Note: The HPS-to-FPGA bridge is accessed if the MPU boots from the FPGA. Before the MPU boots from the FPGA, the FPGA portion of the SoC device must be configured, and the HPS-to-FPGA bridge must be remapped into addressable space.

Table 8-9: HPS-to-FPGA Bridge Properties

The following table lists the properties of the HPS-to-FPGA bridge, including the configurable master interface exposed to the FPGA fabric.

Bridge Property	L3 Slave Interface	FPGA Master Interface
Data width [16]	64 bits	32, 64, or 128 bits
Clock domain	`l3_main_clk`	`h2f_axi_clk`
Byte address width	32 bits	30 bits
ID width	12 bits	12 bits
Read acceptance	16 transactions	16 transactions
Write acceptance	16 transactions	16 transactions
Total acceptance	32 transactions	32 transactions

The HPS-to-FPGA bridge's GPV, described in "The Global Programmers View", provides settings to adjust the bridge master properties. The master issuing capability can be adjusted, through the `fn_mod` register, to allow one or multiple transactions to be outstanding in the FPGA fabric. The master bypass merge feature can also be enabled, through the `bypass_merge` bit in the `fn_mod2` register. This feature ensures that the upsizing and downsizing logic does not alter any transactions when the FPGA master interface is configured to be 32 or 128 bits wide.

Note: It is critical to provide the correct `l4_mp_clk` clock to support access to the GPV, as described in "GPV Clocks".

Functional Description of the Lightweight HPS-to-FPGA Bridge

The lightweight HPS-to-FPGA bridge provides a lower-performance interface to the FPGA fabric. This interface is useful for accessing the control and status registers of soft peripherals. The bridge provides a 2 MB address space and access to logic, peripherals, and memory implemented in the FPGA fabric. The MPU subsystem, direct memory access (DMA) controller, and debug access port (DAP) can use the lightweight HPS-to-FPGA bridge to access the FPGA fabric or GPV. Master interfaces in the FPGA fabric can also use the lightweight HPS-to-FPGA bridge to access the GPV registers in all three bridges.

The bridge master exposed to the FPGA fabric has a fixed data width of 32 bits. The slave interface of the bridge in the HPS logic has a fixed data width of 32 bits.

Use the lightweight HPS-to-FPGA bridge as a secondary, lower-performance master interface to the FPGA fabric. With a fixed width and a smaller address space, the lightweight bridge is useful for low-bandwidth traffic, such as memory-mapped register accesses to FPGA peripherals. This approach diverts traffic from the high-performance HPS-to-FPGA bridge, and can improve both CSR access latency and overall system performance.

Table 8-15: Lightweight HPS-to-FPGA Bridge Properties

This table lists the properties of the lightweight HPS-to-FPGA bridge, including the master interface exposed to the FPGA fabric.

Bridge Property	L3 Slave Interface	FPGA Master Interface
Data width	32 bits	32 bits
Clock domain	`l4_mp_clk`	`h2f_lw_axi_clk`
Byte address width	32 bits	21 bits
ID width	12 bits	12 bits
Read acceptance	16 transactions	16 transactions
Write acceptance	16 transactions	16 transactions
Total acceptance	32 transactions	32 transactions

The lightweight HPS-to-FPGA bridge has three master interfaces. The master interface connected to the FPGA fabric provides a lightweight interface from the HPS to custom logic in the FPGA fabric. The two other master interfaces, connected to the HPS-to-FPGA and FPGA-to-HPS bridges, allow you to access the GPV registers for each bridge.

The lightweight HPS-to-FPGA bridge also has a set of registers GPV to control the behavior of its four interfaces (one slave and three masters).

The GPV allows you to set the bridge's issuing capabilities to support single or multiple transactions. The GPV also lets you set a write tidemark through the `wr_tidemark` register, to control how much data is buffered in the bridge before data is written to slaves in the FPGA fabric.

Note: It is critical to provide correct clock settings for the lightweight HPS-to-FPGA bridge, even if your design does not use this bridge. The `l4_mp_clk` clock is required for GPV access on the HPS-to-FPGA and FPGA-to-HPS bridges.

Lightweight HPS-to-FPGA Bridge Master Signals

All the lightweight HPS-to-FPGA bridge master signals have a fixed width.

The following tables list all the signals exposed by the lightweight HPS-to-FPGA master interface to the FPGA fabric.

Table 8-16: Lightweight HPS-to-FPGA Bridge Master Write Address Channel Signals

Signal	Width	Direction	Description
AWID	12 bits	Output	Write address ID
AWADDR	21 bits	Output	Write address
AWLEN	4 bits	Output	Burst length
AWSIZE	3 bits	Output	Burst size
AWBURST	2 bits	Output	Burst type
AWLOCK	2 bits	Output	Lock type—Valid values are 00 (normal access) and 01 (exclusive access)
AWCACHE	4 bits	Output	Cache policy type
AWPROT	3 bits	Output	Protection type
AWVALID	1 bit	Output	Write address channel valid
AWREADY	1 bit	Input	Write address channel ready

Table 8-17: Lightweight HPS-to-FPGA Bridge Master Write Data Channel Signals

Signal	Width	Direction	Description
WID	12 bits	Output	Write ID
WDATA	32 bits	Output	Write data
WSTRB	4 bits	Output	Write data strobes
WLAST	1 bit	Output	Write last data identifier
WVALID	1 bit	Output	Write data channel valid
WREADY	1 bit	Input	Write data channel ready

Table 8-18: Lightweight HPS-to-FPGA Bridge Master Write Response Channel Signals

Signal	Width	Direction	Description
BID	12 bits	Input	Write response ID

Signal	Width	Direction	Description
BRESP	2 bits	Input	Write response
BVALID	1 bit	Input	Write response channel valid
BREADY	1 bit	Output	Write response channel ready

Table 8-19: Lightweight HPS-to-FPGA Bridge Master Read Address Channel Signals

Signal	Width	Direction	Description
ARID	12 bits	Output	Read address ID
ARADDR	21 bits	Output	Read address
ARLEN	4 bits	Output	Burst length
ARSIZE	3 bits	Output	Burst size
ARBURST	2 bits	Output	Burst type
ARLOCK	2 bits	Output	Lock type—Valid values are 00 (normal access) and 01 (exclusive access)
ARCACHE	4 bits	Output	Cache policy type
ARPROT	3 bits	Output	Protection type
ARVALID	1 bit	Output	Read address channel valid
ARREADY	1 bit	Input	Read address channel ready

Table 8-20: Lightweight HPS-to-FPGA Bridge Master Read Data Channel Signals

Signal	Width	Direction	Description
RID	12 bits	Input	Read ID
RDATA	32 bits	Input	Read data
RRESP	2 bits	Input	Read response
RLAST	1 bit	Input	Read last data identifier
RVALID	1 bit	Input	Read data channel valid
RREADY	1 bit	Output	Read data channel ready

Clocks and Resets

FPGA-to-HPS Bridge Clocks and Resets

The master interface of the bridge in the HPS logic operates in the `l3_main_clk` clock domain. The slave interface exposed to the FPGA fabric operates in the `f2h_axi_clk` clock domain provided by the user logic. The bridge provides clock crossing logic that allows the logic in the FPGA to operate in any clock domain, asynchronous from the HPS.

The FPGA-to-HPS bridge has one reset signal, `fpga2hps_bridge_rst_n`. The reset manager drives this signal to FPGA-to-HPS bridge on a cold or warm reset.

Lightweight HPS-to-FPGA Bridge Clocks and Resets

The master interface into the FPGA fabric operates in the `h2f_lw_axi_clk` clock domain. The clock is provided by custom logic in the FPGA fabric. The slave interface of the bridge in the HPS logic operates in the `l4_mp_clk` clock domain. The bridge provides clock crossing logic that allows the logic in the FPGA to operate in any clock domain, asynchronous from the HPS.

The lightweight HPS-to-FPGA bridge has one reset signal, `lwhps2fpga_bridge_rst_n`. The reset manager drives this signal to the lightweight HPS-to-FPGA bridge on a cold or warm reset.

Taking HPS-FPGA Bridges Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the MPU boots up, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

Related Information

Modules Requiring Software Deassert on page 3-9
Reset register names

GPV Clocks

The FPGA-to-HPS and HPS-to-FPGA bridges have GPV slave interfaces, mastered by the lightweight HPS-to-FPGA bridge. These interfaces operate in the `l4_mp_clk` clock domain. Even if you do not use the lightweight HPS-to-FPGA bridge in your FPGA design, you must ensure that a valid `l4_mp_clk` clock is being generated, so that the GPV registers in the HPS-to-FPGA and FPGA-to-HPS bridges can be programmed. The GPV logic in all three bridges is in the `l4_mp_clk` domain.

Related Information

The Global Programmers View on page 8-4

Data Width Sizing

The HPS-to-FPGA and FPGA-to-HPS bridges allow 32-, 64-, and 128-bit interfaces to be exposed to the FPGA fabric. For 32-bit and 128-bit interfaces, the bridge performs data width conversion to the fixed 64-bit interface within the HPS. This conversion is called *upsizing* in the case of data being converted from a 64-bit interface to a 128-bit interface. It is called *downsizing* in the case of data being converted from a 64-bit interface to a 32-bit interface. If an exclusive access is split into multiple transactions, the transactions lose their exclusive access information.

During the upsizing or downsizing process, transactions can also be resized using a data merging technique. For example, in the case of a 32-bit to 64-bit upsizing, if the size of each beat entering the bridge's 32-bit interface is only two bytes, the bridge can merge up to four beats to form a single 64-bit beat. Similarly, in the case of a 128-bit to 64-bit downsizing, if the size of each beat entering the bridge's 128-bit interface is only four bytes, the bridge can merge two beats to form a single 64-bit beat.

The bridges do not perform transaction merging for accesses marked as noncacheable.

Note: You can set the `bypass_merge` bit in the GPV to prevent the bridge from merging data and responses. If the bridge merges multiple responses into a single response, that response is the one with the highest priority. The response types have the following priorities:

1. DECERR
2. SLVERR
3. OKAY

HPS-FPGA Bridges Address Map and Register Definitions

The address map and register definitions for the HPS-FPGA bridges consist of the following regions:

- FPGA-to-HPS Bridge Module
- HPS-to-FPGA Bridge Module

Cortex-A9 Microprocessor Unit Subsystem

9

2014.12.15

av_5v4

The hard processor system (HPS) in the Altera SoC device includes a stand-alone, full-featured ARM Cortex-A9 MPCore, dual-core 32-bit application processor. The Cortex-A9 microprocessor unit (MPU) subsystem is composed of a Cortex-A9 MPCore, a level 2 (L2) cache, an Accelerator Coherency Port (ACP) ID mapper, and debugging modules.

Features of the Cortex-A9 MPU Subsystem

The Altera Cortex-A9 MPU subsystem provides the following features:

- Two ARM Cortex-A9 processors, each with the following support modules:
  - ARM NEON single instruction, multiple data (SIMD) coprocesoor
  - Memory Management Unit (MMU)
  - 32 KB instruction cache
  - 32 KB data cache
  - Private interval timer
  - Private watchdog timer
- Interrupt controller
- Global timer
- Snoop control unit (SCU)
- Accelerator Coherency Port (ACP)
- ARM L2 cache controller
- TrustZone system security extensions
- Symmetric multiprocessing (SMP) and asymmetric multiprocessing (AMP) modes
- Debugging modules

The Cortex-A9 MPU incorporates the following core and L2 cache versions:

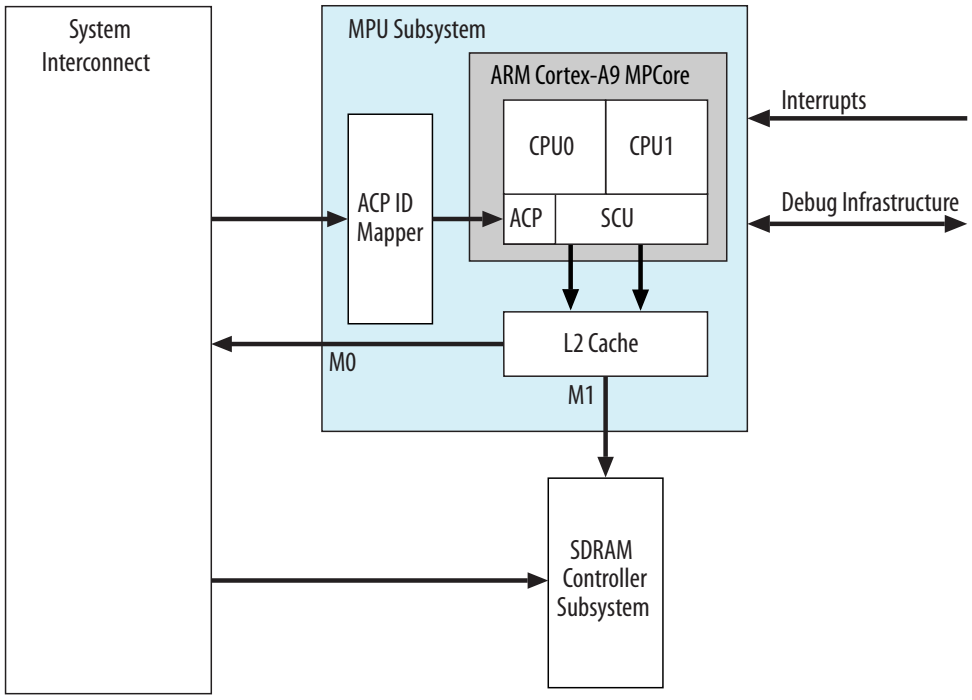
Table 9-1: Cortex-A9 MPU Module Versions

Feature	Version
Cortex-A9 Core	r3p0
L2-310 Level 2 Cache Controller	r3p3

Cortex-A9 MPU Subsystem Block Diagram and System Integration

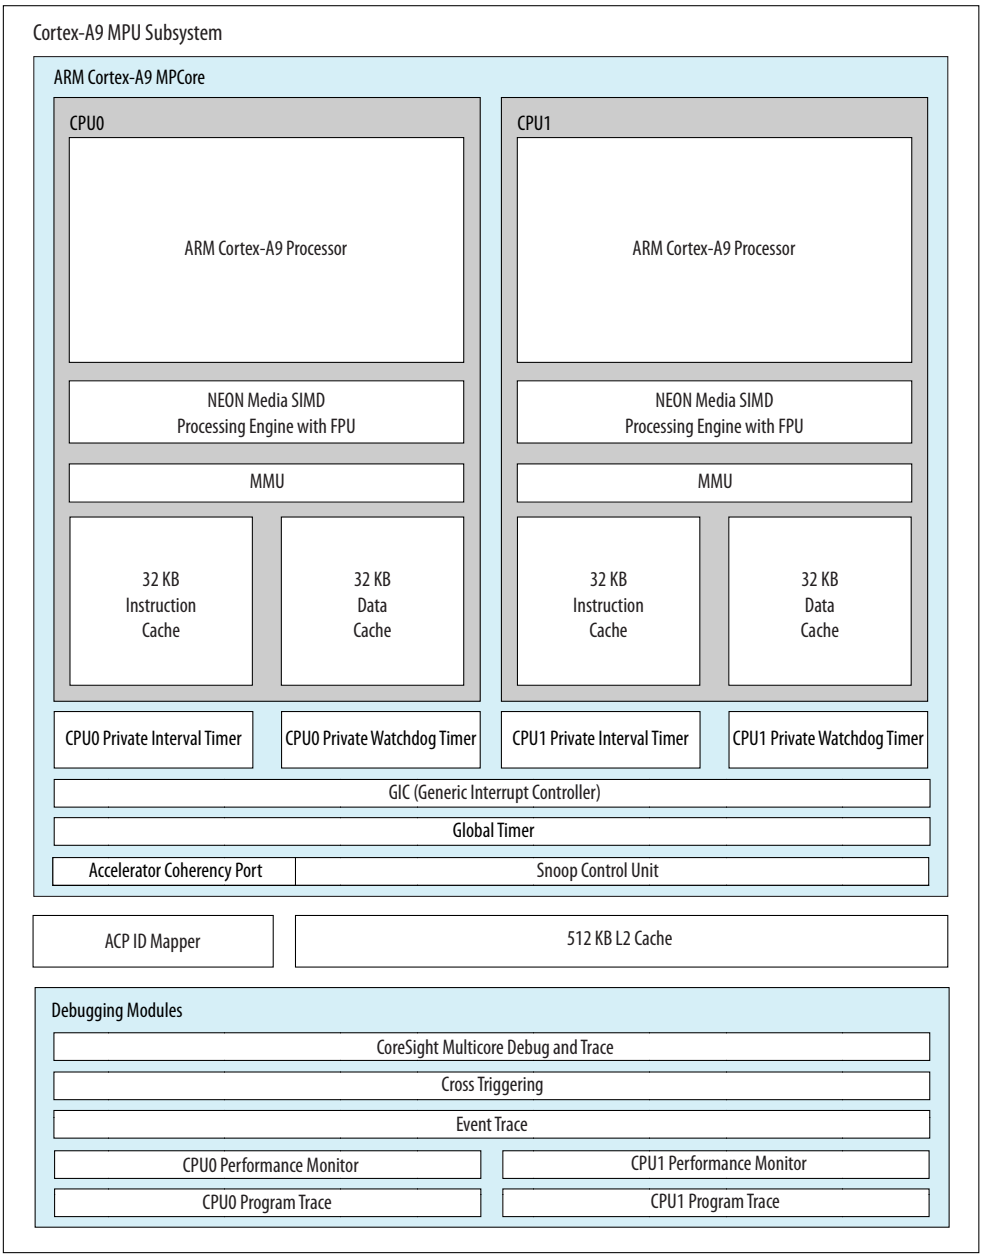
Cortex-A9 MPU Subsystem with System Interconnect

This block diagram shows a dual-core MPU subsystem in the context of the HPS, with the L2 cache. The L2 cache can access either the system interconnect or the SDRAM.



Cortex-A9 MPU Subsystem Internals

This figure shows a block diagram of the Altera Cortex-A9 MPU subsystem.



Cortex-A9 MPCore

Functional Description

The ARM Cortex-A9 MPCore contains the following sub-modules:

- Two Cortex-A9 Revision r3p0 processors operating in SMP or AMP mode
- Snoop control unit (SCU)
- Private interval timer for each processor core
- Private watchdog timer for each processor core
- Global timer
- Interrupt controller

Each transaction originating from the Altera Cortex-A9 MPU subsystem can be flagged as secure or non-secure.

Related Information

Cortex-A9 MPU Subsystem Register Implementation on page 9-61
For more information regarding the Cortex MPU Subsystem Address Map, refer to the *Cortex-A9 MPU Subsystem Register Implementation* section.

Implementation Details

Table 9-2: Cortex-A9 MPCore Processor Configuration

This table shows the parameter settings for the Altera Cortex-A9 MPCore.

Feature	Options
Cortex-A9 processors	2
Instruction cache size per Cortex-A9 processor	32 KB
Data cache size per Cortex-A9 processor	32 KB
TLB size per Cortex-A9 processor	128 entries
Media Processing Engine with NEON™ technology per Cortex-A9 processor(17)	Included
Preload Engine per Cortex-A9 processor	Included
Number of entries in the Preload Engine FIFO per Cortex-A9 processor	16
Jazelle DBX extension per Cortex-A9 processor	Full
Program Trace Macrocell (PTM) interface per Cortex-A9 processor	Included
Support for parity error detection (18)	Included
Master ports	Two
Accelerator Coherency Port	Included

Related Information

For more information regarding the Cortex-A9 MPCore features and functions.

(17) Includes support for floating-point operations.

(18) For a description of the parity error scheme and parity error signals, refer to the Cortex-A9 Technical Reference Manual, available on the ARM website (infocenter.arm.com).

Cortex-A9 Processor

Each Cortex-A9 processor includes the following hardware blocks:

- ARM NEON™ single instruction, multiple data (SIMD) coprocessor with vector floating-point (VFP) v3 double-precision floating point unit for media and signal processing acceleration
  - Single- and double-precision IEEE-754 floating point math support
  - Integer and polynomial math support
- Level 1 (L1) cache with parity checking
  - 32 KB four-way set-associative instruction cache
  - 32 KB four-way set-associative data cache
- CoreSight™ Program Trace Macrocell (PTM) supporting instruction trace

Each Cortex-A9 processor supports the following features:

- Dual-issue superscalar pipeline with advanced branch prediction
- Out-of-order (OoO) dispatch and speculative instruction execution
- 2.5 million instructions per second (MIPS) per MHz, based on the Dhrystone 2.1 benchmark
- 128-entry translation lookaside buffer (TLB)
- TrustZone security extensions
- Configurable data endianness
- Jazelle® DBX Extensions for byte-code dynamic compiler support
- The Cortex-A9 processor architecture supports the following instruction sets:
  - The ARMv7-A performance-optimized instruction set
  - The memory-optimized Thumb®-2 mixed instruction set
    - Improves energy efficiency
    - 31% smaller memory footprint
    - 38% faster than the original Thumb instruction set
  - The Thumb instruction set—supported for legacy applications
- Each processor core in the Altera HPS includes an MMU to support the memory management requirements of common modern operating systems.

The Cortex-A9 processors are designated CPU0 and CPU1.

Related Information

http://infocenter.arm.com/
Detailed documentation of ARM Cortex-A9 series processors is available on the ARM Infocenter website.

Reset

When a cold or warm reset is issued in the MPU, CPU0 is released from reset automatically. If CPU1 is present, then its reset signals are left asserted when a cold or warm reset is issued. After CPU0 comes out of reset, it can deassert CPU1's reset signals by clearing the `CPU1` bit in the MPU Module Reset (`mpumodrst`) register in the Reset Manager.

Related Information

Reset Manager on page 3-1

Interactive Debugging Features

Each Cortex-A9 processor has built-in debugging capabilities, including six hardware breakpoints (two with Context ID comparison capability) and four watchpoints. The interactive debugging features can be controlled by external JTAG tools or by processor-based monitor code.

Related Information

http://infocenter.arm.com/
For more information about the interactive debugging system, refer to the *Debug* chapter of the Cortex-A9 Technical Reference Manual, available on the ARM Infocenter website.

L1 Caches

Cache memory that is closely coupled with an associated processor is called level 1, or L1 cache. Each Cortex-A9 processor has two independent 32 KB L1 caches—one for instructions and one for data—allowing simultaneous instruction fetches and data access. Each L1 cache is four-way set associative, with 32 bytes per line, and supports parity checking.

Note: A parity error cannot be recovered and is indicated by one of the parity error interrupt signals. On a parity error interrupt, you can reset the system or perform further actions depending on the indication of the interrupt signals.

Cache Latency

Latency for cache hits and misses varies.

The latency for an L1 cache hit is 1 clock. The latency for an L1 cache miss and L2 cache hit is 6 clocks best case. Latency in the L2 cache can vary depending on other operations in the L2. Parity and ECC settings have no effect on latency. A single-bit ECC error is corrected during the L2 read, but is not re-written to the L2 RAM.

Preload Engine

The preload engine (PLE) is a hardware block that enables the L2 cache to preload selected regions of memory.

The PLE signals the L2 cache when a cache line is needed in the L2 cache, by making the processor data master port start fetching the data. The processor data master does not complete the fetch or return the data to the processor. However, the L2 cache can then proceed to load the cache line. The data is only loaded to the L2 cache, not to the L1 cache or processor registers.

The preload functionality is under software control. The following PLE control parameters must be programmed:

- Programmed parameters, including the following:
  - Base address
  - Length of stride
  - Number of blocks
- A valid bit
- TrustZone memory protection for the cache memory, with an NS (non-secure) state bit
- A translation table base (TTB) address
- An Address Space Identifier (ASID) value

Related Information

http://infocenter.arm.com/

For more information about the PLE, refer to the *Preload Engine* chapter of the *Cortex-A9 Technical Reference Manual*, available on the ARM Infocenter website.

Floating Point Unit

Each ARM® Cortex-A9 processor includes full support for IEEE-754 floating point operations.

The floating-point unit (FPU) fully supports half-, single-, and double-precision variants of the following operations:

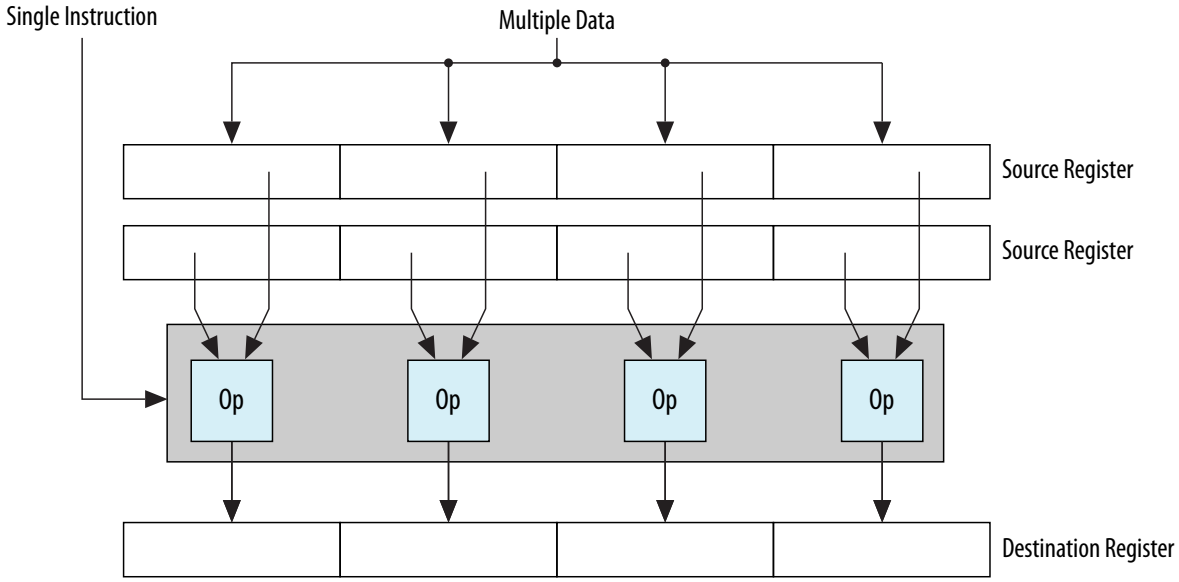
- Add
- Subtract
- Multiply
- Divide
- Multiply and accumulate (MAC)
- Square root

The FPU also converts between floating-point data formats and integers, including special operations to round towards zero required by high-level languages.

NEON Multimedia Processing Engine

The NEON™ multimedia processing engine (MPE) provides hardware acceleration for media and signal processing applications. Each ARM Cortex-A9 processor includes an ARM NEON MPE that supports SIMD processing.

Single Instruction, Multiple Data (SIMD) Processing



Features of the NEON MPE

The NEON™ processing engine accelerates multimedia and signal processing algorithms such as video encoding and decoding, 2-D and 3-D graphics, audio and speech processing, image processing, telephony, and sound synthesis.

The Cortex-A9 NEON MPE performs the following types of operations:

- SIMD and scalar single-precision floating-point computations
- Scalar double-precision floating-point computation
- SIMD and scalar half-precision floating-point conversion
- 8-bit, 16-bit, 32-bit, and 64-bit signed and unsigned integer SIMD computation
- 8-bit or 16-bit polynomial computation for single-bit coefficients

The following operations are available:

- Addition and subtraction
- Multiplication with optional accumulation (MAC)
- Maximum or minimum value driven lane selection operations
- Inverse square root approximation
- Comprehensive data-structure load instructions, including register-bank-resident table lookup

Related Information

http://infocenter.arm.com/

For more information about the Cortex-A9 NEON MPE, refer to the Cortex-A9 NEON™ Media Processing Engine Technical Reference Manual, which you can download from the ARM Infocenter website.

Memory Management Unit

The MMU is used in conjunction with the L1 and L2 caches to translate virtual addresses used by software to physical addresses used by hardware. Each processor has a private MMU.

TLBs Supported By the MMU

TLB Type	Memory Type	Number of Entries	Associativity
Micro TLB	Instruction	32	Fully associative
Micro TLB	Data	32	Fully associative
Main TLB	Instruction and Data	128	Two-way associative

TLB Features

The main TLB has the following features:

- Lockable entries using the lock-by-entry model
- Supports hardware page table walks to perform look-ups in the L1 data cache

The MPU address map is divided into the following regions:

- The boot region
- The SDRAM region
- The FPGA slaves region
- The HPS peripherals region

Note: The `SMP` bit in the `ACTLR` register must be set before enabling the MMU.

Related Information

http://infocenter.arm.com/
For more information about the MMU, refer to the *Memory Management Unit* chapter of the *Cortex-A9 Technical Reference Manual*, available on the ARM Infocenter website.

The Boot Region

The boot region is 1 MB in size, based at address 0. After power-on, or after reset of the system interconnect, the boot region is occupied by the boot ROM, allowing the Cortex-A9 MPCore to boot. Although the boot region size is 1 MB, accesses beyond 64 KB are illegal because the boot ROM is only 64 KB.

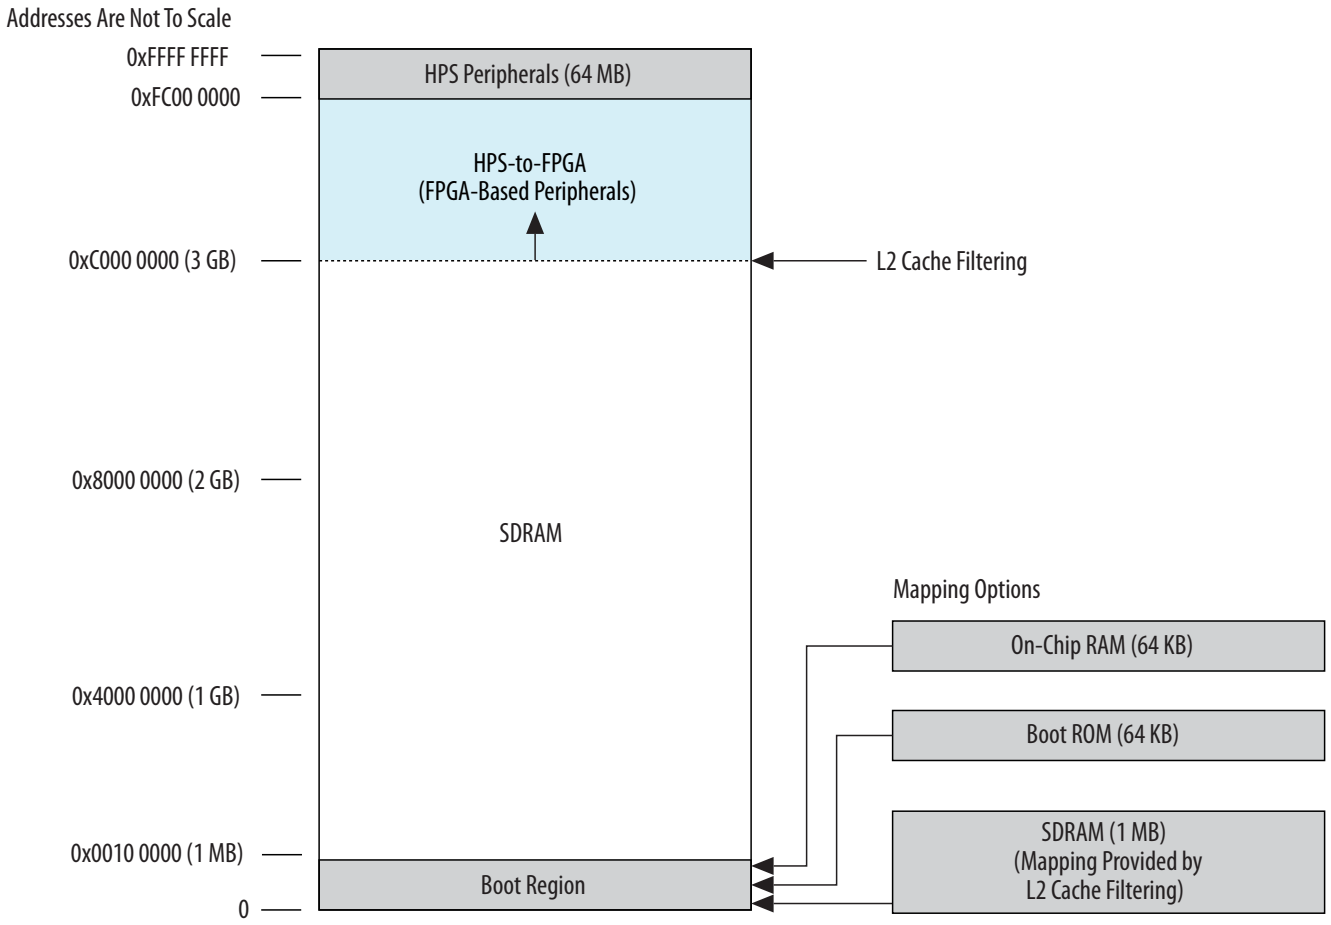
The 1 MB boot region can be subsequently remapped to the bottom 1 MB of SDRAM region by adjusting the L2 cache address filter.

Note: Alternatively, the boot region can be mapped to the 64 KB on-chip RAM.

Related Information

- **The SDRAM Region** on page 9-11
- **System Interconnect** on page 7-1

Boot ROM Mapping



The SDRAM Region

The SDRAM region starts at address `0x100000` (1 MB). The top of the region is determined by the L2 cache filter.

The L2 cache contains a filtering mechanism that routes accesses to the SDRAM and system interconnect. The filter defines a filter range with start and end addresses. Any access within this filter range is routed to the SDRAM subsystem. Accesses outside of this filter range are routed to the system interconnect.

The start and end addresses are specified in the following register fields:

- `reg12_addr_filtering_start.address_filtering_start`
- `reg12_address_filtering_end.address_filtering_end`

To remap the lower 1MB of SDRAM into the boot region, set the filter start address to `0x0` to ensure accesses between `0x0` and `0xFFFFF` are routed to the SDRAM. Independently, you can set the filter end address in 1 MB increments above `0xC0000000` to extend the upper bounds of the SDRAM region. However, you achieve this extended range at the expense of the FPGA peripheral address span. Depending on the address filter settings in the L2 cache, the top of the SDRAM region can range from `0xBFFFFFFF` to `0xFBFFFFFF`.

Related Information

L2 Cache on page 9-53

The FPGA Slaves Region

The Cortex-A9 MPU subsystem supports the variable-sized FPGA slaves region to communicate with FPGA-based peripherals. This region can start as low as `0xC0000000`, depending on the L2 cache filter settings. The top of the FPGA slaves region is located at `0xFBFFFFFF`. As a result, the size of the FPGA slaves region can range from 0 to `0x3F000000` bytes.

The HPS Peripherals Region

The HPS peripherals region is the top 64 MB in the address space, starting at `0xFC000000` and extending to `0xFFFFFFFF`. The HPS peripherals region is always allocated to the HPS dedicated peripherals for the Altera Cortex-A9 MPU subsystem.

Performance Monitoring Unit

Each Cortex-A9 processor has a Performance Monitoring Unit (PMU). The PMU supports 58 events to gather statistics on the operation of the processor and memory system. Six counters in the PMU accumulate the events in real time. The PMU counters are accessible either from the processor itself, using the Coprocessor 14 (CP14) interface, or from an external debugger. The events are also supplied to the PTM and can be used for trigger or trace.

Related Information

For more information about the PMU, refer to the *Performance Monitoring Unit* chapter of the *Cortex-A9 Technical Reference Manual*, available on the ARM Infocenter website.

MPCore Timers

There is one interval timer and one watchdog timer for each processor.

Functional Description

Each timer is private, meaning that only its associated processor can access it. If the watchdog timer is not needed, it can be configured as a second interval timer.

Each private interval and watchdog timer has the following features:

- A 32-bit counter that optionally generates an interrupt when it reaches zero
- Configurable starting values for the counter
- An eight-bit prescaler value to qualify the clock period

Implementation Details

The timers are configurable to either single-shot or auto-reload mode. The timer blocks are clocked by `mpu_periph_clk` running at ¼ the rate of the `mpu_clk`.

Related Information

http://infocenter.arm.com/
For more information about private timers, refer to "About the private timer and watchdog blocks" in the *Global timer, Private timers, and Watchdog registers* chapter of the *Cortex-A9 MPCore Technical Reference Manual*, available on the ARM Infocenter website.

Generic Interrupt Controller

Functional Description

The PL390 Generic Interrupt Controller (GIC) supports up to 180 interrupt sources, including dedicated peripherals and IP implemented in the FPGA fabric. In a dual-core system, the GIC is shared by both Cortex-A9 processors. Each processor also has 16 banked software-generated interrupts and 16 banked private peripheral interrupts, which occupy GIC interrupt numbers 0 to 31.

Implementation Details

The configuration and control for the GIC is memory-mapped and accessed through the SCU. The GIC are clocked by `mpu_periph_clk`, running at ¼ the rate of `mpu_clk`.

Global Timer

The MPU features a global 64-bit, auto-incrementing timer, which is primarily used by the operating system.

Functional Description

The global timer is accessible by the processors using memory-mapped access through the SCU. The global timer has the following features:

- 64-bit incrementing counter with an auto-incrementing feature. It continues incrementing after sending interrupts.
- Memory-mapped in the private memory region.
- Accessed at reset in Secure State only. It can only be set once, but secure code can read it at any time.
- Accessible to both Cortex-A9 processors in the MPCore.
- Clocked by `mpu_periph_clk`, running at ¼ the rate of `mpu_clk`.

Implementation Details

Each Cortex-A9 processor has a private 64-bit comparator that generates a private interrupt when the counter reaches the specified value. Each Cortex-A9 processor uses the banked ID, ID27, for this interrupt. ID27 is sent to the GIC as a Private Peripheral Interrupt (PPI).

The global timer is clocked by mpu_periph_clk, running at ¼ the rate of mpu_clk.

Related Information

http://infocenter.arm.com/
For more information about the global timer, refer to "About the Global Timer" in the *Global timer, Private timers, and Watchdog registers* chapter of the Cortex-A9 MPCore Technical Reference Manual, available on the ARM Infocenter website.

Snoop Control Unit

The SCU manages data traffic for the Cortex-A9 processors and the memory system, including the L2 cache. In a multi-master system, the processors and other masters can operate on shared data. The SCU ensures that each processor operates on the most up-to-date copy of data, maintaining cache coherency.

Functional Description

The SCU is used to connect the Cortex-A9 processors and the ACP to the L2 cache controller. The SCU performs the following functions:

- When the processors are set to SMP mode, the SCU maintains data cache coherency between the processors.

  Note: The SCU does not maintain coherency of the instruction caches.
- Initiates L2 cache memory accesses
- Arbitrates between processors requesting L2 access
- Manages ACP access with cache coherency capabilities.

Related Information

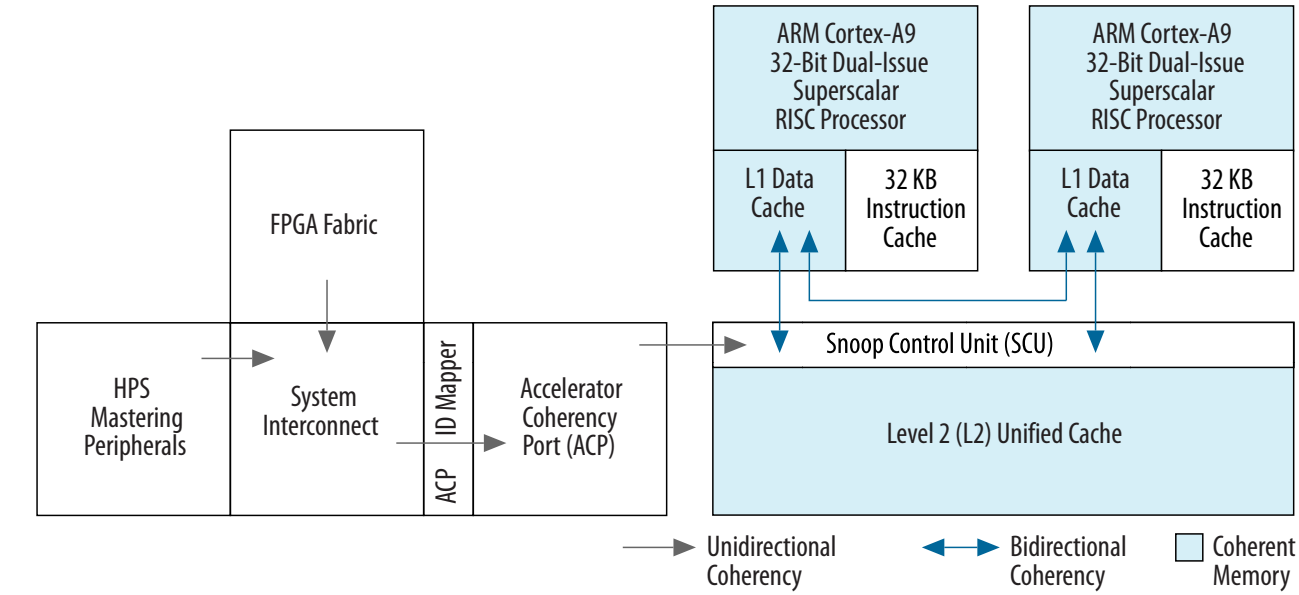
For more information about the SCU, refer to the *Snoop Control Unit* chapter of the *Cortex-A9 MPCore Technical Reference Manual*, available on the ARM Infocenter website.

Coherent Memory, Snoop Control Unit, and Accelerator Coherency Port

The SCU in a dual-processor system, illustrating the flow of data among the L1 data caches and the SCU.



Related Information

Accelerator Coherency Port on page 9-26

Implementation Details

When the processor writes to any coherent memory location, the SCU ensures that the relevant data is coherent (updated, tagged, or invalidated). Similarly, the SCU monitors read operations from a coherent memory location. If the required data is already stored within the other processor's L1 cache, the data is returned directly to the requesting processor. If the data is not in L1 cache, the SCU issues a read to the L2 cache. If the data is not in the L2 cache memory, the read is finally forwarded to main memory. The primary goal is to minimize power consumption and maximize overall memory performance.

The SCU maintains bidirectional coherency between the L1 data caches belonging to the processors. When one processor writes to a location in its L1 cache, if the same location is cached in the other L1 cache, the SCU updates it.

Non-coherent data passes through as a standard read or write operation.

The SCU also arbitrates between the Cortex-A9 processors if both attempt simultaneous access to the L2 cache, and manages accesses from the ACP.

Accelerator Coherency Port

The ACP allows master peripherals—including FPGA-based peripherals—to maintain data coherency with the Cortex-A9 MPCore processors and the SCU. Dedicated master peripherals in the HPS, and those built in FPGA logic, access the coherent memory through the ACP ID mapper and the ACP.

The ACP port allows one-way coherency. One-way coherency allows an external ACP master to see the coherent memory of the Cortex-A9 processors but does not allow the Cortex-A9 processors to see memory changes outside of the cache.

A master on the ACP port can read coherent memory directly from the L1 and L2 caches, but cannot write directly to the L1 cache. The possible ACP master read and write scenarios are as follows:

- ACP master read with coherent data in the L1 cache: The ACP gets data directly from the L1 cache and the read is interleaved with a processor access to the L1 cache.
- ACP master read with coherent data in L2 cache: The ACP request is queued in the SCU and the transaction is sent to the L2 cache.
- ACP master read with coherent data not in L1 or L2 cache: Depending on the previous state of the data, the L1 or L2 cache may request the data from the L3 system interconnect. The ACP is stalled until data is available, however ACP support of multiple outstanding transactions minimizes bottlenecks.
- ACP master write with coherent data in the L1 cache: The L1 cache data is marked as invalid in the Cortex-A9 MPU and the line is evicted from the L1 cache and sent to L2 memory.. The ACP write data is scheduled in the SCU and is eventually written to the L2 cache. Later, when the Cortex-A9 processor accesses the same memory location, a cache miss in the L1 occurs.
- ACP master write, with coherent data in the L2 cache: The ACP write is scheduled in the SCU and then is written into the L2 cache.
- ACP master write, with coherent data not in L1 or L2 cache: ACP write is scheduled.

Note: The entire 4 GB address space can be accessed coherently through the ACP through a 1 GB coherent window implemented through the ACP ID mapper.

AxUSER and AxCACHE Attributes

ARUSER[0] and AWUSER[0] Bits

The table below shows how the AxUSER[0] bit determines whether a request is shared or non-shared. ARUSER[0] applies to read transactions, and AWUSER[0] applies to write transactions.

Table 9-4: ARUSER[0] or AWUSER[0] Sideband Signal Information

ARUSER[0] or AWUSER[0]	Sideband Signal Information
1	Shared request
0	Non-shared request

Other AxUSER bits from the ACP are not interpreted by the SCU but are forwarded to the L2 cache.

Note: Except for the FPGA-to-HPS masters, the ACP ID mapper provides the AxUSER signals for all other masters.

ARCACHE[4:0] and AWCACHE[4:0] Bits

The Cortex-A9 MPU only interprets ARCACHE[1] and AWCACHE[1] from ACP requests. All other attributes are forwarded to the L2 cache. AxCACHE[1] is used in combination with AxUSER[0] to detect a coherent access. If AxCACHE[1]=0x1, (normal memory) and AxUSER[0]=0x1, then the access is considered coherent. All ACP requests with AxCACHE[1]=0x0 or AxUSER[0]=0x0 are seen as non-coherent requests.

Table 9-5: ARUSER[0] or AWUSER[0] Sideband Signal Information

ARCACHE[1] or AWCACHE[1]	ARUSER[0] or AWUSER[0]	Access Type
1	1	Coherent request
0	0	Non-coherent request

Cache Coherency for ACP Shared Requests

When a shared access is received on the ACP, caches are checked for coherency of the requested address. A shared access occurs when two masters access the same memory space.

This coherency check is performed by the SCU. If a cache hit occurs during a write access, the affected cache lines are cleaned and invalidated. This event may cause an eviction from the L1 cache to be sent to L2 memory if the L1 cache line is dirty. Once the invalidation and possible eviction is completed, the ACP write request is written to L2 memory. If an eviction was executed from L1 cache, then two consecutive writes to L2 memory occur over the AXI bus: the write from the eviction and the write from the ACP.

For a cache hit during a read access, the L1 cache line is provided by the CPU and is returned to the ACP.

For a cache miss during a write access, the invalidation is considered as complete and the ACP request is sent to L2 memory.

For a cache miss during a read access, the request is forwarded to L2 memory, which returns the data directly to the ACP.

Note: Shared write requests are always transferred to the L2 memory once the cache line is potentially clean and invalidated in the L1 cache memory. Reads are observed on the L2 only if they miss in the L1 cache.

Burst Sizes and Byte Strobes

The ACP improves system performance for hardware accelerators in the FPGA fabric. However, in order to achieve high levels of performance, you must use the one of the optimized burst types. Other burst configurations have significantly lower performance.

Recommended Burst Types

Table 9-6: Recommended Burst Types for Optimized Bursts

Burst Type	Beats	Width (Bits)	Address Type	Byte Strobes
Wrapping	4	64	64-bit aligned	Asserted
Incrementing	4	64	32-bit aligned	Asserted

Note: If the slave port of the FPGA-to-HPS bridge is not 64 bits wide, you must supply bursts to the FPGA-to-HPS bridge that are upsized or downsized to the burst types above. For example, if the slave data width of the FPGA-to-HPS bridge is 32 bits, then bursts of eight beats by 32 bits are required to access the ACP efficiently.

Note: If the address and burst size of the transaction to the ACP matches either of the conditions shown in the table "Recommended Burst Types for Optimized Bursts", the logic in the MPU assumes the transaction has all its byte strobes set. If the byte strobes are not all set, then the write does not

actually overwrite all the bytes in the word. Instead, the cache assumes the whole cache line is valid. If this line is dirty (and therefore gets written out to SDRAM), data corruption might occur.

In addition to optimizing performance, using a 64-bit access width will allow you to use ECC. ECC is only supported for 64-bit accesses that are 64-bit aligned..

Related Information

ECC Support on page 9-55

Configuration for ACP Use

To use the ACP for coherent accesses, the following configurations apply:

ACP master configurations must be as follows::

- The master module must target the ACP in physical memory (address 0x80000000 to 0xC0000000)
- For coherent ACP read accesses, the AXI bits must be programmed as follows:
  - Match the `ARCACHE` attributes to the configured MMU page table attributes.
  - ACP `ARCACHE[1]` must be set to 0x1
  - ACP `ARUSER[0]` must be set to 0x1
- For coherent ACP write accesses, the AXI bits must be programmed as follows:
  - Match the `AWCACHE` attributes to the configured MMU page table attributes.
  - ACP `AWCACHE[1]` must be set to 0x1
  - ACP `AWUSER[0]` must be set to 0x1
- If FPGA masters are used in ACP accesses, then the `AxCACHE` and `AxUSER` bits are set directly by the signals from the FPGA soft IP.
- If an HPS peripheral uses the ACP for coherent master accesses, then the `AxCACHE` properties must be configured in the corresponding System Manager register for that peripheral and the ACP ID mapper must be configured for the appropriate `AxUSER` properties.

The Cortex-A9 MPCore configuration for ACP use should be as follows:

- The Snoop Control Unit must be enabled (by setting the SCU enable bit in the SCU Control Register at 0xFFFEC000).
- Coherent memory must be marked cacheable and shareable.
- The `SMP` bit of the `ACTLR` register must be set in the Cortex-A9 processor that shares data over the ACP.

To achieve maximum performance on the ACP, avoid switching from shared to non-shared requests and vice-versa. When a shared request is latched in the ACP and there are non-shared requests still pending, the non-shared requests must be completed before the shared request can proceed.

Exclusive and Locked Accesses

The ACP does not support exclusive accesses to coherent memory. Exclusive accesses to non-coherent memory can be generated, however, it is important that the exclusive access transaction is not affected by the upsizing and downsizing logic of the FPGA-to-HPS bridge or the system interconnect. If the exclusive access is broken into multiple transactions due to the sizing logic, the exclusive access bit is cleared by the bridge or interconnect and the exclusive access fails.

Note: Altera recommends that exclusive accesses bypass the ACP altogether, either through the 32-bit slave port of the SDRAM controller connected directly to the system interconnect or through the FPGA-to-SDRAM interface.

The ACP ID mapper does not support locked accesses. To ensure mutually exclusive access to shared data, use the exclusive access support built into the SDRAM controller.

Related Information

SDRAM Controller Subsystem on page 11-1
For more information about the exclusive access support of the SDRAM controller subsystem, refer to the *SDRAM Controller Subsystem* chapter.

ACP ID Mapper

The ACP ID mapper is situated between the level 3 (L3) interconnect and the MPU subsystem ACP slave. It is responsible for mapping 12-bit Advanced Microcontroller Bus Architecture (AMBA®) Advanced eXtensible Interface (AXI™) IDs (input IDs) from the system interconnect to 3-bit AXI IDs (output IDs) supported by the ACP slave port.

The ACP ID mapper also implements a 1 GB coherent window into the 4 GB MPCore address space.

Functional Description

The ACP slave supports up to six masters. However, custom peripherals implemented in the FPGA fabric can have a larger number of masters that need to access the ACP slave. The ACP ID mapper allows these masters to access the ACP.

The ACP ID mapper resides between the interconnect and the ACP slave of the MPU subsystem. It has the following characteristics:

- Support for up to six concurrent ID mappings
- 1 GB coherent window into 4 GB MPCore address space
- Remaps the 5-bit user sideband signals used by the Snoop Control Unit (SCU) and L2 cache

Related Information

http://infocenter.arm.com/
For more information about AXI user sideband signals, refer to the CoreLink Level 2 Cache Controller L2C-310 Technical Reference Manual, available from the ARM Infocenter website.

Implementation Details

The ACP is accessed by masters that require access to coherent memory. The ACP slave port can be accessed by the master peripherals of the L3 interconnect, as well as by masters implemented in the FPGA fabric (via the FPGA-to-HPS bridge).

The ACP ID mapper supports the following ID mapping modes:

- Dynamic mapping
- Fixed mapping

Software can select the ID mapping on a per-ID basis. For input IDs that are configured for fixed mapping, there is a one-to-one mapping from input IDs to output IDs. When an input ID is configured for dynamic mapping, it is automatically mapped to an available output ID. The dynamic mode is more flexible because the hardware handles the mapping. The hardware mapping allows you to use one output ID for more than one input ID. Output IDs are assigned to input IDs on a first-come, first-served basis.

Out of the total of eight output IDs, only six are available to masters of the system interconnect. The first two output IDs (0 and 1) are dedicated to the Cortex-A9 processor cores in the MPU subsystem, leaving the last six output IDs (2-7) available to the ACP ID mapper. Output IDs 2-6 support fixed and dynamic modes of operation while output ID 7 supports dynamic only.

The operating modes are programmable through accesses to the control and status registers in the ACP ID mapper. At reset time, the ACP ID mapper defaults to dynamic ID mapping for all output IDs except ID 2, which resets to a fixed mapping for the Debug Access Port (DAP) input ID.

ID Intended Usage

Table 9-7 summarizes the expected usage of the 3-bit output IDs, and their settings at reset.

Table 9-7: ID Intended Usage

Output ID	Reset State	Intended Use
7	Dynamic	Dynamic mapping only
6	Dynamic	Fixed or dynamic, programmed by software.
5		
4		
3		
2	Statistically assigned to DAP (ID 0x005)	Assigned to the input ID of the DAP at reset. After reset, can be either fixed or dynamic, programmed by software.
1	—	Not used by the ACP ID Mapper because these IDs are assigned to CPU1 and CPU0. ID=1 is for CPU1 and ID=0 is for CPU0.
0		

AXI User Sideband Override

For masters that cannot drive the AXI user sideband signal of incoming transactions, the ACP ID mapper can control overriding this signal. The ACP ID mapper can also control which 1 GB coherent window into memory is accessed by masters of the system interconnect. Each fixed mapping can be assigned a different user sideband signal and memory window to allow specific settings for different masters. All dynamic mappings share a common user sideband signal and memory window setting.

Transaction Capabilities

At any one time, the ACP ID mapper can accept and issue up to 15 transactions per ID mapping. Read and write ID mappings are managed in separate lists, allowing more unique input IDs to be remapped at any given time. If a master issues a series of reads and writes with the same input ID, there are no ordering restrictions.

Because there are only six output IDs available, there can be no more than six read and six write transactions with unique IDs in progress at any one time. The write acceptance of the ACP slave is five transactions, and the read acceptance is 13 transactions. Only four coherent read transactions per ID mapping can be outstanding at one time.

Dynamic Mapping Mode

In dynamic mode, every unique input ID that is received from the L3 master port is assigned to an unused output ID. The new output ID is applied to the transaction as it is issued to the ACP slave of the SCU. Any transaction that arrives to the ACP ID mapper with an input ID that matches an already-in-progress transaction is mapped to the same output ID. Once all transactions on an ID mapping have completed, that output ID is released and can be used again for other input IDs.

Fixed Mapping Mode

In fixed mode, output IDs 2 through 6 can be assigned by software to a specific 12-bit input ID. This ability makes it possible to use the lock-by-master feature of the L2 cache controller, because the input transaction ID from the master is always assigned to a specific output ID. ID 7 is not available for fixed mapping because it is reserved for dynamic mode only to avoid system deadlocks.

The ACP ID mapper can control the behavior of read and write virtual fixed ID mappings through the `vid*rd` and `vid*wr` registers. By programming the `force` bit to 0x1 in the `vid*rd` and `vid*wr` registers, the 12-bit `mid` field is forced to a specific 3-bit virtual ID. The `mid` field can be different between the read and write AXI Master Mapping registers. When these registers are programmed, hardware examines the request, and only applies the change when safe to do so, which is when there are no outstanding transactions with the output ID. When the change is applied, the status register is updated. Software should check that the change has actually taken place by polling the corresponding status register.

HPS Peripheral Master Input IDs

The following table identifies the ID that must be programmed in the `mid` field of the `vid*rd` and `vid*wr` registers, if an HPS master requires a fixed ACP mapping. The first column of the table gives the generic ID encoding, where the "x"s represent bits that change based on if the `vid*rd` or `vid*wr` register is being configured.

Table 9-8: HPS Peripheral Master Input IDs

The input IDs issued from the interconnect for each HPS peripheral master that can access the ACP ID mapper

Interconnect Master	ID [19]	vid*rd.mid	vid*wr.mid
DMA	0000 0xxx x001	"x" should indicate the total number of DMA channels. When the DMA performs an ACP read, the DMA controller signals the x values to be the same number as the number of DMA channels that the DMA controller provides. For example, if the DMA controller provides eight DMA channels, the x values must be set to 4'b1000.	"x" should indicate the number of the channel performing the write. When a DMA channel performs and an ACP write, the DMA controller signals the x values to be the same number as the DMA channel. For example, when DMA channel 5 performs a DMA store operation, the DMA Controller sets the x values to 4'b0101.
EMAC0	1000 0000 x001	1000 0000 1001	1000 0000 0001
EMAC1	1000 0000 x010	1000 00001 1001	1000 0001 0001

This section lists the ACP ID Mapper register address map and describes the registers.

Control of the AXI User Sideband Signals

The ACP ID mapper module allows control of the AXI user sideband signal values. Not all masters drive these signals, so the ACP ID mapper makes it possible to drive the 5-bit user sideband signal with either a default value (in dynamic mode) or specific values (in fixed mode). The sideband signals are controlled through the ACP port. Sideband signals `AWUSER[4:1]` convey the inner cache attributes and `AWUSER[0]` determines whether the transaction is a shared cache access.

There are registers available to configure the default values of the user sideband signals for all transactions, and fixed values of these signals for particular transactions in fixed mapping mode. In dynamic mode, the user sideband signals of incoming transactions are mapped with the default values stored in the register. In fixed mapping mode, the input ID of the transaction is mapped to the 3-bit output ID and the user sideband signals of the transaction are mapped with the values stored in the register that corresponds to the output ID. One important exception, however, is that the ACP ID mapper always allows user sideband signals from the FPGA-to-HPS bridge to pass through to the ACP regardless of the user sideband value associated with the ID.

Note: For coherent, cacheable reads or writes, the `user` field of the `vid*rd` and `vid*wr` registers must be set to 5'b11111 (coherent write back, write allocate inner cache attribute). This configuration ensures that the inner cache policy matches the policy used for cacheable data written by the processor.

Memory Region Remap

The ACP ID mapper has 1 GB of address space, which is by default a view into the bottom 1 GB of SDRAM. The mapper also allows transactions to be routed to different 1 GB-sized memory regions, called pages, in both dynamic and fixed modes. The two most significant bits of incoming 32-bit AXI address signals are replaced with the 2-bit user-configured address page decode information. The page decoder uses the values shown in **Table 9-9**.

Table 9-9: Page Decoder Values

Page	Address Range
0	`0x00000000–0x3FFFFFFF`
1	`0x40000000–0x7FFFFFFF`
2	`0x80000000–0xBFFFFFFF`
3	`0xC0000000–0xFFFFFFFF`

With this page decode information, a master can read or write to any 1 GB region of the 4 GB memory space while maintaining cache coherency with the MPU subsystem.

Using this feature, a debugger can have a coherent view into main memory, without having to stop the processor. For example, at reset the DAP input ID (0x001) is mapped to output ID 2, so the debugger can vary the 1 GB window that the DAP accesses without affecting any other traffic flow to the ACP.

L2 Cache

The MPU subsystem includes a secondary 512 KB L2 shared, unified cache memory.

Functional Description

The L2 cache is much larger than the L1 cache. The L2 cache has significantly lower latency than external memory. The L2 cache is up to eight-way associative, configurable down to one-way (direct mapped). Like the L1 cache, the L2 cache can be locked by cache line, locked by way, or locked by master (CPU and ACP masters).

The L2 cache implements error correction codes (ECCs) and ECC error reporting. The cache can report a number of events to the processor and operating system.

Related Information

Cortex-A9 MPU Subsystem Register Implementation on page 9-61
For more information regarding the L2 Cache Controller Address Map, refer to the *Cortex-A9 MPU Subsystem Register Implementation* section.

Cache Controller Configuration

The L2 cache consists of the ARM L2C-310 L2 cache controller configured as follows:

- 512 KB total memory
- Eight-way associativity
- Physically addressed, physically tagged
- Line length of 32 bytes
- Critical first word linefills
- Support for all AXI cache modes
  - Write-through
  - Write-back
  - Read allocate
  - Write allocate
  - Read and write allocate
- Single event upset (SEU) protection
  - Parity on Tag RAM
  - ECC on L2 Data RAM
- Two slave ports mastered by the SCU
- Two master ports connected to the following slave ports:
  - SDRAM controller, 64-bit slave port width
  - L3 interconnect, 64-bit slave port width
- Cache lockdown capabilities as follows:
  - Line lockdown
  - Lockdown by way
  - Lockdown by master (both processors and ACP masters)
- TrustZone support
- Cache event monitoring

Parity Error Handling

If a parity error occurs on tag or data RAM during AXI read transactions, a SLVERR response is reported through the event bus and interrupt signals. If a parity error occurs on tag or data RAM during AXI write transactions, a SLVERR response is reported back through a SLVERRINTR interrupt signal. For cache

maintenance operations, if a parity error occurs on tag or data RAM, the error is reported back through the interrupt lines only. In addition, the L2 Cache cannot refill a line from external memory due to a parity error.

  For more information about AXI user sideband signals, refer to the CoreLink Level 2 Cache Controller L2C-310 Technical Reference Manual, which you can download from the ARM Infocenter website.

L2 Cache Address Filtering

The L2 cache can access either the system interconnect fabric or the SDRAM. The L2 cache address filtering determines how much address space is allocated to the HPS-to-FPGA bridge and how much is allocated to SDRAM, depending on the configuration of the memory management unit.

Related Information

- **Cortex-A9 MPU Subsystem with System Interconnect** on page 9-2
- **Memory Management Unit** on page 9-9
  Information about how the address space is set based on L2 cache address filtering.

Cache Latency

Latency for cache hits and misses varies.

The latency for an L1 cache hit is 1 clock. The latency for an L1 cache miss and L2 cache hit is 6 clocks best case. Latency in the L2 cache can vary depending on other operations in the L2. Parity and ECC settings have no effect on latency. A single-bit ECC error is corrected during the L2 read, but is not re-written to the L2 RAM.

ECC Support

The L2 cache has the option of using ECCs to protect against SEU errors in the cache RAM.

Enabling ECCs does not affect the performance of the L2 cache. The ECC bits are calculated only for writes to the data RAM that are 64 bits wide (8 bytes, or one-quarter of the cache line length). The ECC logic does not perform a read-modify-write when calculating the ECC bits.

The ECC protection bits are not valid in the following cases:

- Data is written that is not 64-bit aligned in memory
- Data is written that is less than 64 bits in width

In these cases the Byte Write Error interrupt is asserted. Cache data is still written when such an error occurs. However, the ECC error detection and correction continues to function. Therefore, the cache data is likely to be incorrect on subsequent reads.

To use ECCs, the software and system must meet the following requirements:

- L1 and L2 cache must be configured as write-back and write-allocate for any cacheable memory region
- Level 3 interconnect masters using the ACP must only perform the following types of data writes:
  - 64-bit aligned in memory
  - 64-bit wide accesses

  Note that system interconnect masters can include masters in the FPGA accessing the FPGA-to-HPS bridge.

If a correctable ECC error occurs, the ECC corrects the read data in parallel to asserting a correctable error signal on the AXI bus. If an uncorrectable error occurs in the L2 cache, the uncorrected data remains in the L2 cache and an AXI slave error (SLVERR) is sent to the L1 memory system. In addition, interrupts can be enabled for correctable and uncorrectable ECC errors through the GIC.

Related Information

System Manager on page 5-1
For more information about SEU errors, refer to the *System Manager* chapter.

Implementation Details

The following table shows the parameter settings for the cache controller.

Table 9-10: Cache Controller Configuration

Feature	Meaning
Cache way size	64 KB
Number of cache ways	8 ways
Tag RAM write latency	1
Tag RAM read latency	1
Tag RAM setup latency	1
Data RAM write latency	1
Data RAM read latency	2
Data RAM setup latency	1
Parity logic	Parity logic enabled
Lockdown by master	Lockdown by master enabled
Lockdown by line	Lockdown by line enabled
AXI ID width on slave ports	6 AXI ID bits on slave ports

Feature	Meaning
Address filtering	Address filtering logic enabled
Speculative read	Logic for supporting speculative read enabled
Presence of ARUSERMx and AWUSERMx sideband signals	Sideband signals enabled

Related Information

http://infocenter.arm.com/
For further information about cache controller configurable options, refer to the CoreLink Level 2 Cache Controller L2C-310 Technical Reference Manual, available on the ARM Infocenter website.

L2 Cache Lockdown Capabilities

The L2 cache has three methods to lock data in the cache RAMs:

- Lockdown by line—Used to lock lines in the cache. This is commonly used for loading critical sections of software into the cache temporarily.
- Lockdown by way—Allows any or all of the eight cache ways to be locked. This is commonly used for loading critical data or code into the cache.
- Lockdown by master—Allows cache ways to be dedicated to a single master port. This allows a large cache to look like smaller caches to multiple master ports. The L2 cache can be mastered by CPU0, CPU1, or the six ACP masters, for a total of eight possible master ports.

Related Information

For more information about L2 cache lockdown capabilities, refer to "Cache operation" in the *Functional Overview* chapter of the *CoreLink Level 2 Cache Controller L2C-310 Technical Reference Manual*, available on the ARM Infocenter website.

L2 Cache Event Monitoring

The L2 cache supports the built-in cache event monitoring signals shown in the table below. The L2 cache can count two of the events at any one time.

Table 9-11: L2 Cache Events

Event	Description
`CO`	Eviction (cast out) of a line from the L2 cache.
`DRHIT`	Data read hit in the L2 cache.
`DRREQ`	Data read lookup to the L2 cache. Subsequently results in a hit or miss.
`DWHIT`	Data write hit in the L2 cache.

Event	Description
DWREQ	Data write lookup to the L2 cache. Subsequently results in a hit or miss.
DWTREQ	Data write lookup to the L2 cache with write-through attribute. Subsequently results in a hit or miss.
EPFALLOC	Prefetch hint allocated into the L2 cache.
EPFHIT	Prefetch hint hits in the L2 cache.
EPFRCVDS0	Prefetch hint received by slave port S0.
EPFRCVDS1	Prefetch hint received by slave port S1.
IPFALLOC	Allocation of a prefetch generated by L2 cache controller into the L2 cache.
IRHIT	Instruction read hit in the L2 cache.
IRREQ	Instruction read lookup to the L2 cache. Subsequently results in a hit or miss.
SPNIDEN	Secure privileged non-invasive debug enable.
SRCONFS0	Speculative read confirmed in slave port S0.
SRCONFS1	Speculative read confirmed in slave port S1.
SRRCVDS0	Speculative read received by slave port S0.
SRRCVDS1	Speculative read received by slave port S1.
WA	Allocation into the L2 cache caused by a write (with write-allocate attribute) miss.

In addition, the L2 cache events can be captured and timestamped using dedicated debugging circuitry.

Related Information

http://infocenter.arm.com/

For more information about L2 event capture, refer to the *Debug* chapter of the Cortex-A9 MPCore Technical Reference Manual, available on the ARM Infocenter website.

CPU Prefetch

The Cortex®-A9 performs instruction and data prefetches regardless of the state of the MMU.

A prefetch occurs when any address that is 4 KB above the current instruction pointer is accessed. The system has been designed to ensure that the system bus does not lock on prefetches. Any prefetches to unmapped memory space produce a decode error on the system interconnect.

Debugging Modules

The MPU subsystem includes debugging resources through ARM CoreSight on-chip debugging and trace. The following functionality is included:

- Individual program trace for each processor
- Event trace for the Cortex-A9 MPCore
- Cross triggering between processors and other HPS debugging features

Program Trace

Each processor has an independent PTM that provides real-time instruction flow trace. The PTM is compatible with a number of third-party debugging tools.

The PTM provides trace data in a highly compressed format. The trace data includes tags for specific points in the program execution flow, called waypoints. Waypoints are specific events or changes in the program flow.

The PTM recognizes and tags the waypoints listed in **Table 9-12**.

Table 9-12: Waypoints Supported by the PTM

Type	Additional Waypoint Information
Indirect branches	Target address and condition code
Direct branches	Condition code
Instruction barrier instructions	—
Exceptions	Location where the exception occurred
Changes in processor instruction set state	—
Changes in processor security state	—
Context ID changes	—
Entry to and return from debug state when Halting debug mode is enabled	—

The PTM optionally provides additional information for waypoints, including the following.

- Processor cycle count between waypoints
- Global timestamp values
- Target addresses for direct branches

Related Information

- **CoreSight Debug and Trace** on page 10-1
- **http://infocenter.arm.com/**
  For more information about the PTM, refer to the CoreSight PTM-A9 Technical Reference Manual, available on the ARM Infocenter website.

Event Trace

Events from each processor can be used as inputs to the PTM. The PTM can use these events as trace and trigger conditions.

Related Information

- **Performance Monitoring Unit** on page 9-12
- **http://infocenter.arm.com/**
  For more information about the trigger and trace capabilities, refer to the CoreSight PTM-A9 Technical Reference Manual, Revision r1p0, available on the ARM Infocenter website.

Cross-Triggering

The PTM can export trigger events and perform actions on trigger inputs. The cross-trigger signals interface with other HPS debugging components including the FPGA fabric. Also, a breakpoint in one processor can trigger a break in the other.

Related Information

CoreSight Debug and Trace on page 10-1
For detailed information about cross-triggering and about debugging hardware in the MPU, refer to the *CoreSight Debug and Trace* chapter.

Clocks

Four synchronous clocks and two debug clocks are provided to the MPU subsystem.

Table 9-13: MPU Subsystem Clocks

System Clock Name	Use
`mpu_clk`	Main clock for the MPU subsystem
`mpu_periph_clk`	Clock for peripherals inside the MPU subsystem
`mpu_l2_ram_clk`	Clock for the L2 cache and Accelerator Coherency Port (ACP) ID mapper

System Clock Name	Use
l4_mp_clk	Clock for the ACP ID mapper control slave
dbg_at_clk	Trace bus clock
dbg_clk	Debug clock

Related Information

Clock Manager on page 2-1

Cortex-A9 MPU Subsystem Register Implementation

The following configurations are available through registers in the Cortex-A9 subsystem:

- All processor-related controls, including the MMU and L1 caches, are controlled using the Coprocessor 15 (CP15) registers of each individual processor.
- All SCU registers, including control for the timers and GIC, are memory mapped.
- All L2 cache registers are memory-mapped.

Related Information

http://infocenter.arm.com/

For detailed definitions of the registers for the Altera Cortex-A9 MPU subsystem, refer to the Cortex-A9 MPCore Technical Reference Manual, Revision r3p0 and the CoreLink Level 2 Cache Controller L2C-310 Technical Reference Manual, Revision r3p3, available on the ARM Infocenter website.

Cortex-A9 MPU Subsystem Address Map

The Cortex®-A9 MPU subsystem registers reside within the address range from 0xFFFEC000 to 0xFFFEEFFF.

Table 9-14: MPU Module Address Range

Module Instance	Start Address	End Address
MPU	0xFFFEC000	0xFFFEEFFF

Table 9-15: Cortex-A9 MPU Submodule Register Space

Submodule Instance	Description	Start Address	End Address
SCU	This address space is allocated for the Snoop Control Unit registers.	0xFFFEC000	0xFFFEC0FF
GIC	This address space is allocated for the Generic Interrupt Controller (GIC) registers.	0xFFFEC100	0xFFFEC1FF

Submodule Instance	Description	Start Address	End Address
Global Timer	This address space is allocated for the Global Timer registers.	0xFFFC200	0xFFFEC2FF
Reserved	This address space is reserved.	0xFFFEC300	0xFFFEC5FF
Private Timers and Watchdog Timers	This is the address space is allocated for private timer and watchdog timer registers.	0xFFFEC600	0xFFFEC6FF
Reserved	This address space is reserved. **Note:** Any access to this region causes a SLVERR abort exception.	0xFFFEC700	0xFFFEC7FF
Interrupt Distributor	This address space is allocated for the interrupt distributor registers.	0xFFFED000	0xFFFEDFFF
Reserved	This address space is reserved.	0xFFFEE000	0xFFFEEFFF

Related Information

Cortex-A9 MPCore Technical Reference Manual

For more information about the use of the MPU address space, refer to the *Cortex-A9 MPCore Technical Reference Manual*, available on the ARM Infocenter website.

L2 Cache Controller Address Map

The register space for the L2 cache controller ranges from 0xFFEF000 to 0xFFFEFFFF.

Table 9-16: MPU L2 Cache Controller Address Range

Module Instance	Start Address	End Address
MPUL2	0xFFFEF000	0xFFFEFFFF

Table 9-17: MPU L2 Cache Controller Register Range

Register Group	Description	Start Address	End Address
Cache ID and Cache Type	This address space is allocated for the cache ID and cache type registers.	0xFFFEF000	0xFFFEF0FF

Register Group	Description	Start Address	End Address
Control	This is the address space for the cache control registers.	0xFFFEF100	0xFFFEF1FF
Interrupt/Counter Control	This address space is allocated for the Interrupt/Counter control registers.	0xFFFEF200	0xFFFEF2FF
Reserved	This address space is reserved.	0xFFFEF300	0xFFFEF6FF
Cache Maintenance Operations	This is the address space is allocated for the cache maintenance operation registers.	0xFFFEF700	0xFFFEF7FF
Reserved	This address space is reserved.	0xFFFEF800	0xFFFEF8FF
Cache Lockdown	This address space is allocated for cache lockdown registers.	0xFFFEF900	0xFFFEF9FF
Reserved	This address space is reserved.	0xFFFEFA00	0xFFFEFBFF
Address Filtering	This address space is allocated for address filtering registers.	0xFFFEFC00	0xFFFEFCFF
Reserved	This address space is reserved.	0xFFFEFD00	0xFFFEFEFF
Debug, Prefetch, Power	This address space is allocated for debug, prefetch and power registers.	0xFFFEFF00	0xFFFEFFFF

Document Revision History

Date	Version	Changes
December 2014	2014.12.15	• Added bus transaction scenarios in the "Accelerator Coherency Port" section • Added the "AxUSER and AxCACHE Attributes" subsection to the "Accelerator Coherency Port" section • Added the "Shared Requests on ACP" subsection to the "Accelerator Coherency Port" section • Added the "Configuration for ACP Use" subsection to the "Accelerator Coherency Port" section • Clarified how to use fixed mapping mode in the ACP ID Mapper • Updated HPS Peripheral Master Input IDs table • Added a note to the "Control of the AXI User Sideband Signals" subsection in the "ACP ID Mapper" section. • Added parity error handling information to the "L1 Caches" section and the "Cache Controller Configuration" topic of the "L2 Cache" section.
June 2014	2014.06.30	• Added Reset Section to Cortex-A9 Processor • Updated HPS Peripheral Master Input IDs table • Added ACP ID Mapper Address Map and Register Definitions • Added information in ECC Support section regarding ECC errors • Minor clarifications regarding MPU description and module revision numbers
February 2014	2014.02.28	Maintenance release
December 2013	2013.12.30	Correct SDRAM region address in MPCore Address Map
November 2012	1.2	Minor updates.
May 2012	1.1	• Add description of the ACP ID mapper • Consolidate redundant information
January 2012	1.0	Initial release.

CoreSight Debug and Trace 10

2014.12.15

av_5v4 Subscribe Send Feedback

CoreSight systems provide all the infrastructure you require to debug, monitor, and optimize the performance of a complete HPS design. CoreSight technology addresses the requirement for a multicore debug and trace solution with high bandwidth for whole systems beyond the processor core.

CoreSight technology provides the following features:

- Cross-trigger support between SoC subsystems
- High data compression
- Multisource trace in a single stream
- Standard programming models for standard tool support

The hard processor system (HPS) debug infrastructure provides visibility and control of the HPS modules, the ARM Cortex-A9 microprocessor unit (MPU) subsystem, and user logic implemented in the FPGA fabric. The debug system design incorporates ARM CoreSight™ components.

Details of the ARM CoreSight debug components can be viewed by clicking on the related information links below.

Related Information

Features of CoreSight Debug and Trace

The CoreSight debug and trace system offers the following features:

- Real-time program flow instruction trace through a separate Program Trace Macrocell (PTM) for each processor
- Host debugger JTAG interface
- Connections for cross-trigger and STM-to-FPGA interfaces, which enable soft IP generation of triggers and system trace messages
- External trace interface through TPIU for trace analysis tools
- Custom message injection through STM into trace stream for delivery to host debugger
- STM and PTM trace sources multiplexed into a single stream through the Trace Funnel
- Capability to route trace data to any slave accessible to the ETR AXI master connected to the level 3 (L3) interconnect
- Capability for the following components to trigger each other through the embedded cross-trigger system:
  - FPGA fabric
  - Cortex-A9 CPU0 processor
  - Cortex-A9 CPU1 processor
  - Cortex-A9 Program Trace Macrocell (PTM)-0
  - Cortex-A9 PTM-1
  - System Trace Macrocell (STM)
  - Embedded Trace FIFO (ETF)
  - Embedded Trace Router (ETR)
  - Trace Port Interface Unit (TPIU)
  - csCross Trigger Interface (CTI)
  - CTI-0
  - CTI-1
  - FPGA-CTI
  - csCross Trigger Matrix (CTM)

Debug Access Port

The DAP provides the necessary ports for a host debugger to connect to and communicate with the HPS through a JTAG interface connected to dedicated HPS pins that is independent of the JTAG for the FPGA. The JTAG interface provided with the DAP allows a host debugger to access various modules inside the HPS. Additionally, a debug monitor executing on either processor can access different HPS components by interfacing with the system Advanced Microcontroller Bus Architecture (AMBA) Advanced Peripheral Bus (APB) slave port of the DAP. The system APB slave port occupies 2 MB of address space in the HPS. Both the JTAG port and system APB port have access to the debug APB master port of the DAP.

A host debugger can access any HPS memory-mapped resource in the system via the DAP system master port. Requests made over the DAP system master port are impacted by reads and writes to peripheral registers.

Note: The HPS JTAG interface does not support boundary scan tests (BST). To perform boundary scan testing on HPS I/Os, use the FPGA JTAG pins.

Related Information

- **CoreSight Debug and Trace Block Diagram and System Integration** on page 10-4
  For diagram information showing that all CoreSight components are connected to the debug APB.
- **ARM Infocenter**
  For more information, refer to the *CoreSight Components* Technical Reference Manual on the ARM info center website.

System Trace Macrocell

The STM allows messages to be injected into the trace stream for delivery to the host debugger receiving the trace data. These messages can be sent via stimulus ports or the hardware event interface. The STM allows the messages to be time stamped.

The STM provides an AMBA Advanced eXtensible Interface (AXI) slave interface used to create trace events. The interface can be accessed by the MPU subsystem, direct memory access (DMA) controller, and masters implemented as soft logic in the FPGA fabric via the FPGA-to-HPS bridge. The AXI slave interface supports three address segments, where each address segment is 16 MB and each segment supports up to 65536 channels. Each channel occupies 256 bytes of address space.

The STM also provides 32 hardware event pins. The higher-order 28 pins (31:4) are connected to the FPGA fabric, allowing logic inside FPGA to insert messages into the trace stream. When the STM detects a rising edge on an event pin, a message identifying the event is inserted into the stream. The lower four event pins (3:0) are connected to csCTI.

Related Information

- **HPS-FPGA Bridges** on page 8-1
- **ARM Infocenter**
  For more information, refer to the *CoreSight System Trace Macrocell* Technical Reference Manual on the ARM info center website.
- **csCTI** on page 10-20

Trace Funnel

The Trace Funnel multiplexes three trace sources into a single trace stream. Port 0 of the Trace Funnel is connected to the PTM for CPU 0. Port 1 of the Trace Funnel is connected to the PTM for CPU 1. Port 3 of the Trace Funnel is connected to the STM. Port 2 and Port 4 through Port 7 are not used.

Related Information

- **ARM Infocenter**
  For more information, refer to the *CoreSight Components* Technical Reference Manual on the ARM info center website.
- **Program Trace Macrocell** on page 10-12

Embedded Trace FIFO

The output of the Trace Funnel is sent to the ETF. The ETF is used as an elastic buffer between trace generators (STM, PTM) and trace destinations. The ETF stores up to 32 KB of trace data in the on-chip trace RAM.

AMBA Trace Bus Replicator

The AMBA Trace Bus Replicator broadcasts trace data from the ETF to the ETR and TPIU.

Related Information

ARM Infocenter
For more information, refer to the *CoreSight Components* Technical Reference Manual on the ARM info center website.

Embedded Trace Router

The ETR can route trace data to the HPS on-chip RAM, the HPS SDRAM, and any memory in the FPGA fabric connected to the HPS-to-FPGA bridge. The ETR receives trace data from the AMBA Trace Bus Replicator. By default, the buffer to receive the trace data resides in SDRAM at offset 0x00100000 and is 32 KB. You can override this default configuration by programming registers in the ETR.

Related Information

- **HPS-FPGA Bridges** on page 8-1
- **CoreSight Debug and Trace Programming Model** on page 10-17

Trace Port Interface Unit

The TPIU is a bridge between on-chip trace sources and an off-chip trace port. The TPIU receives trace data from the Replicator and drives the trace data to a trace port analyzer.

The trace output from the TPIU is software programmable and can be set to either 8 or 32 bits wide. The trace output is routed to an 8-bit HPS I/O interface and a 32-bit interface to the FPGA fabric. The trace data sent to the FPGA fabric can be transported off-chip using available serializer/deserializer (SERDES) resources in the FPGA.

Related Information

ARM Infocenter

For more information, refer to the *CoreSight Components* Technical Reference Manual on the ARM info center website.

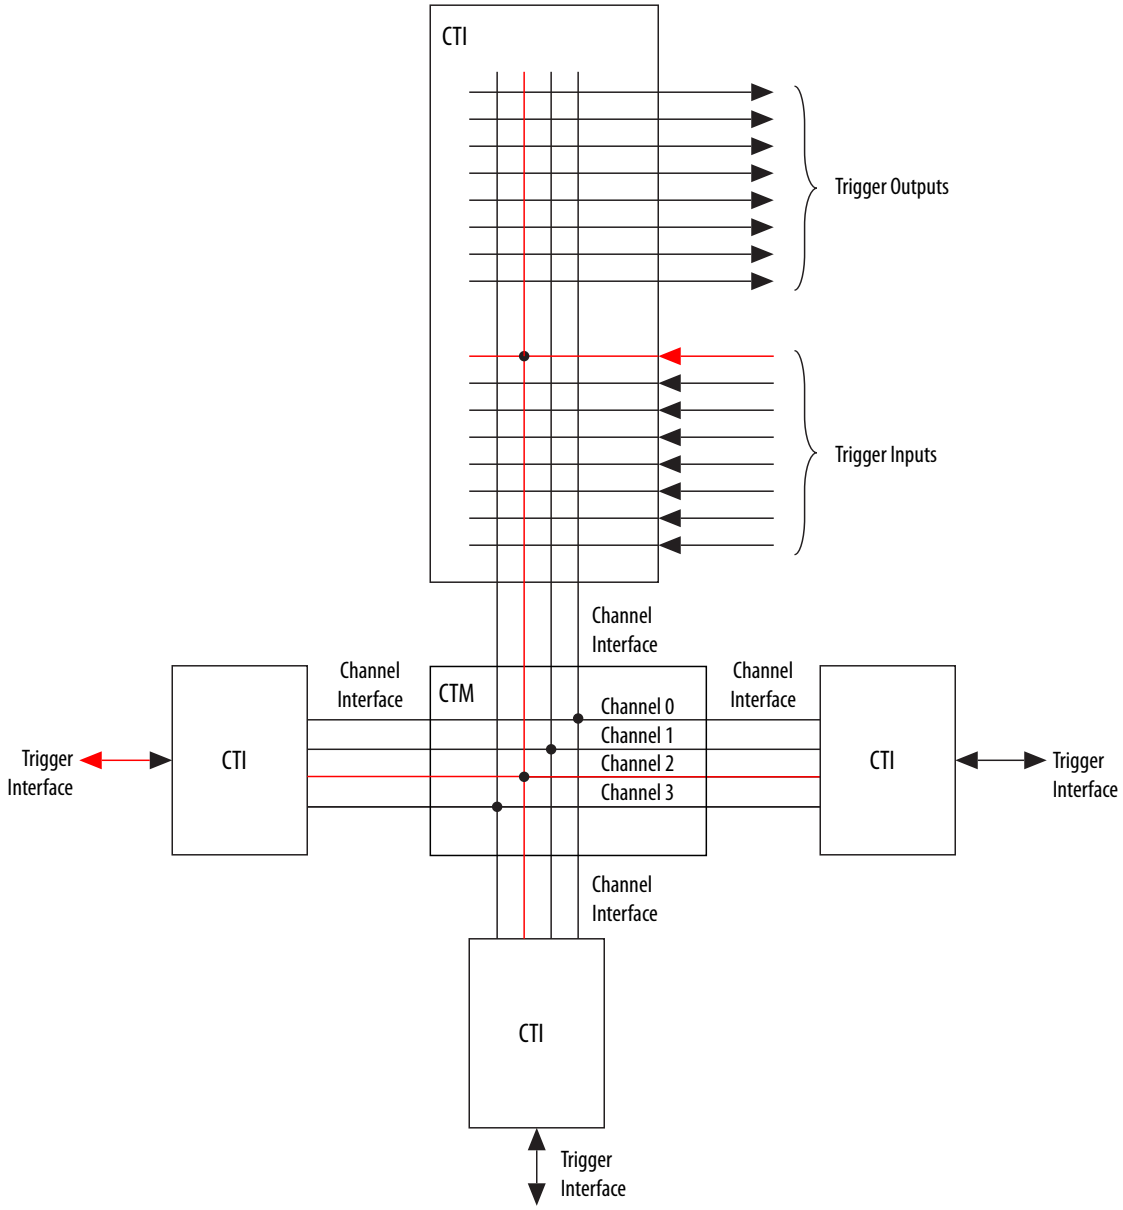
Embedded Cross Trigger System

The ECT system provides a mechanism for the components listed in the "Features of the Coresight Debug and Trace" chapter to trigger each other. The ECT consists of the following modules:

- Cross Trigger Interface (CTI)
- Cross Trigger Matrix (CTM)

Figure 10-2: Generic ECT System

The following figure shows an example of how CTIs and CTMs are used in a generic ECT setup. The red line depicts an trigger input to one CTI generating a trigger output in another CTI. Though the signal travels through channel 2, it only enters and exits through trigger inputs and outputs you configure.



Related Information

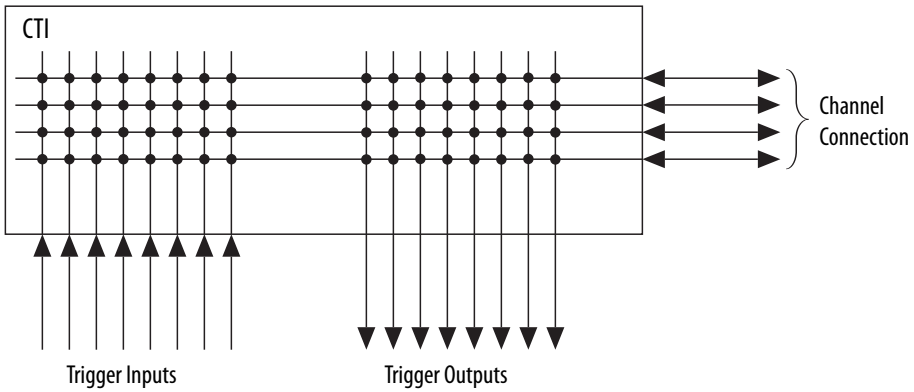
- **Cross Trigger Interface** on page 10-9
- **Features of CoreSight Debug and Trace** on page 10-2
- **Cross Trigger Matrix** on page 10-9

Cross Trigger Interface

CTIs allow trigger sources and sinks to interface with the ECT. Each CTI supports up to eight trigger inputs and eight trigger outputs, and is connected to a CTM. Figure 10-2 shows the relationship of trigger inputs, trigger outputs, and CTM channels of a CTI.

Figure 10-3: CTI Connections

The following figure shows the eight potential trigger input and trigger output connections that are supported.



The HPS debug system contains the following CTIs:

- csCTI—performs cross triggering between the STM, ETF, ETR, and TPIU.
- FPGA-CTI—exposes the cross-triggering system to the FPGA fabric.
- CTI-0 and CTI-1—reside in the MPU debug subsystem. Each CTI is associated with a processor and the processor's associated PTM.

Cross Trigger Matrix

A CTM is a transport mechanism for triggers traveling from one CTI to one or more CTIs or CTMs. The HPS contains two CTMs. One CTM connectscsCTI and FPGA-CTI; the other connects CTI-0 and CTI-1. The two CTMs are connected together, allowing triggers to be transmitted between the MPU debug subsystem, the debug system, and the FPGA fabric.

Each CTM has four ports and each port has four channels. Each CTM port can be connected to a CTI or another CTM.

Figure 10-4: CTM Channel Structure

The following figure shows the structure of a CTM channel. Paths inside the CTM are purely combinatorial.

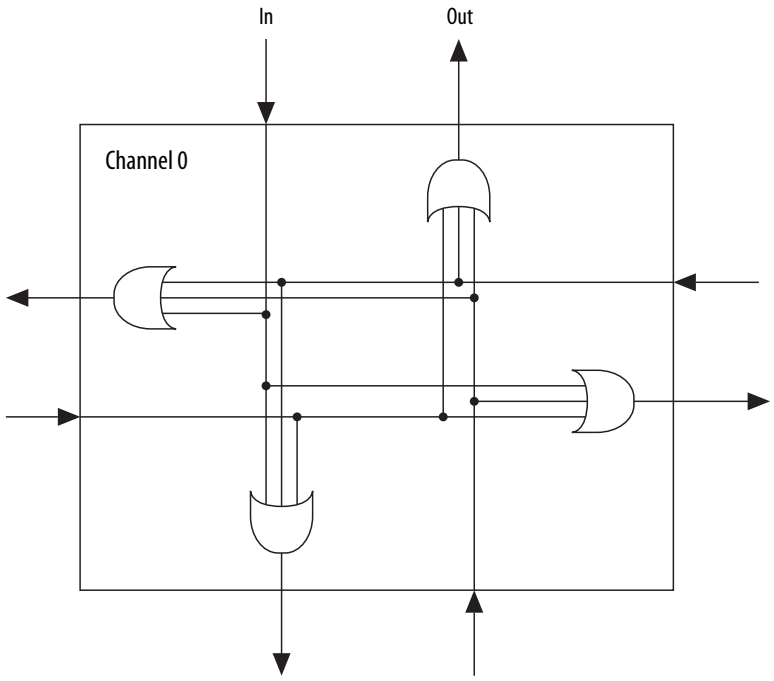


Figure 10-5: CTI Trigger Connections

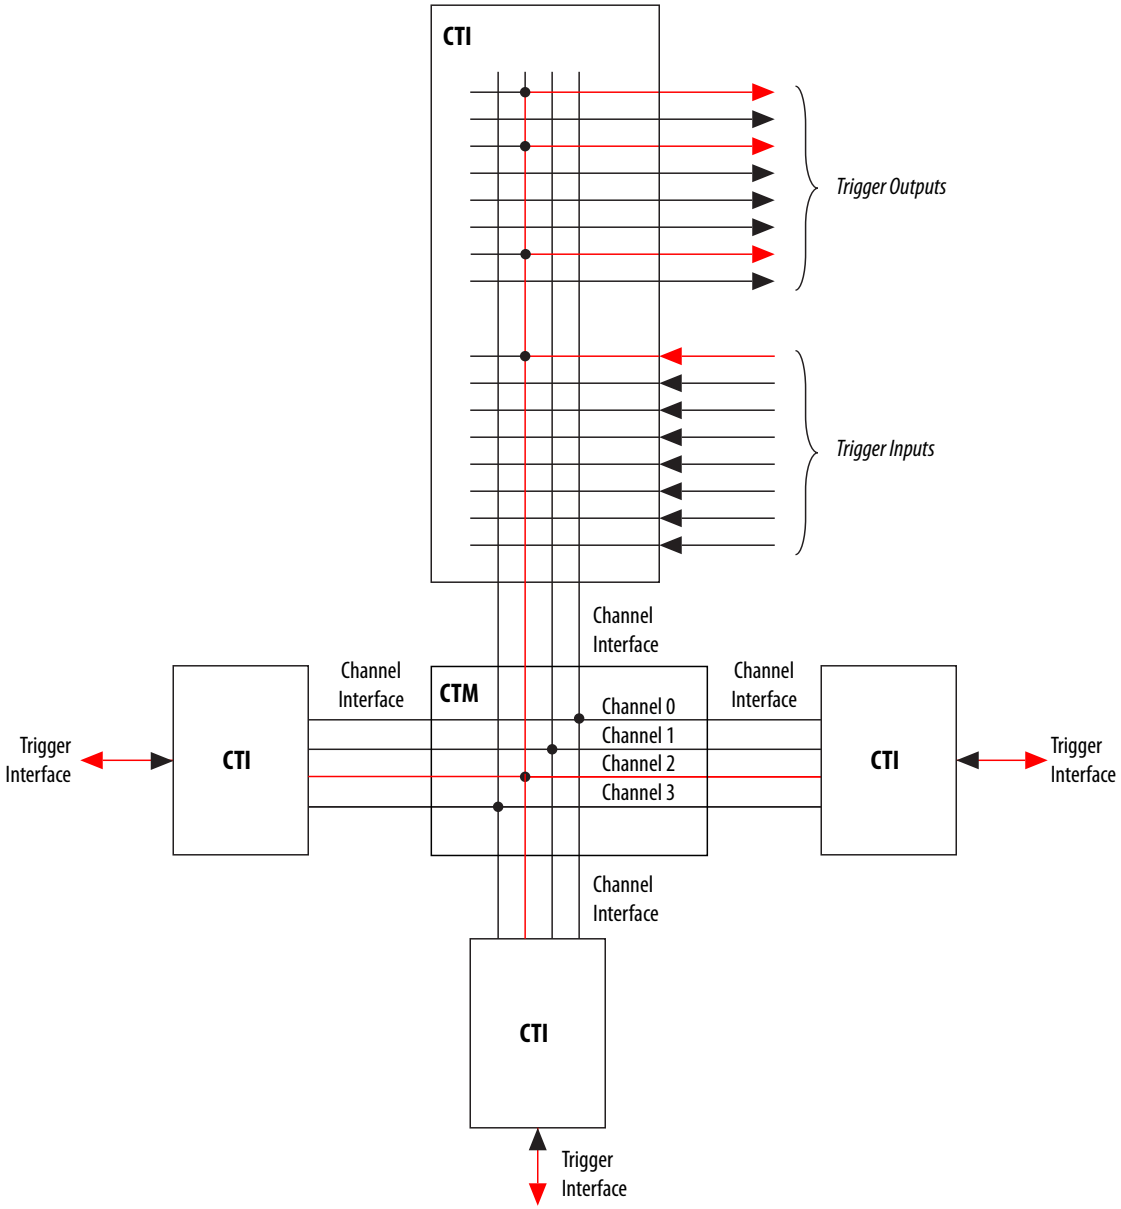
Each CTI trigger input can be connected through a CTM to one or more trigger outputs under control by a debugger. The following figure shows an example of CTI trigger connections. The red lines depict the impact one trigger input can have on the entire system.



Related Information

ARM Infocenter

For more information, refer to the *CoreSight Components* Technical Reference Manual on the ARM info center website.

Program Trace Macrocell

The PTM performs real-time program flow instruction tracing and provides a variety of filters and triggers that can be used to trace specific portions of code.

The HPS contains two PTMs. Each PTM is paired with a processor and CTI. Trace data generated from the PTM can be transmitted off-chip using HPS pins, or to the FPGA fabric, where it can be pre-processed and transmitted off-chip using high-speed FPGA pins.

Related Information

ARM Infocenter
For more information, refer to the *CoreSight PTM-A9* Technical Reference Manual.

HPS Debug APB Interface

The HPS can extend the CoreSight debug control bus into the FPGA fabric. The debug interface is an APB-compatible interface with built-in clock crossing.

Related Information

- **FPGA Interface** on page 10-12
- **HPS Component Interfaces** on page 27-1

FPGA Interface

The following components connect to the FPGA fabric. This section lists the signals from the debug system to the FPGA.

DAP

The DAP uses the system APB port to connect to the FPGA.

Table 10-1: DAP

The following table shows the signal description between DAP and FPGA.

Signal	Description
h2f_dbg_apb_PADDR	Address bus to system APB port, when PADDR
h2f_dbg_apb_PADDR31	Address bus to system APB port, when PADDR31
h2f_dbg_apb_PENABLE	Enable signal from system APB port
h2f_dbg_apb_PRDATA[32]	32-bit system APB port read data bus
h2f_dbg_apb_PREADY	Ready signal to system APB port
h2f_dbg_apb_PSEL	Select signal from system APB port
h2f_dbg_apb_PSLVERR	Error signal to system APB port
h2f_dbg_apb_PWDATA[32]	32-bit system APB port write data bus

Signal	Description
h2f_dbg_apb_PWRITE	Select whether read or write to system APB port • 0 - System APB port read from DAP • 1 - System APB Port write to DAP

STM

The STM has 28 event pins, f2h_stm_hw_events[28], for FPGA to trigger events to STM.

FPGA-CTI

The FPGA-CTI allows the FPGA to send and receive triggers from the debug system.

Table 10-2: FPGA-CTI

The following table lists the signal descriptions between the FPGA-CTI and FPGA.

Signal	Description
h2f_cti_trig_in[8]	Trigger input from FPGA
h2f_cti_trig_in_ack[8]	ACK signal to FPGA
h2f_cti_trig_out[8]	Trigger output to FGPA
h2f_cti_trig_out_ack[8]	ACK signal from FPGA
h2f_cti_clk	Clock input from FPGA
h2f_cti_fpga_clk_en	Clock enable driven by FPGA
h2f_cti_asicctl[8]	Signal from FPGA

Related Information

ARM Infocenter

TPIU

Figure 10-6: Trace Clock and Trace Data Width

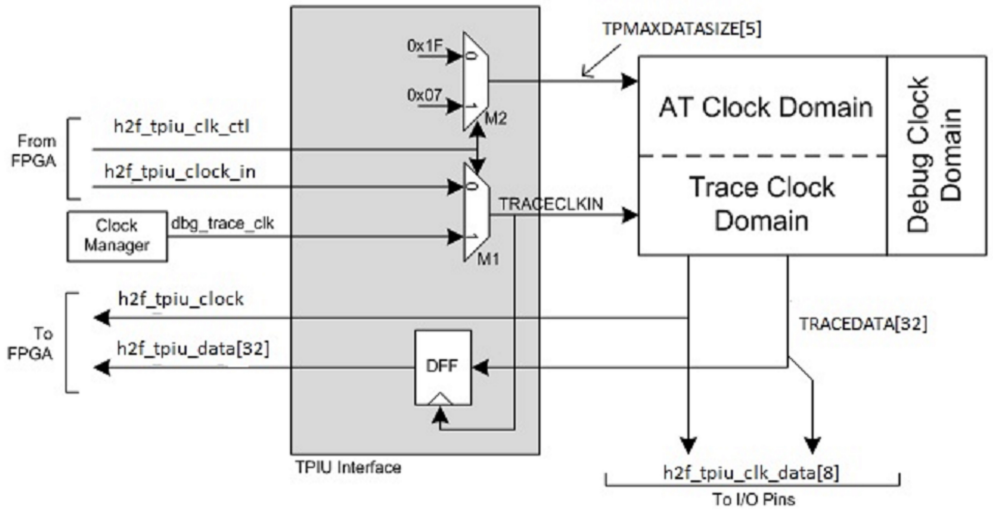


Table 10-3: TPIU Signals

The following table lists the signal descriptions between the TPIU and FPGA.

Signal	Description
h2f_tpiu_clk_ctl	Selects whether trace data is captured using the internal TPIU clock, which is the `dbg_trace_clk` signal from the clock manager; or an external clock provided as an input to the TPIU from the FPGA. 0 - use h2f_tpiu_clock_in 1 - use internal clock Note: When the FPGA is powered down or not configured the TPIU uses the internal clock.
h2f_tpiu_data[32]	32 bit trace data bus to the FPGA. Trace data changes on both edges of h2f_tpiu_clock. Note: When the FPGA is powered down or not configured, the TPIU sends the lower 8-bits trace data to I/Os.
h2f_tpiu_clock_in	Clock from the FPGA used to capture trace data.

Signal	Description
h2f_tpiu_clock	Clock output from TPIU

Debug Clocks

The CoreSight system uses several different clocks.

Table 10-4: CoreSight Clocks

ARM Clock Name	Clock Source	HPS Clock Signal Name	Description
ATCLK	Clock manager	dbg_at_clk	Trace bus clock.
CTICLK (for csCTI)	Clock manager	dbg_at_clk	Cross trigger interface clock for csCTI. It can be synchronous or asynchronous to CTMCLK.
CTICLK (for FPGA-CTI)	FPGA fabric	fpga_cti_clk	Cross trigger interface clock for FPGA-CTI.
CTICLK (for CTI-0 and CTI-1)	Clock manager	mpu_clk	Cross trigger interface clock for CTI-0 and CTI-1. It can be synchronous or asynchronous to CTMCLK.
CTMCLK (for csCTM)	Clock manager	dbg_clk	Cross trigger matrix clock for csCTM. It can be synchronous or asynchronous to CTICLK.
CTMCLK (for CTM)	Clock manager	mpu_clk	Cross trigger matrix clock for CTM. It can be synchronous or asynchronous to CTICLK.
DAPCLK	Clock manager	dbg_clk	DAP internal clock. It must be equivalent to PCLKDBG.
PCLKDBG	Clock manager	dbg_clk	Debug APB (DAPB) clock.
HCLK	Clock manager	dbg_clk	Used by the AHB-Lite master inside the DAP. It is asynchronous to DAPCLK. In the HPS, the AHB-Lite port uses same clock as DAPCLK.
PCLKSYS	Clock manager	l4_mp_clk	Used by the APB slave port inside the DAP. It is asynchronous to DAPCLK.

ARM Clock Name	Clock Source	HPS Clock Signal Name	Description
SWCLKTCK	JTAG interface FPGA fabric **Note:** There are two clock soures.	dap_tck tpiu_traceclkin **Note:** There are two signal names.	The SWJ-DP clock driven by the external debugger through either the JTAG interface or the FPGA fabric. It is asynchronous to DAPCLK. When through the JTAG interface, this clock is the same as TCK of the JTAG interface.
TRACECLKIN	Clock manager	dbg_trace_clk	TPIU trace clock input. It is asynchronous to ATCLK. In the HPS, this clock can come from the clock manager or the FPGA fabric.

Related Information

ARM Infocenter

For more information about the CoreSight port names, refer to the *CoreSight Technology System* Design Guide, which you can download from the ARM info center website.

Debug Resets

The CoreSight system uses several resets.

Table 10-5: CoreSight Resets

ARM Reset Name	Clock Source	HPS Reset Signal Name	Description
ATRESETn	Reset manager	dbg_rst_n	Trace bus reset. It resets all registers in ATCLK domain.
nCTIRESET	Reset manager	dbg_rst_n	CTI reset signal. It resets all registers in CTICLK domain. In the HPS, there are four instances of CTI. All four use the same reset signal.
DAPRESETn	Reset manager	dbg_rst_n	DAP internal reset. It is connected to PRESETDBGn.
PRESETDBGn	Reset manager	dbg_rst_n	Debug APB reset. Resets all registers clocked by PCLKDBG.
HRESETn	Reset manager	sys_dbg_rst_n	SoC-provided reset signal that resets all of the AMBA on-chip interconnect. Use this signal to reset the DAP AHB-Lite master port.

ARM Reset Name	Clock Source	HPS Reset Signal Name	Description
PRESETSYSn	Reset manager	sys_dbg_rst_n	Resets system APB slave port of DAP.
nCTMRESET	Reset manager	dbg_rst_n	CTM reset signal. It resets all signals clocked by CTMCLK.
nPOTRST	Reset manager	tap_cold_rst_n	True power on reset signal to the DAP SWJ-DP. It must only reset at power-on.
nTRST	JTAG interface	nTRST pin	Resets the DAP TAP controller inside the SWJ-DP. This signal is driven by the host using the JTAG connector.
TRESETn	Reset manager	dbg_rst_n	Reset signal for TPIU. Resets all registers in the TRACECLKIN domain.

The ETR stall enable field (etrstallen) of the ctrl register in the reset manager controls whether the ETR is requested to stall its AXI master interface to the L3 interconnect before a warm or debug reset.

The level 4 (L4) watchdog timers can be paused during debugging to prevent reset while the processor is stopped at a breakpoint.

  For more information about the CoreSight port names, refer to the *CoreSight Technology System* Design Guide.

CoreSight Debug and Trace Programming Model

This section describes programming model details specific to Altera's implementation of the ARM CoreSight technology.

The debug components can be configured to cause triggers when certain events occur. For example, soft logic in the FPGA fabric can signal an event which triggers an STM message injection into the trace stream.

Related Information

ARM Infocenter
Programming interface details of each CoreSight component.

Coresight Component Address

CoreSight components are configured through memory-mapped registers, located at offsets relative to the CoreSight component base address. CoreSight component base addresses are accessible through the component address table in the DAP ROM.

Table 10-6: Coresight Component Address Table

The following table is located in the ROM table portion of the DAP.

ROM Entry	Offset[30:12]	Description
0x0	0x00001	ETF Component Base Address
0x1	0x00002	CTI Component Base Address
0x2	0x00003	TPIU Component Base Address
0x3	0x00004	Trace Funnel Component Base Address
0x4	0x00005	STM Component Base Address
0x5	0x00006	ETR Component Base Address
0x6	0x00007	FPGA-CTI Component Base Address
0x7	0x00100	A9 ROM
0x8	0x00080	FPGA ROM
0x9	0x00000	End of rOM

A host debugger can access this table at 0x80000000 through the DAP. HPS masters can access this ROM at 0xFF000000. Registers for a particular CoreSight component are accessed by adding the register offset to the CoreSight component base address, and adding that total to the base address of the ROM table.

The base address of the ROM table is different when accessed from the debugger (at 0x8000_0000) than when accessed from any HPS master (at 0xFF000000). For example, the CTI output enable (CTIOUTEN) register, `CTIOUTEN[2]` at offset 0xA8, can be accessed by the host debugger at 0x800020A8. To derive that value, add the host debugger access address to the ROM table of 0x80000000, to the CTI component base address of 0x00002000, to the `CTIOUTEN[2]` register offset of 0xA8.

STM Channels

The STM AXI slave is connected to the MPU, DMA, and FPGA-to-HPS bridge masters. Each master has up to 65536 channels where each channel occupies 256 bytes of address space, for a total of 16 MB per master. The HPS address map allocates 48 MB of consecutive address space to the STM AXI slave port, divided in three 16 MB segments.

Table 10-7: STM AXI Slave Port Address Allocation

Segment	Start Address	End Address
0	0xFC000000	0xFCFFFFFF
1	0xFD000000	0xFDFFFFFF
2	0xFE000000	0xFEFFFFFF

Each of the three masters can access any one of the three address segments. Your software design determines which master uses which segment, based on the value of bits 24 and 25 in the write address, `AWADDRS[25:24]`. Software must restrict each master to use only one of the three segments.

Table 10-8: STM AXI Address Fields

STM receives trace data over an AXI slave port. This table contains a list of signals associated with this interface.

AXI Signal Fields	Description
`AWADDRS[7:0]`	These bits index the 256 bytes of the stimulus port.
`AWADDRS[23:8]`	These bits identify the 65536 stimulus ports associated with a master.
`AWADDRS[25:24]`	These bits identify the three masters. Only 0, 1, and 2 are valid values.
`AWADDRS[31:26]`	Always 0x3F. Bits 24 to 31 combine to access 0xFC000000 through 0xFEFFFFFF.

Each STM message contains a master ID that tells the host debugger which master is associated with the message. The STM master ID is determined by combining a portion of the `AWADDRS` signal and the `AWPROT` protection bit. In the following table, `MasterID[6]` identifies the

Table 10-9: STM Master ID Calculation

Master ID Bits	AXI Signal Bits	Notes
Master ID[5:0]	`AWADDRS[29:24]`	The lowest two bits are sufficient to determine which master, but CoreSight uses a six-bit master ID.
Master ID[6]	`AWPROT[1]`	0 indicates a secure master; 1 indicates a nonsecure master.

In addition to access through STM channels, the higher-order 28 (31:4) of the 32 event signals are attached to the FPGA through the FPGA-CTI. These event signals allow the FPGA fabric to send additional messages using the STM.

FPGA-CTI

FPGA-CTI connects the debug system to the FPGA fabric. FPGA-CTI has all of its triggers available to the FPGA fabric.

Related Information

Configuring Embedded Cross-Trigger Connections on page 10-21
For more information about the triggers, refer to the "Configuring Embedded Cross-Trigger Connections" chapter.

Configuring Embedded Cross-Trigger Connections

CTI interfaces are programmable through a memory-mapped register interface.

The specific registers are described in the *CoreSight Components Technical Reference Manual*, which you can download from the ARM Infocenter.

To access registers in any CoreSight component through the debugger, the register offsets must be added to the CoreSight component's base address. That combined value must then be added to the address at which the ROM table is visible to the debugger (0x80000000).

Each CTI has two interfaces, the trigger interface and the channel interface. The trigger interface is the interface between the CTI and other components. It has eight trigger signals, which are hardwired to other components. The channel interface is the interface between a CTI and its CTM, with four bidirectional channels. The mapping of trigger interface to channel interface (and vice versa) in a CTI is dynamically configured. You can enable or disable each CTI trigger output and CTI trigger input connection individually.

For example, you can configure trigger input 0 in the FPGA-CTI to route to channel 3, and configure trigger output 3 in the FPGA-CTI and trigger output 7 in CTI-0 in the MPU debug subsystem to route from channel 3. This configuration causes a trigger at trigger input 0 in FPGA-CTI to propagate to trigger output 3 in the FPGA-CTI and trigger output 7 in CTI-0. Propagation can be single-to-single, single-to-multiple, multiple-to-single, and multiple-to-multiple.

A particular soft logic signal in the FPGA connected to a trigger input in the FPGA-CTI can be configured to trigger a flush of trace data to the TPIU. For example, you can configure channel 0 to trigger output 2 in csCTI. Then configure trigger input T3 to channel 0 in FPGA-CTI. Trace data is flushed to the TPIU when a trigger is received at trigger output 2 in csCTI.

Another soft logic signal in the FPGA connected to trigger input T2 in FPGA-CTI can be configured to trigger an STM message. csCTI output triggers 4 and 5 are wired to the STM CoreSight component in the HPS. For example, configure channel 1 to trigger output 4 in csCTI. Then configure trigger input T2 to channel 1 in FPGA-CTI.

Another soft logic signal in the FPGA fabric connected to trigger input T1 in FPGA-CTI can be configured to trigger a breakpoint on CPU 1. Trigger output 1 in CTI-1 is wired to the debug request (EDBGRQ) signal of CPU-1. For example, configure channel 2 to trigger output 1 in CTI-1. Then configure trigger input T1 to channel 2 in FPGA-CTI.

Related Information

- **ARM Infocenter**
- **ARM Infocenter**

Configuring Trigger Input 0

For example, you can configure trigger input 0 in the FPGA-CTI to route to channel 3, and configure trigger output 3 in the FPGA-CTI and trigger output 7 in CTI-0 in the MPU debug subsystem to route from channel 3. This configuration causes a trigger at trigger input 0 in FPGA-CTI to propagate to trigger output 3 in the FPGA-CTI and trigger output 7 in CTI-0. Propagation can be single-to-single, single-tomultiple, multiple-to-single, or multiple-to-multiple.

Triggering a Flush of Trace Data to the TPIU

A particular soft logic signal in the FPGA connected to a trigger input in the FPGA-CTI can be configured to trigger a flush of trace data to the TPIU. For example, you can configure channel 0 to trigger output 2 in csCTI. Then configure trigger input T3 to channel 0 in FPGA-CTI. Trace data is flushed to the TPIU when a trigger is received at trigger output 2 in csCTI.

Triggering an STM message

Another soft logic signal in the FPGA connected to trigger input T2 in FPGA-CTI can be configured to trigger an STM message. csCTI output triggers 4 and 5 are wired to the STM CoreSight component in the HPS. For example, configure channel 1 to trigger output 4 in csCTI. Then configure trigger input T2 to channel 1 in FPGA-CTI.

Triggering a Breakpoint on CPU 1

Another soft logic signal in the FPGA fabric connected to trigger input T1 in FPGA-CTI can be configured to trigger a breakpoint on CPU 1. Trigger output 1 in CTI-1 is wired to the external debug request (EDBGRQ) signal of CPU-1. For example, configure channel 2 to trigger output 1 in CTI-1. Then configure trigger input T1 to channel 2 in FPGA-CTI.

CoreSight Debug and Trace Address Map and Register Definitions

The address map and register definitions for CoreSight Debug and Trace consist of the following regions:

System Trace Macrocell (STM) Module Address Map on page 10-23

SDRAM Controller Subsystem 11

2014.12.15

av_5v4 Subscribe Send Feedback

The hard processor system (HPS) SDRAM controller subsystem provides efficient access to external SDRAM for the ARM Cortex-A9 microprocessor unit (MPU) subsystem, the level 3 (L3) interconnect, and the FPGA fabric. The SDRAM controller provides an interface between the FPGA fabric and HPS. The interface accepts Advanced Microcontroller Bus Architecture (AMBA) Advanced eXtensible Interface (AXI) and Avalon® Memory-Mapped (Avalon-MM) transactions, converts those commands to the correct commands for the SDRAM, and manages the details of the SDRAM access.

Features of the SDRAM Controller Subsystem

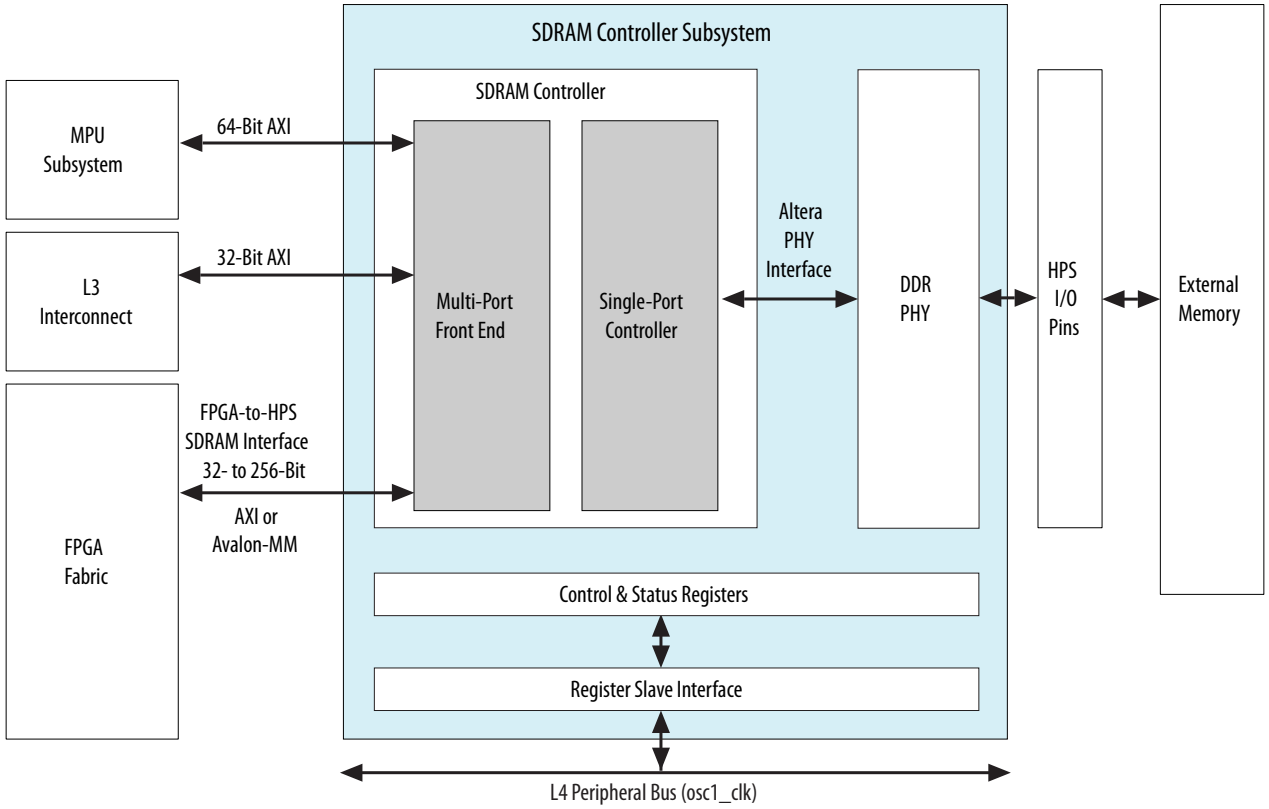
The SDRAM controller subsystem offers programming flexibility, port and bus configurability, error correction, and power management for external memories up to 4 GB.

- Support for double data rate 2 (DDR2), DDR3, and low-power DDR2 (LPDDR2) SDRAM
- Flexible row and column addressing with the ability to support up to 4 GB of memory in various interface configurations
- Optional 8-bit integrated error correction code (ECC) for 16- and 32-bit data widths
- User-configurable memory width of 8, 16, 16+ECC, 32, 32+ECC
- User-configurable timing parameters
- Two chip selects (DDR2 and DDR3)
- Command reordering (look-ahead bank management)
- Data reordering (out of order transactions)
- User-controllable bank policy on a per port basis for either closed page or conditional open page accesses
- User-configurable priority support with both absolute and weighted round-robin scheduling
- Flexible FPGA fabric interface with up to 6 ports that can be combined for a data width up to 256 bits wide using Avalon-MM and AXI interfaces.
- Power management supporting self refresh, partial array self refresh (PASR), power down, and LPDDR2 deep power down

SDRAM Controller Subsystem Block Diagram

The SDRAM controller subsystem connects to the MPU subsystem, the main switch of the L3 interconnect, and the FPGA fabric. The memory interface consists of the SDRAM controller, the physical layer (PHY), control and status registers (CSRs), and their associated interfaces.

Figure 11-1: SDRAM Controller Subsystem High-Level Block Diagram



SDRAM Controller

The SDRAM controller provides high performance data access and run-time programmability. The controller reorders data to reduce row conflicts and bus turn-around time by grouping read and write transactions together, allowing for efficient traffic patterns and reduced latency.

The SDRAM controller consists of a multiport front end (MPFE) and a single-port controller. The MPFE provides multiple independent interfaces to the single-port controller. The single-port controller communicates with and manages each external memory device.

The MPFE FPGA-to-HPS SDRAM interface port has an asynchronous FIFO buffer followed by a synchronous FIFO buffer. Both the asynchronous and synchronous FIFO buffers have a read and write data FIFO depth of 8, and a command FIFO depth of 4. The MPU sub-system 64-bit AXI and L3 interconnect 32-bit AXI have asynchronous FIFO buffers with read and write data FIFO depth of 8, and command FIFO depth of 4.

DDR PHY

The DDR PHY provides a physical layer interface for read and write memory operations between the memory controller and memory devices. The DDR PHY has dataflow components, control components, and calibration logic that handle the calibration for the SDRAM interface timing.

	2048 (2 Gb) - S2 (21)	11	2	15	256	2048
	2048 (2 Gb) -S4 (22)	11	3	14	256	2048
	4096 (4 Gb)	12	3	14	512	4096

SDRAM Controller Subsystem Interfaces

MPU Subsystem Interface

The SDRAM controller connects to the MPU subsystem with a dedicated 64-bit AXI interface, operating on the `mpu_l2_ram_clk` clock domain.

L3 Interconnect Interface

The SDRAM controller interfaces to the L3 interconnect with a dedicated 32-bit AXI interface, operating on the `l3_main_clk` clock domain.

Related Information

System Interconnect on page 7-1

(20) For all memory types shown in this table, the DQ width is 8.
(21) S2 signifies a 2n prefetch size
(22) S4 signifies a 4n prefetch size

CSR Interface

The CSR interface connects to the level 4 (L4) bus and operates on the `l4_sp_clk` clock domain. The MPU subsystem uses the CSR interface to configure the controller and PHY, for example, setting the memory timing parameter values or placing the memory to a low power state. The CSR interface also provides access to the status registers in the controller and PHY.

FPGA-to-HPS SDRAM Interface

The FPGA-to-HPS SDRAM interface provides masters implemented in the FPGA fabric access to the SDRAM controller subsystem in the HPS. The interface has three ports types that are used to construct the following AXI or Avalon-MM interfaces:

- Command ports—issue read and/or write commands, and for receive write acknowledge responses
- 64-bit read data ports—receive data returned from a memory read
- 64-bit write data ports—transmit write data

The FPGA-to-HPS SDRAM interface supports six command ports, allowing up to six Avalon-MM interfaces or three AXI interfaces. Each command port can be used to implement either a read or write command port for AXI, or be used as part of an Avalon-MM interface. The AXI and Avalon-MM interfaces can be configured to support 32-, 64-, 128-, and 256-bit data.

Table 11-2: FPGA-to-HPS SDRAM Controller Port Types

Port Type	Available Number of Ports
Command	6
64-bit read data	4
64-bit write data	4

The FPGA-to-HPS SDRAM controller interface can be configured with the following characteristics:

- Avalon-MM interfaces and AXI interfaces can be mixed and matched as required by the fabric logic, within the bounds of the number of ports provided to the fabric.
- Because the AXI protocol allows simultaneous read and write commands to be issued, two SDRAM control ports are required to form an AXI interface.
- Because the data ports are natively 64-bit, they must be combined if wider data paths are required for the interface.
- Each Avalon-MM or AXI interface of the FPGA-to-HPS SDRAM interface operates on an independent clock domain.
- The FPGA-to-HPS SDRAM interfaces are configured during FPGA configuration.

The following table shows the number of ports needed to configure different bus protocols, based on type and data width.

Table 11-3: FPGA-to-HPS SDRAM Port Utilization

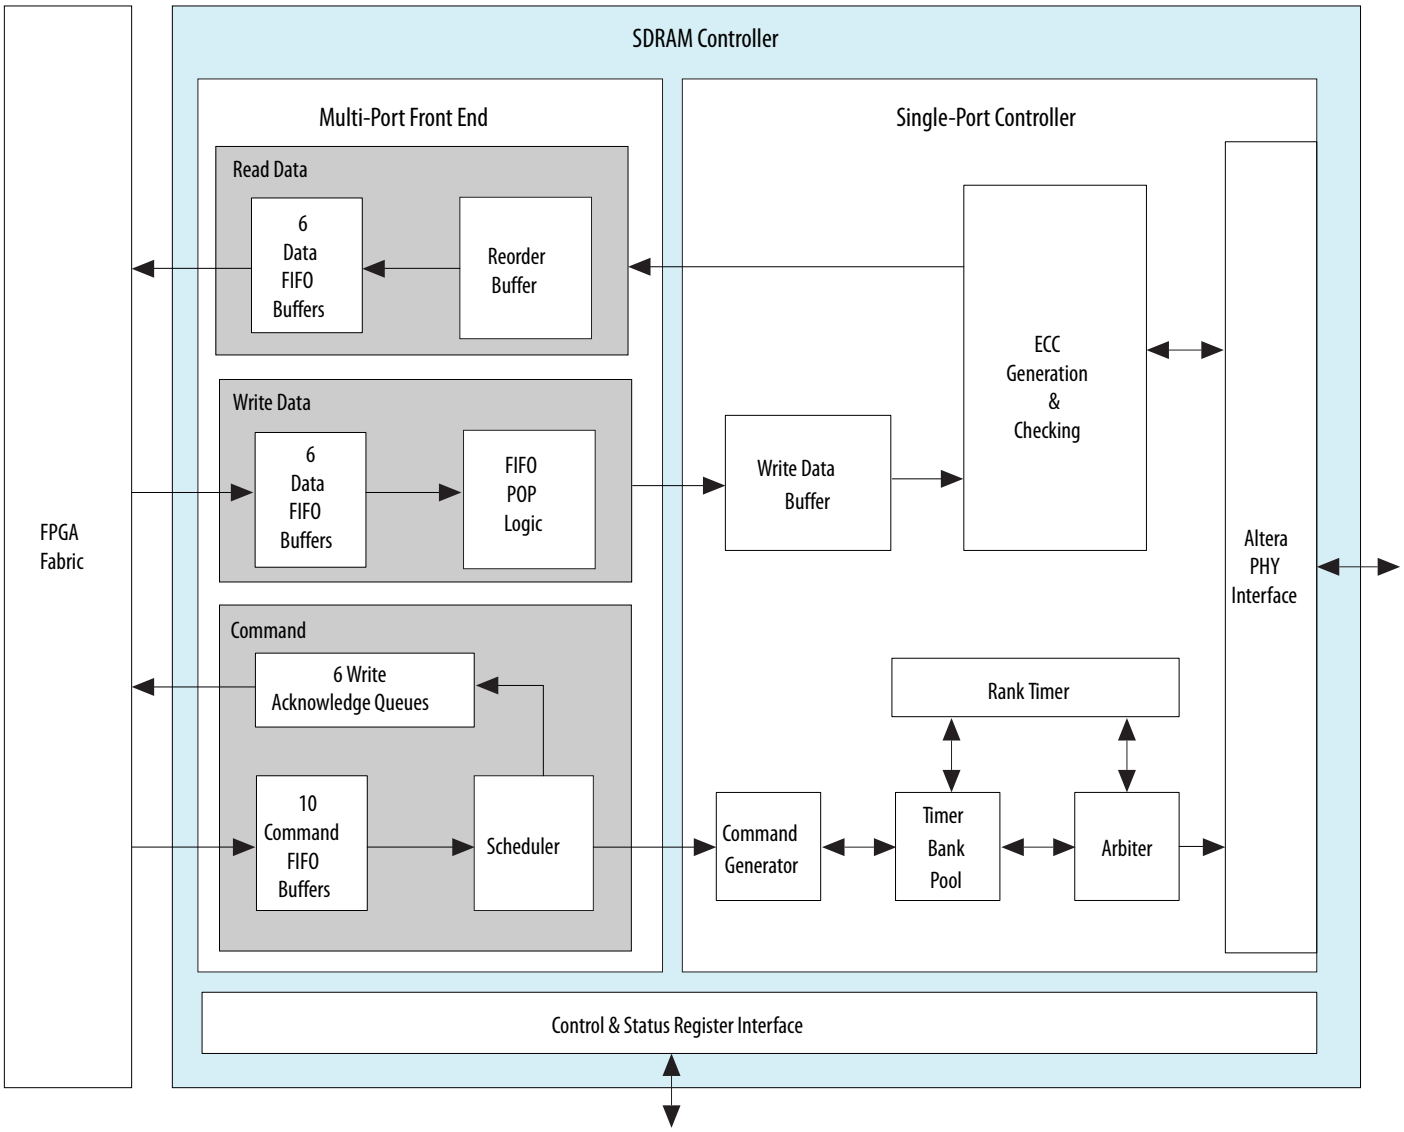
Bus Protocol	Command Ports	Read Data Ports	Write Data Ports
32- or 64-bit AXI	2	1	1

Bus Protocol	Command Ports	Read Data Ports	Write Data Ports
128-bit AXI	2	2	2
256-bit AXI	2	4	4
32- or 64-bit Avalon-MM	1	1	1
128-bit Avalon-MM	1	2	2
256-bit Avalon-MM	1	4	4
32- or 64-bit Avalon-MM write-only	1	0	1
128-bit Avalon-MM write-only	1	0	2
256-bit Avalon-MM write-only	1	0	4
32- or 64-bit Avalon-MM read-only	1	1	0
128-bit Avalon-MM read-only	1	2	0
256-bit Avalon-MM read-only	1	4	0

Memory Controller Architecture

The SDRAM controller consists of an MPFE, a single-port controller, and an interface to the CSRs.

Figure 11-2: SDRAM Controller Block Diagram



Multi-Port Front End

The Multi-Port Front End (MPFE) is responsible for scheduling pending transactions from the configured interfaces and sending the scheduled memory transactions to the single-port controller. The MPFE handles all functions related to individual ports.

The MPFE consists of three primary sub-blocks.

Command Block

The command block accepts read and write transactions from the FPGA fabric and the HPS. When the command FIFO buffer is full, the command block applies backpressure by deasserting the ready signal. For each pending transaction, the command block calculates the next SDRAM burst needed to progress on that transaction. The command block schedules pending SDRAM burst commands based on the user-supplied configuration, available write data, and unallocated read data space.

Write Data Block

The write data block transmits data to the single-port controller. The write data block maintains write data FIFO buffers and clock boundary crossing for the write data. The write data block informs the command block of the amount of pending write data for each transaction so that the command block can calculate eligibility for the next SDRAM write burst.

Read Data Block

The read data block receives data from the single-port controller. Depending on the port state, the read data block either buffers the data in its internal buffer or passes the data straight to the clock boundary crossing FIFO buffer. The read data block reorders out-of-order data for Avalon-MM ports.

In order to prevent the read FIFO buffer from overflowing, the read data block informs the command block of the available buffer area so the command block can pace read transaction dispatch.

Single-Port Controller

The single-port logic is responsible for following actions:

- Queuing the pending SDRAM bursts
- Choosing the most efficient burst to send next
- Keeping the SDRAM pipeline full
- Ensuring all SDRAM timing parameters are met

Transactions passed to the single-port logic for a single page in SDRAM are guaranteed to be executed in order, but transactions can be reordered between pages. Each SDRAM burst read or write is converted to the appropriate Altera PHY interface (AFI) command to open a bank on the correct row for the transaction (if required), execute the read or write command, and precharge the bank (if required).

The single-port logic implements command reordering (looking ahead at the command sequence to see which banks can be put into the correct state to allow a read or write command to be executed) and data reordering (allowing data transactions to be dispatched even if the data transactions are executed in an order different than they were received from the multi-port logic).

The single-port controller consists of eight sub-modules.

Command Generator

The command generator accepts commands from the MPFE and from the internal ECC logic, and provides those commands to the timer bank pool.

Timer Bank Pool

The timer bank pool is a parallel queue that operates with the arbiter to enable data reordering. The timer bank pool tracks incoming requests, ensures that all timing requirements are met, and, on receiving write-data-ready notifications from the write data buffer, passes the requests to the arbiter

Related Information

Memory Controller Architecture on page 11-6
For more information, refer to the SDRAM Controller Block diagram.

Arbiter

The arbiter determines the order in which requests are passed to the memory device. When the arbiter receives a single request, that request is passed immediately. When multiple requests are received, the arbiter uses arbitration rules to determine the order to pass requests to the memory device.

Related Information

Memory Controller Architecture on page 11-6
For more information, refer to the SDRAM Controller Block diagram.

Rank Timer

The rank timer performs the following functions:

- Maintains rank-specific timing information
- Ensures that only four activates occur within a specified timing window
- Manages the read-to-write and write-to-read bus turnaround time
- Manages the time-to-activate delay between different banks

Related Information

Memory Controller Architecture on page 11-6
For more information, refer to the SDRAM Controller Block diagram.

Write Data Buffer

The write data buffer receives write data from the MPFE and passes the data to the PHY, on approval of the write request.

Related Information

Memory Controller Architecture on page 11-6
For more information, refer to the SDRAM Controller Block diagram.

ECC Block

The ECC block consists of an encoder and a decoder-corrector, which can detect and correct single-bit errors, and detect double-bit errors. The ECC block can correct single- bit errors and detect double-bit errors resulting from noise or other impairments during data transmission.

Functional Description of the SDRAM Controller Subsystem

MPFE Operation Ordering

Operation ordering is defined and enforced within a port, but not between ports. All transactions received on a single port for overlapping addresses execute in order. Requests arriving at different ports have no guaranteed order of service, except when a first transaction has completed before the second arrives.

Avalon-MM does not support write acknowledgement. When a port is configured to support Avalon-MM, you should read from the location that was previously written to ensure that the write operation has completed. When a port is configured to support AXI, the master accessing the port can safely issue a read operation to the same address as a write operation as soon as the write has been acknowledged. To keep write latency low, writes are acknowledged as soon as the transaction order is guaranteed—meaning that any operations received on any port to the same address as the write operation are executed after the write operation.

To reduce read latency, the single-port logic can return read data out of order to the multi-port logic. The returned data is rearranged to its initial order on a per port basis by the multi-port logic and no traffic reordering occurs between individual ports.

Read Data Handling

The MPFE contains a read buffer shared by all ports. If a port is capable of receiving returned data then the read buffer is bypassed. If the size of a read transaction is smaller than twice the memory interface width, the buffer RAM cannot be bypassed. The lowest memory latency occurs when the port is ready to receive data and the full width of the interface is utilized.

MPFE Multi-Port Arbitration

The HPS SDRAM controller multi-port front end (MPFE) contains a programmable arbiter. The arbiter decides which MPFE port gains access to the single-port memory controller.

The SDRAM transaction size that is arbitrated is a burst of two beats. This burst size ensures that the arbiter does not favor one port over another when the incoming transaction size is a large burst.

The arbiter makes decisions based on two criteria: priority and weight. The priority is an absolute arbitration priority where the highest ports always win arbitration over the lower priority ports. Because multiple ports can be set to the same priority, the weight value refines the port choice by implementing a round-robin arbitration among ports set to the same priority. This programmable weight allows you to assign a higher arbitration value to a port in comparison to others such that the highest weighted port receives more transaction bandwidth than the lower weighted ports of the same priority.

Before arbitration is performed, the MPFE buffers are checked for any incoming transactions. The priority of each port that has buffered transactions is compared and the highest priority wins. If multiple ports are of the same highest priority value, the port weight is applied to determine which port wins. Because the arbiter only allows SDRAM-sized bursts into the single-port memory controller, large

transactions may need to be serviced multiple times before the read or write command is fully accepted to the single-port memory controller. The MPFE supports dynamic tuning of the priority and weight settings for each port, with changes committed into the SDRAM controller at fixed intervals of time.

Arbitration settings are applied to each port of the MPFE. The memory controller supports a mix of Avalon-MM and AXI protocols. As defined in the "Port Mappings" section, the Avalon-MM ports consume a single command port while the AXI ports consume a pair of command ports to support simultaneous read and write transactions. In total, there are ten command ports for the MPFE to arbitrate. The following table illustrates the command port mapping within the HPS as well as the ports exposed to the FPGA fabric.

Table 11-4: HPS SDRAM MPFE Command Port Mapping

Command Port	Allowed Functions	Data Size
0, 2, 4	FPGA fabric AXI read command ports FPGA fabric Avalon-MM read or write command ports	32-bit to 256-bit data
1, 3, 5	FPGA fabric AXI write command ports FPGA fabric Avalon-MM read or write command ports	
6	L3 AXI read command port	32-bit data
7	MPU AXI read command port	64-bit data
8	L3 AXI write command port	32-bit data
9	MPU AXI write command port	64-bit data

When the FPGA ports are configured for AXI, the command ports are always assigned in groups of two starting with even number ports 0, 2, or 4 assigned to the read command channel. For example, if you configure the first FPGA-to-SDRAM port as AXI and the second port as Avalon-MM, you can expect the following mapping:

- Command port 0 = AXI read
- Command port 1 = AXI write
- Command port 2 = Avalon-MM read and write

Setting the MPFE Priority

The priority of each of the ten command ports is configured through the `userpriority` field of the `mppriority` register. This 30-bit register uses 3 bits per port to configure the priority. The lowest priority is 0x0 and the highest priority is 0x7. The bits are mapped in ascending order with bits [2:0] assigned to command port 0 and bits [29:27] assigned to command port 9.

Setting the MPFE Static Weights

The static weight settings used in the round-robin command port priority scheme are programmed in a 128-bit field distributed among four 32-bit registers:

- `mpweight_0_4`
- `mpweight_1_4`
- `mpweight_2_4`
- `mpweight_3_4`

Each port is assigned a 5-bit value within the 128-bit field, such that port 0 is assigned to bits [4:0] of the `mpweight_0_4` register, port 1 is assigned to bits [9:5] of the `mpweight_0_4` register up to port 9, which is assigned to bits[49:45] contained in the `mpweight_1_4` register. The valid weight range for each port is 0x0 to 0x1F, with larger static weights representing a larger arbitration share.

Bits[113:50] in the `mpweight_1_4`, `mpweight_2_4` and `mpweight_3_4` registers, hold the sum of weights for each priority. This 64-bit field is divided into eight fields of 8-bits, each representing the sum of static weights. Bits[113:50] are mapped in ascending order with bits [57:50] holding the sum of static weights for all ports with priority setting 0x0, and bits [113:106] holding the sum of static weights for all ports with priority setting 0x7.

Example Using MPFE Priority and Weights

In this example, the following settings apply:

- FPGA MPFE ports 0 is assigned to AXI read commands and port 1 is assigned to AXI write commands.
- FPGA MPFE port 2 is assigned to Avalon-MM read and write commands.
- L3 master ports (ports 6 and 8) and the MPU ports (port 7 and 9) are given the lowest priority but the MPU ports are configured with more arbitration static weight than the L3 master ports.
- The FPGA MPFE command ports are given the highest priority; however, AXI ports 0 and 1 are given a larger static weight because they carry the highest priority traffic in the entire system. Assigning a high priority and larger static weight ensures ports 0 and 1 will receive the highest quality-of-service (QoS).

The table below details the port weights and sum of weights.

Table 11-5: SDRAM MPFE Port Priority, Weights and Sum of Weights

Priority	Weights										Sum of Weights
-	Port 0	Port 1	Port 2	Port 3	Port 4	Port 5	Port 6	Port 7	Port 8	Port 9	-
1	10	10	5	0	0	0	0	0	0	0	25
0	0	0	0	0	0	0	1	4	1	4	10

If the FPGA-to-SDRAM ports are configured according to the table and if both ports are accessed concurrently, you can expect the AXI port to receive 80% of the total service. This value is determined by taking the sum of port 0 and 1 weights divided by the total weight for all ports of priority 1. The remaining 20% of bandwidth is allocated to the Avalon-MM port. With these port settings, any FPGA transaction buffered by the MPFE for either slave port blocks the MPU and L3 masters from having their

buffered transactions serviced. To avoid transaction starvation, you should assign ports the same priority level and adjust the bandwidth allocated to each port by adjusting the static weights.

MPFE Weight Calculation

The MPFE applies a deficit round-robin arbitration scheme to determine which port is serviced. The larger the port weight, the more often it is serviced. Ports are serviced only when they have buffered transactions and are set to the highest priority of all the ports that also have buffered transactions. The arbiter determines which port to service by examining the running weight of all the same ports at the same priority level and the largest running weight is serviced.

Each time a port is drained of all transactions, its running weight is set to 0x80. Each time a port is serviced, the static weight is added and the sum of weights is subtracted from the running weight for that port. Each time a port is not serviced (same priority as another port but has a lower running weight), the static weight for the port is added to the running weight of the port for that particular priority level. The running weight additions and subtractions are only applied to one priority level, so any time ports of a different priority level are being serviced, the running weight of a lower priority port is not modified.

MPFE Multi-Port Arbitration Considerations for Use

When using MPFE multi-port arbitration, the following considerations apply:

- To ensure that the dynamic weight value does not roll over when a port is serviced, the following equation should always be true:

  ```
  (sum of weights - static weight) < 128
  ```

  If the running weight remains less than 128, arbitration for that port remains functional.
- The memory controller commits the priority and weight registers into the MPFE arbiter once every 10 SDRAM clock cycles. As a result, when the `mppriority` register and `mpweight_*_4` registers are configured at run time, the update interval can occur while the registers are still being written and ports can have different priority or weights than intended for a brief period. Because the `mppriority` and `mpweight_*_4` registers can be updated in a single 32-bit transaction, Altera recommends updating first to ensure that transactions that need to be serviced have the appropriate priority after the next update. Because the static weights are divided among four 32-bit registers
- In addition to the `mppriority` register and `mpweight_*_*` registers, the `remappriority` register adds another level of priority to the port scheduling. By programming bit N in the `priorityremap` field of the `remappriority` register, any port with an absolute priority N is sent to the front of the single port command queue and is serviced before any other transaction. Please refer to the `remappriority` register for more details.

The scheduler is work-conserving. Write operations can only be scheduled when enough data for the SDRAM burst has been received. Read operations can only be scheduled when sufficient internal memory is free and the port is not occupying too much of the read buffer.

Port Mappings on page 11-26
Refer to the "Port Mappings" section, for more information about command, read and write port assignments.

MPFE SDRAM Burst Scheduling

SDRAM burst scheduling recognizes addresses that access the same row/bank combination, known as open page accesses. Operations to a page are served in the order in which they are received by the single-port controller. Selection of SDRAM operations is a two-stage process. First, each pending transaction

must wait for its timers to be eligible for execution. Next, the transaction arbitrates against other transactions that are also eligible for execution.

The following rules govern transaction arbitration:

- High-priority operations take precedence over lower-priority operations
- If multiple operations are in arbitration, read operations have precedence over write operations
- If multiple operations still exist, the oldest is served first

A high-priority transaction in the SDRAM burst scheduler wins arbitration for that bank immediately if the bank is idle and the high-priority transaction's chip select, row, or column fields of the address do not match an address already in the single-port controller. If the bank is not idle, other operations to that bank yield until the high-priority operation is finished. If the chip select, row, and column fields match an earlier transaction, the high-priority transaction yields until the earlier transaction is completed.

Clocking

The FPGA fabric ports of the MPFE can be clocked at different frequencies. Synchronization is maintained by clock-domain crossing logic in the MPFE. Command ports can operate on different clock domains, but the data ports associated with a given command port must be attached to the same clock as that command port.

Note: A command port paired with a read and write port to form an Avalon-MM interface must operate at the same clock frequency as the data ports associated with it.

Single-Port Controller Operation

The single-port controller increases the performance of memory transactions through command and data re-ordering, enforcing bank policies, combining write operations and allowing burst transfers. Correction of single-bit errors and detection of double-bit errors is handled in the ECC module of the single-port Controller.

SDRAM Interface

The SDRAM interface is up to 40 bits wide and can accommodate 8-bit, 16-bit, 16-bit plus ECC, 32-bit, or 32-bit plus ECC configurations. The SDRAM interface supports LPDDR2, DDR2, and DDR3 memory protocols.

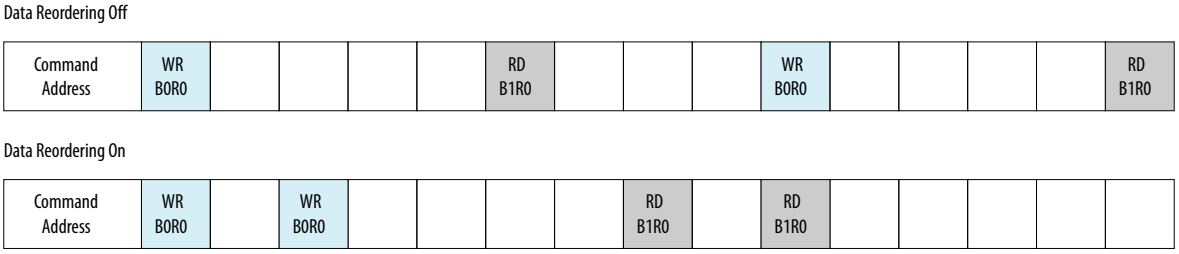
Command and Data Reordering

The heart of the SDRAM controller is a command and data reordering engine. Command reordering allows banks for future transactions to be opened before the current transaction finishes.

Data reordering allows transactions to be serviced in a different order than they were received when that new order allows for improved utilization of the SDRAM bandwidth. Operations to the same bank and row are performed in order to ensure that operations which impact the same address preserve the data integrity.

The following figure shows the relative timing for a write/read/write/read command sequence performed in order and then the same command sequence performed with data reordering. Data reordering allows the write and read operations to occur in bursts, without bus turnaround timing delay or bank reassignment.

Figure 11-3: Data Reordering Effect



The SDRAM controller schedules among all pending row and column commands every clock cycle.

Bank Policy

The bank policy of the SDRAM controller allows users to request that a transaction's bank remain open after an operation has finished so that future accesses do not delay in activating the same bank and row combination. The controller supports only eight simultaneously-opened banks, so an open bank might get closed if the bank resource is needed for other operations.

Open bank resources are allocated dynamically as SDRAM burst transactions are scheduled. Bank allocation is requested automatically by the controller when an incoming transaction spans multiple SDRAM bursts or by the extended command interface. When a bank must be reallocated, the least-recently-used open bank is used as the replacement.

If the controller determines that the next pending command will cause the bank request to not be honored, the bank might be held open or closed depending on the pending operation. A request to close a bank with a pending operation in the timer bank pool to the same row address causes the bank to remain open. A request to leave a bank open with a pending command to the same bank but a different row address causes a precharge operation to occur.

Write Combining

The SDRAM controller combines write operations from successive bursts on a port where the starting address of the second burst is one greater than the ending address of the first burst and the resulting burst length does not overflow the 11-bit burst-length counters.

Write combining does not occur if the previous bus command has finished execution before the new command has been received.

Burst Length Support

The controller supports burst lengths of 2, 4, 8, and 16, and data widths of 8, 16, and 32 bits for non-ECC operation, and widths of 24 and 40 operations with ECC enabled. The following table shows the type of SDRAM for each burst length.

Table 11-6: SDRAM Burst Lengths

Burst Length	SDRAM
4	LPDDR2, DDR2
8	DDR2, DDR3, LPDDR2

Burst Length	SDRAM
16	LPDDR2

Width Matching

The SDRAM controller automatically performs data width conversion.

ECC

The single-port controller supports memory ECC calculated by the controller. The controller ECC employs standard Hamming logic to detect and correct single-bit errors and detect double-bit errors. The controller ECC is available for 16-bit and 32-bit widths, each requiring an additional 8 bits of memory, resulting in an actual memory width of 24-bits and 40-bits, respectively.

Functions the controller ECC provides are:

- Byte Writes
- ECC Write Backs
- Notification of ECC Errors

Byte Writes

The memory controller performs a read-modify-write operation to ensure that the ECC data remains valid when a subset of the bits of a word is being written.

Byte writes with ECC enabled are executed as a read-modify-write. Typical operations only use a single entry in the timer bank pool. Controller ECC enabled sub-word writes use two entries. The first operation is a read and the second operation is a write. These two operations are transferred to the timer bank pool with an address dependency so that the write cannot be performed until the read data has returned. This approach ensures that any subsequent operations to the same address (from the same port) are executed after the write operation, because they are ordered on the row list after the write operation.

If an entire word is being written (but less than a full burst) and the DM pins are connected, no read is necessary and only that word is updated. If controller ECC is disabled, byte-writes have no performance impact.

ECC Write Backs

If the controller ECC is enabled and a read operation results in a correctable ECC error, the controller corrects the location in memory, if write backs are enabled. The correction results in scheduling a new read-modify-write.

A new read is performed at the location to ensure that a write operation modifying the location is not overwritten. The actual ECC correction operation is performed as a read-modify-write operation. ECC write backs are enabled and disabled through the `cfg_enable_ecc_code_overwrites` field in the `ctrlcfg` register.

User Notification of ECC Errors

When an ECC error occurs, an interrupt signal notifies the MPU subsystem, and the ECC error information is stored in the status registers. The memory controller provides interrupts for single-bit and double-bit errors.

The status of interrupts and errors are recorded in status registers, as follows:

- The `dramsts` register records interrupt status.
- The `dramintr` register records interrupt masks.
- The `sbecount` register records the single-bit error count.
- The `dbecount` register records the double-bit error count.
- The `erraddr` register records the address of the most recent error.

Related Information

Cortex-A9 Microprocessor Unit Subsystem on page 9-1
Information about ECC error interrupts

Interleaving Options

The controller supports the following address-interleaving options:

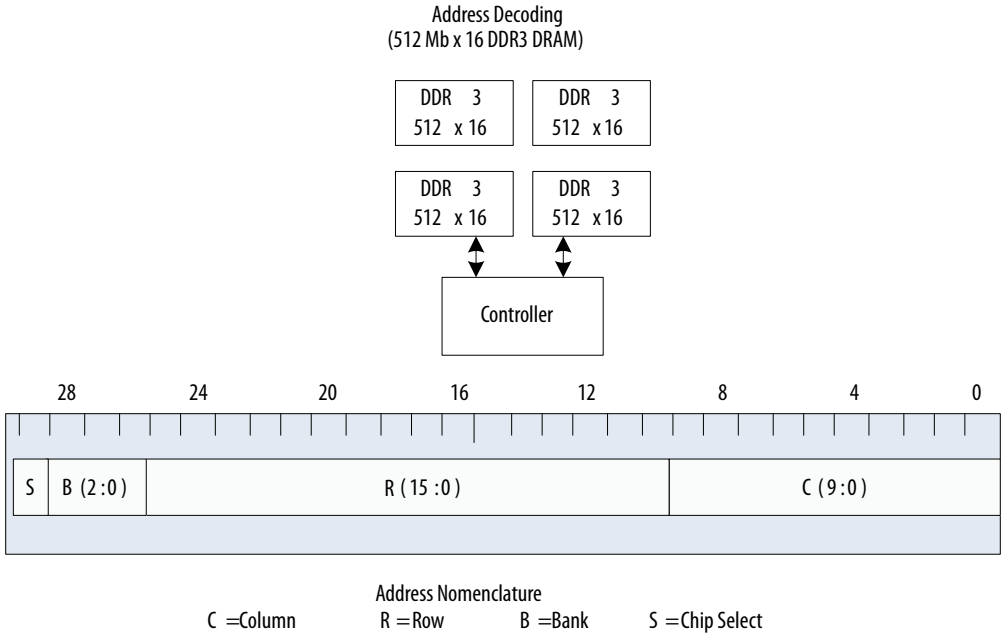
- Non-interleaved
- Bank interleave without chip select interleave
- Bank interleave with chip select interleave

The following interleaving examples use 512 megabits (Mb) x 16 DDR3 chips and are documented as byte addresses. For RAMs with smaller address fields, the order of the fields stays the same but the widths may change.

Non-interleaved

RAM mapping is non-interleaved.

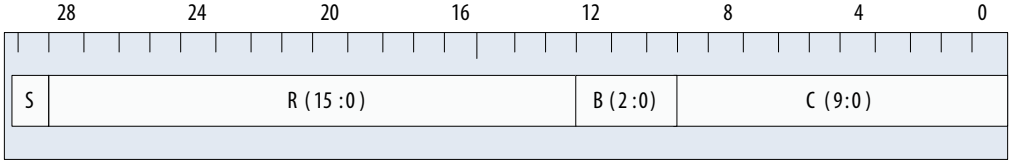
Figure 11-4: Non-interleaved Address Decoding



Bank Interleave Without Chip Select Interleave

Bank interleave without chip select interleave swaps row and bank from the non-interleaved address mapping. This interleaving allows smaller data structures to spread across all banks in a chip.

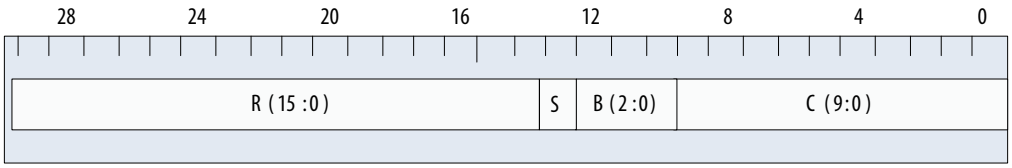
Figure 11-5: Bank Interleave Without Chip Select Interleave Address Decoding



Bank Interleave with Chip Select Interleave

Bank interleave with chip select interleave moves the row address to the top, followed by chip select, then bank, and finally column address. This interleaving allows smaller data structures to spread across multiple banks and chips (giving access to 16 total banks for multithreaded access to blocks of memory). Memory timing is degraded when switching between chips.

Figure 11-6: Bank Interleave With Chip Select Interleave Address Decoding



AXI-Exclusive Support

The single-port controller supports AXI-exclusive operations. The controller implements a table shared across all masters, which can store up to 16 pending writes. Table entries are allocated on an exclusive read and table entries are deallocated on a successful write to the same address by any master.

Any exclusive write operation that is not present in the table returns an exclusive fail as acknowledgement to the operation. If the table is full when the exclusive read is performed, the table replaces a random entry.

Note: When using AXI-exclusive operations, accessing the same location from Avalon-MM interfaces can result in unpredictable results.

Memory Protection

The single-port controller has address protection to allow the software to configure basic protection of memory from all masters in the system. If the system has been designed exclusively with AMBA masters, TrustZone® is supported. Ports that use Avalon-MM can be configured for port level protection.

Memory protection is based on physical addresses in memory. The single-port controller can configure up to 20 rules to allow or prevent masters from accessing a range of memory based on their AxIDs, level of security and the memory region being accessed. If no rules are matched in an access, then default settings take effect.

The rules are stored in an internal protection table and can be accessed through indirect addressing offsets in the `protruledwr` register in the CSR. To read a specific rule, set the `readrule` bit and write the appropriate offset in the `ruleoffset` field of the `protruledwr` register.

To write a new rule, three registers in the CSR must be configured:

1. The `protportdefault` register is programmed to control the default behavior of memory accesses when no rules match. When a bit is clear, all default accesses from that port pass. When a bit is set, all default accesses from that port fails. The bits are assigned as follows:

Table 11-7: `protportdefault` register

Bits	Description
`31:10`	reserved
`9`	When this bit is set to 1, deny CPU writes during a default transaction. When this bit is clear, allow CPU writes during a default transaction.
`8`	When this bit is set to 1, deny L3 writes during a default transaction. When this bit is clear, allow L3 writes during a default transaction.
`7`	When this bit is set to 1, deny CPU reads during a default transaction. When this bit is clear, allow CPU reads during a default transaction.

Bits	Description
6	When this bit is set to 1, deny L3 reads during a default transaction. When this bit is clear, allow L3 reads during a default transaction.
5:0	When this bit is set to 1, deny accesses from FPGA-to-SDRAM ports 0 through 5 during a default transaction. When this bit is clear, allow accesses from FPGA-to-SDRAM ports 0 through 5 during a default transaction.

2. The `protruleid` register gives the bounds of the AxID value that allows an access
3. The `protruledata` register configures the specific security characteristics for a rule.

Once the registers are configured, they can be committed to the internal protection table by programming the `ruleoffset` field and setting the `writerule` bit in the `protruledwr` register.

Secure and non-secure regions are specified by rules containing a starting address and ending address with 1 MB boundaries for both addresses. You can override the port defaults and allow or disallow all transactions.

The following table lists the fields that you can specify for each rule.

Table 11-8: Fields for Rules in Memory Protection Table

Field	Width	Description
Valid	1	Set to 1 to activate the rule. Set to 0 to deactivate the rule.
Port Mask (23)	10	Specifies the set of ports to which the rule applies, with one bit representing each port, as follows: bits 0 to 5 correspond to FPGA fabric ports 0 to 5, bit 6 corresponds to AXI L3 switch read, bit 7 is the CPU read, bit 8 is L3 switch write, and bit 9 is the CPU write.
AxID_low (23)	12	Low transfer AxID of the rules to which this rule applies. Incoming transactions match if they are greater than or equal to this value. Ports with smaller AxIDs have the AxID shifted to the lower bits and zero padded at the top.
AxID_high (23)	12	High transfer AxID of the rules to which this rule applies. Incoming transactions match if they are less than or equal to this value.
Address_low	12	Points to a 1MB block and is the lower address. Incoming addresses match if they are greater than or equal to this value.
Address_high	12	Upper limit of address. Incoming addresses match if they are less than or equal to this value.

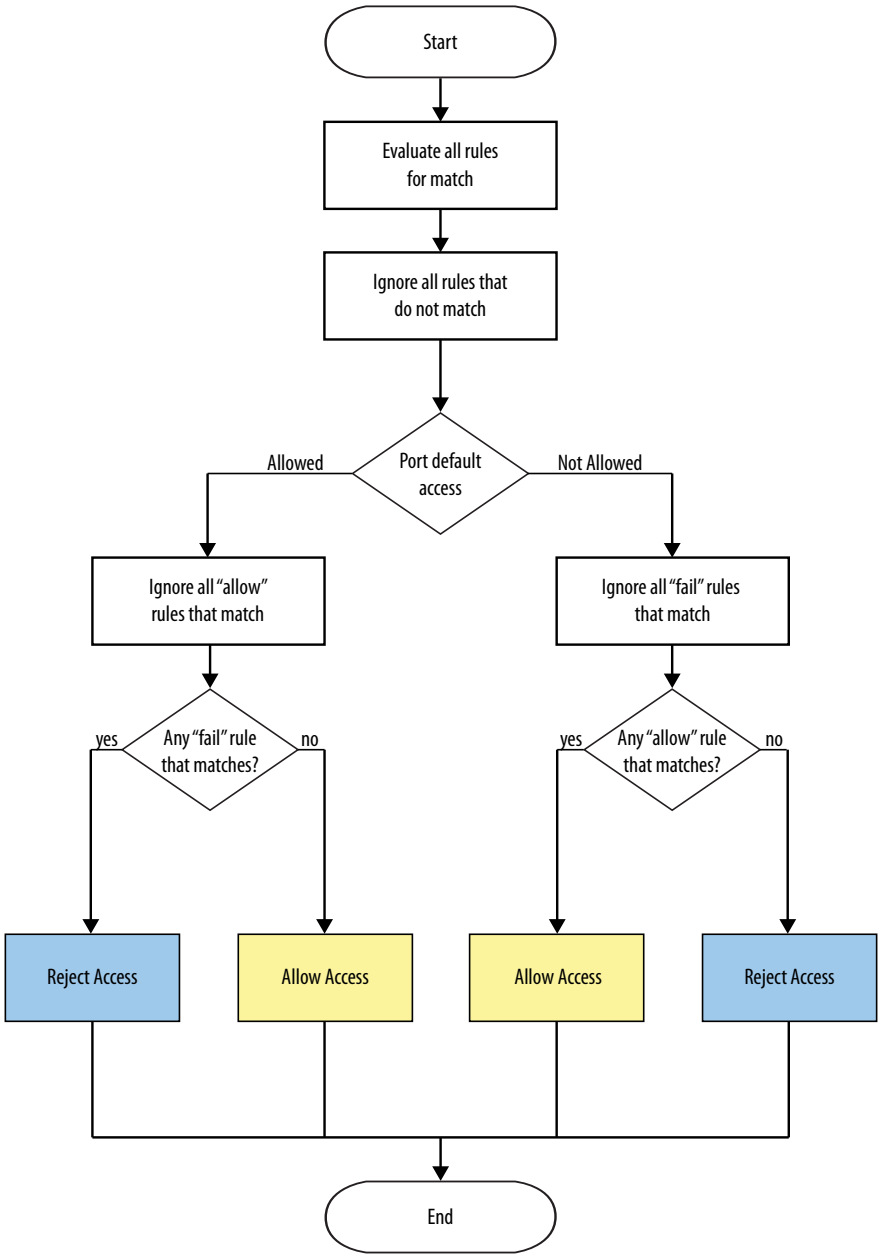
(23) Although AxID and Port Mask could be redundant, including both in the table allows possible compression of rules. If masters connected to a port do not have contiguous AxIDs, a port-based rule might be more efficient than an AxID-based rule, in terms of the number of rules needed.

Field	Width	Description
Protection	2	A value of 0x0 indicates that the protection bit is not set; a value of 0x1 sets the protection bit. Values 0x2 and 0x3 set the region to shared, meaning both secure and non-secure accesses are valid.
Fail/allow	1	Set this value to 1 to force the operation to fail or succeed.

A port has a default access status of either allow or fail, and rules with the opposite allow/fail value can override the default. The system evaluates each transaction against every rule in the memory protection table. A transaction received on a port, which by default allows access, would fail only if a rule with the fail bit matches the transaction. Conversely, a port, which by default prevents access, would allow access only if a rule allows that transaction to pass.

The following figure represents an overview of how the protection rules are applied. There is no concept of priority between the 20 rules and all rules are always evaluated in parallel.

Figure 11-7: SDRAM Protection Access Flow Diagram



Exclusive transactions are security checked on the read operation only. A write operation can occur only if a valid read is marked in the internal exclusive table. Consequently, a master performing an exclusive read followed by a write, can write to memory only if the exclusive read was successful.

Related Information

ARM TrustZone

For more information about TrustZone refer to the ARM web page.

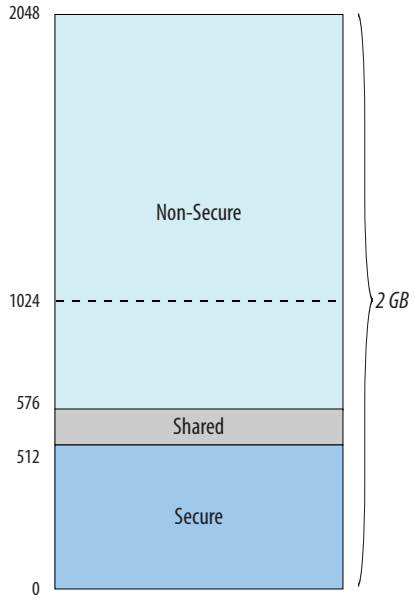
Example of Configuration for TrustZone

For a TrustZone configuration, memory isTrustZone divided into a range of memory accessible by secure masters and a range of memory accessible by non-secure masters. The two memory address ranges may have a range of memory that overlaps.

This example implements the following memory configuration:

- 2 GB total RAM size
- 0—512 MB dedicated secure area
- 513—576 MB shared area
- 577—2048 MB dedicated non-secure area

Figure 11-8: Example Memory Configuration



In this example, each port is configured by default to disallow all accesses. The following table shows the two rules programmed into the memory protection table.

Table 11-9: Rules in Memory Protection Table for Example Configuration

Rule #	Port Mask	AxID Low	AxID High	Address Low	Address High	protrule-data.security	Fail/Allow
1	0x3FF (1023)	0x000	0xFFF (4095)	0	576	0x1 (non-secure)	allow
2	0x3FF (1023)	0x000	0xFFF (4095)	512	2047	0x0 (secure)	allow

The port mask value, AxID Low, and AxID High, apply to all ports and all transfers within those ports. Each access request is evaluated against the memory protection table, and will fail unless there is a rule match allowing a transaction to complete successfully.

The following table shows the result for a sample set of transactions.

Table 11-10: Result for a Sample Set of Transactions

Operation	Source	Address Accesses	Security Access Type	Result	Comments
Read	CPU	4096	secure	Allow	Matches rule 1.
Write	CPU	536, 870, 912	secure	Allow	Matches rule 1.
Write	L3 attached masters	605, 028, 350	secure	Fail	Does not match rule 1 (out of range of the address field), does not match rule 2 (protection bit incorrect).
Read	L3 attached masters	4096	non-secure	Fail	Does not match rule 1 (AxPROT signal value wrong), does not match rule 2 (not in address range).
Write	CPU	536, 870, 912	non-secure	Allow	Matches rule 2.
Write	L3 attached masters	605, 028, 350	non-secure	Allow	Matches rule 2.

Note: If a master is using the Accelerator Coherency Port (ACP) to maintain cache coherency with the Cortex-A9 MPCore processor, then the address ranges in the rules of the memory protection table should be made mutually exclusive, such that the secure and non-secure regions do not overlap and any area that is shared is part of the non-secure region. This configuration prevents coherency issues from occurring.

SDRAM Power Management

The SDRAM controller subsystem supports the following power saving features in the SDRAM:

- Partial array self-refresh (PASR)
- Power down
- Deep power down for LPDDR2

To enable self-refresh for the memories of one or both chip selects, program the `selfshreq` bit and the `sefrfshmask` bit in the `lowpwreq` register.

Power-saving mode initiates either due to a user command or from inactivity. The number of idle clock cycles after which a memory can be put into power-down mode is programmed through the `autopdycycles` field of the `lowpwrtiming` register.

Power-down mode forces the SDRAM burst-scheduling bank-management logic to close all banks and issue the power down command. The SDRAM automatically reactivates when an active SDRAM command is received.

To enable deep power down request for the LPDDR2 memories of one or both chip selects, program the `deeppwrdnreq` bit and the `deepwrdnmask` field of the `lowpwreq` register.

Other power-down modes are performed only under user control.

DDR PHY

The DDR PHY connects the memory controller and external memory devices in the speed critical command path.

The DDR PHY implements the following functions:

- Calibration—the DDR PHY supports the JEDEC-specified steps to synchronize the memory timing between the controller and the SDRAM chips. The calibration algorithm is implemented in software.
- Memory device initialization—the DDR PHY performs the mode register write operations to initialize the devices. The DDR PHY handles re-initialization after a deep power down.
- Single-data-rate to double-data-rate conversion.

Clocks

All clocks are assumed to be asynchronous with respect to the `ddr_dqs_clk` memory clock. All transactions are synchronized to memory clock domain.

Table 11-11: SDRAM Controller Subsystem Clock Domains

Clock Name	Description
`ddr_dq_clk`	Clock for PHY
`ddr_dqs_clk`	Clock for MPFE, single-port controller, CSR access, and PHY
`ddr_2x_dqs_clk`	Clock for PHY that provides up to 2 times `ddr_dq_clk` frequency
`l4_sp_clk`	Clock for CSR interface
`mpu_l2_ram_clk`	Clock for MPU interface
`l3_main_clk`	Clock for L3 interface
`f2h_sdram_clk[5:0]`	Six separate clocks used for the FPGA-to-HPS SDRAM ports to the FPGA fabric

In terms of clock relationships, the FPGA fabric connects the appropriate clocks to write data, read data, and command ports for the constructed ports.

Related Information

Clock Manager on page 2-1

Resets

The SDRAM controller subsystem supports a full reset (cold reset) and a warm reset. The SDRAM controller can be configured to preserve memory contents during a warm reset.

To preserve memory contents, the reset manager can request that the single-port controller place the SDRAM in self-refresh mode prior to issuing the warm reset. If self-refresh mode is enabled before the warm reset to preserve memory contents, the PHY and the memory timing logic is not reset, but the rest of the controller is reset.

Related Information

Reset Manager on page 3-1

Taking the SDRAM Controller Subsystem Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the MPU boots up, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

Port Mappings

The memory interface controller has a set of command, read data, and write data ports that support AXI3, AXI4 and Avalon-MM. Tables are provided to identify port assignments and functions.

Table 11-12: Command Port Assignments

Command Port	Allowed Functions
0, 2, 4	FPGA fabric AXI read command ports FPGA fabric Avalon-MM read or write command ports
1, 3, 5	FPGA fabric AXI write command ports FPGA fabric Avalon-MM read or write command ports
6	L3 AXI read command port
7	MPU AXI read command port
8	L3 AXI write command port
9	MPU AXI write command port

Table 11-13: Read Port Assignments

Read Port	Allowed Functions
0, 1, 2, 3	64-bit read data from the FPGA fabric. When 128-bit data read ports are created, then read data ports 0 and1 get paired as well as 2 and 3.
4	32-bit L3 read data port
5	64-bit MPU read data port

Table 11-14: Write Port Assignments

Write Port	Allowed Functions
0, 1, 2, 3	64-bit write data from the FPGA fabric. When 128-bit data write ports are created, then write data ports 0 and 1 get paired as well as 2 and 3.
4	32-bit L3 write data port
5	64-bit MPU write data port

Initialization

The SDRAM controller subsystem has control and status registers (CSRs) which control the operation of the controller including DRAM type, DRAM timing parameters and relative port priorities. It also has a small set of bits which depend on the FPGA fabric to configure ports between the memory controller and the FPGA fabric; these bits are set for you when you configure your implementation using the HPS GUI in Qsys.

The CSRs are configured using a dedicated slave interface, which provides access to the registers. This region controls all SDRAM operation, MPFE scheduler configuration, and PHY calibration.

The FPGA fabric interface configuration is programmed into the FPGA fabric and the values of these register bits can be read by software. The ports can be configured without software developers needing to know how the FPGA-to-HPS SDRAM interface has been configured.

FPGA-to-SDRAM Protocol Details

The following topics summarize signals for the Avalon-MM Bidirectional port, Avalon-MM Write Port, Avalon-MM Read Port, and AXI port.

Note: If your device has multiple FPGA hardware images, then the same FPGA-to-SDRAM port configuration should be used across all designs.

Avalon-MM Bidirectional Port

The Avalon-MM bidirectional ports are standard Avalon-MM ports used to dispatch read and write operations.

Each configured Avalon-MM bidirectional port consists of the signals listed in the following table.

Table 11-15: Avalon-MM Bidirectional Port Signals

Name	Bit Width	Input/Output Direction	Function
clk	1	In	Clock for the Avalon-MM interface
read	1	In	Indicates read transaction (24)
write	1	In	Indicates write transaction (24)
address	32	In	Address of the transaction
readdata	32, 64, 128, or 256	Out	Read data return
readdatavalid	1	Out	Indicates the readdata signal contains valid data in response to a previous read request.
writedata	32, 64, 128, or 256	In	Write data for a transaction
byteenable	4, 8, 16, 32	In	Byte enables for each write byte lane
waitrequest	1	Out	Indicates need for additional cycles to complete a transaction
burstcount	11	In	Transaction burst length. The value of the maximum burstcount parameter must be a power of 2.

The read and write interfaces are configured to the same size. The byte-enable size scales with the data bus size.

Information about the Avalon-MM protocol

Avalon-MM Write-Only Port

The Avalon-MM write-only ports are standard Avalon-MM ports used to dispatch write operations. Each configured Avalon-MM write port consists of the signals listed in the following table.

(24) The Avalon-MM protocol does not allow read and write transactions to be posted concurrently.

Table 11-16: Avalon-MM Write-Only Port Signals

Name	Bits	Direction	Function
reset	1	In	Reset
clk	1	In	Clock
write	1	In	Indicates write transaction
address	32	In	Address of the transaction
writedata	32, 64, 128, or 256	In	Write data for a transaction
byteenable	4, 8, 16, 32	In	Byte enables for each write byte
waitrequest	1	Out	Indicates need for additional cycles to complete a transaction
burstcount	11	In	Transaction burst length

Related Information

Avalon Interface Specifications
Information about the Avalon-MM protocol

Avalon-MM Read Port

The Avalon-MM read ports are standard Avalon-MM ports used only to dispatch read operations. Each configured Avalon-MM read port consists of the signals listed in the following table.

Table 11-17: Avalon-MM Read Port Signals

Name	Bits	Direction	Function
reset	1	In	Reset
clk	1	In	Clock
read	1	In	Indicates read transaction
address	32	In	Address of the transaction
readdata	32, 64, 128, or 256	Out	Read data return

Name	Bits	Direction	Function
readdatavalid	1	Out	Flags valid cycles for read data return
waitrequest	1	Out	Indicates the need for additional cycles to complete a transaction. Needed for read operations when delay is needed to accept the read command.
burstcount	11	In	Transaction burst length

Related Information

Avalon Interface Specifications
Information about the Avalon-MM protocol

AXI Port

The AXI port uses an AXI-3 interface. Each configured AXI port consists of the signals listed in the following table. Each AXI interface signal is independent of the other interfaces for all signals, including clock and reset.

Table 11-18: AXI Port Signals

Name	Bits	Direction	Function
ARESETn	1	In	Reset
ACLK	1	In	Clock
Name	**Bits**	**Direction**	**Function**
Write Address Channel Signals			
AWID	4	In	Write identification tag
AWADDR	32	In	Write address
AWLEN	4	In	Write burst length
AWSIZE	3	In	Width of the transfer size
AWBURST	2	In	Burst type

Name	Bits	Direction	Function
AWLOCK	2	In	Lock type signal which indicates if the access is exclusive; valid values are 0x0 (normal access) and 0x1 (exclusive access)
AWCACHE	4	In	Cache policy type
AWPROT	3	In	Protection-type signal used to indicate whether a transaction is secure or non-secure
AWREADY	1	Out	Indicates ready for a write command
AWVALID	1	In	Indicates valid write command.
Name	**Bits**	**Direction**	**Function**
Write Data Channel Signals			
WID	4	In	Write data transfer ID
WDATA	32, 64, 128 or 256	In	Write data
WSTRB	4, 8, 16, 32	In	Byte-based write data strobe. Each bit width corresponds to 8 bit wide transfer for 32-bit wide to 256-bit wide transfer.
WLAST	1	In	Last transfer in a burst
WVALID	1	In	Indicates write data and strobes are valid
WREADY	1	Out	Indicates ready for write data and strobes
Name	**Bits**	**Direction**	**Function**
Write Response Channel Signals			
BID	4	Out	Write response transfer ID
BRESP	2	Out	Write response status

Name	Bits	Direction	Function
BVALID	1	Out	Write response valid signal
BREADY	1	In	Write response ready signal

Name	Bits	Direction	Function
Read Address Channel Signals			
ARID	4	In	Read identification tag
ARADDR	32	In	Read address
ARLEN	4	In	Read burst length
ARSIZE	3	In	Width of the transfer size
ARBURST	2	In	Burst type
ARLOCK	2	In	Lock type signal which indicates if the access is exclusive; valid values are 0x0 (normal access) and 0x1 (exclusive access)
ARCACHE	4	In	Lock type signal which indicates if the access is exclusive; valid values are 0x0 (normal access) and 0x1 (exclusive access)
ARPROT	3	In	Protection-type signal used to indicate whether a transaction is secure or non-secure
ARREADY	1	Out	Indicates ready for a read command
ARVALID	1	In	Indicates valid read command

Name	Bits	Direction	Function
Read Data Channel Signals			
RID	4	Out	Read data transfer ID

Name	Bits	Direction	Function
RDATA	32, 64, 128 or 256	Out	Read data
RRESP	2	Out	Read response status
RLAST	1	Out	Last transfer in a burs
RVALID	1	Out	Indicates read data is valid
RREADY	1	In	Read data channel ready signal

SDRAM Controller Subsystem Programming Model

SDRAM controller configuration occurs through software programming of the configuration registers using the CSR interface.

HPS Memory Interface Architecture

The configuration and initialization of the memory interface by the ARM processor is a significant difference compared to the FPGA memory interfaces, and results in several key differences in the way the HPS memory interface is defined and configured.

Boot-up configuration of the HPS memory interface is handled by the initial software boot code, not by the FPGA programmer, as is the case for the FPGA memory interfaces. The Quartus II software is involved in defining the configuration of I/O ports which is used by the boot-up code, as well as timing analysis of the memory interface. Therefore, the memory interface must be configured with the correct PHY-level timing information. Although configuration of the memory interface in Qsys is still necessary, it is limited to PHY- and board-level settings.

HPS Memory Interface Configuration

To configure the external memory interface components of the HPS, open the HPS interface by selecting the Arria V/Cyclone V Hard Processor System component in Qsys. Within the HPS interface, select the EMIF tab to open the EMIF parameter editor.

The EMIF parameter editor contains four additional tabs: PHY Settings, Memory Parameters, Memory Timing, and Board Settings. The parameters available on these tabs are similar to those available in the parameter editors for non-SoC device families.

There are significant differences between the EMIF parameter editor for the Hard Processor System and the parameter editors for non-SoC devices, as follows:

- Because the HPS memory controller is not configurable through the Quartus II software, the Controller and Diagnostic tabs, which exist for non-SoC devices, are not present in the EMIF parameter editor for the hard processor system.
- Unlike the protocol-specific parameter editors for non-SoC devices, the EMIF parameter editor for the Hard Processor System supports multiple protocols, therefore there is an SDRAM Protocol parameter, where you can specify your external memory interface protocol. By default, the EMIF parameter editor assumes the DDR3 protocol, and other parameters are automatically populated with DDR3-appropriate values. If you select a protocol other than DDR3, change other associated parameter values appropriately.
- Unlike the memory interface clocks in the FPGA, the memory interface clocks for the HPS are initialized by the boot-up code using values provided by the configuration process. You may accept the values provided by UniPHY, or you may use your own PLL settings. If you choose to specify your own PLL settings, you must indicate that the clock frequency that UniPHY should use is the requested clock frequency, and not the achieved clock frequency calculated by UniPHY.

Note: The HPS does not support EMIF synthesis generation, compilation, or timing analysis. The HPS hard memory controller cannot be bonded with another hard memory controller on the FPGA portion of the device.

HPS Memory Interface Simulation

Qsys provides a complete simulation model of the HPS memory interface controller and PHY, providing cycle-level accuracy, comparable to the simulation models for the FPGA memory interface.

The simulation model supports only the skip-cal simulation mode; quick-cal and full-cal are not supported. An example design is not provided, however you can create a test design by adding the traffic generator component to your design using Qsys. Also, the HPS simulation model does not use external memory pins to connect to the DDR memory model; instead, the memory model is incorporated directly into the HPS SDRAM interface simulation modules. The memory instance incorporated into the HPS model is in the simulation model hierarchy at: **hps_0/fpga_interfaces/f2sdram/hps_sdram_inst/mem/**

Simulation of the FPGA-to-SDRAM interfaces requires that you first bring the interfaces out of reset, otherwise transactions cannot occur. Connect the H2F reset to the F2S port resets and add a stage to your testbench to assert and deassert the H2F reset in the HPS. Appropriate Verilog code is shown below:

```
initial
begin
   // Assert reset
   <base name>.hps.fpga_interfaces.h2f_reset_inst.reset_assert();
   // Delay
   #1
   // Deassert reset
   <base name>.hps.fpga_interfaces.h2f_reset_inst.reset_deassert();
end
```

Generating a Preloader Image for HPS with EMIF

To generate a Preloader image for an HPS-based external memory interface, you must complete the following tasks:

- Create a Qsys project.
- Create a top-level file and add constraints.
- Create a Preloader BSP file.
- Create a Preloader image.

Creating a Qsys Project in Preparation for Generating a Preloader Image

This topic describes creating a Qsys project in preparation for generating a Preloader image.

1. On the **Tools** menu in the Quartus II software, click **Qsys**.
2. Under **Component library**, expand **Embedded Processor System**, select **Hard Processor System** and click **Add**.
3. Specify parameters for the **FPGA Interfaces**, **Peripheral Pin Multiplexing**, and **HPS Clocks**, based on your design requirements.
4. On the **SDRAM** tab, select the SDRAM protocol for your interface.
5. Populate the necessary parameter fields on the **PHY Settings**, **Memory Parameters**, **Memory Timing**, and **Board Settings** tabs.
6. Add other Qsys components in your Qsys design and make the appropriate bus connections.
7. Save the Qsys project.
8. Click **Generate** on the **Generation** tab, to generate the Qsys design.

Creating a Top-Level File and Adding Constraints

This topic describes adding your Qsys system to your top-level design and adding constraints to your design.

1. Add your Qsys system to your top-level design.
2. Add the Quartus II IP files (**.qip**) generated in step 2, to your Quartus II project.
3. Perform analysis and synthesis on your design.
4. Constrain your EMIF design by running the **<*variation_name*>_p0_pin_assignments.tcl** pin constraints script.
5. Add other necessary constraints—such as timing constraints, location assignments, and pin I/O standard assignments—for your design.
6. Compile your design to generate an SRAM object file (**.sof**) and the hardware handoff files necessary for creating a preloader image.

   Note: You must regenerate the hardware handoff files whenever the HPS configuration changes; for example, due to changes in Peripheral Pin Multiplexing or I/O standard for HPS pins.

Debugging HPS SDRAM in the Preloader

To assist in debugging your design, tools are available at the preloader stage.

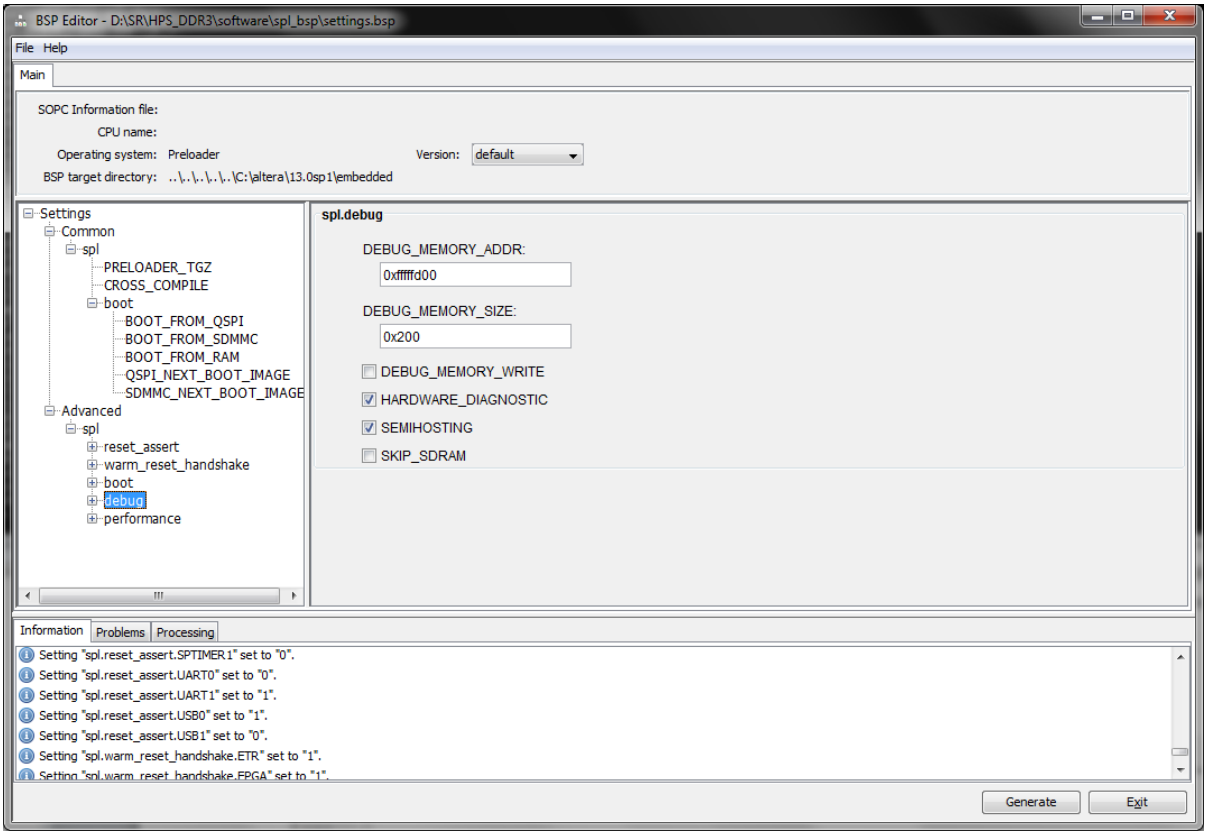
- UART or semihosting printout
- Simple memory test
- Debug report
- Predefined data patterns

The following topics provide procedures for implementing each of the above tools.

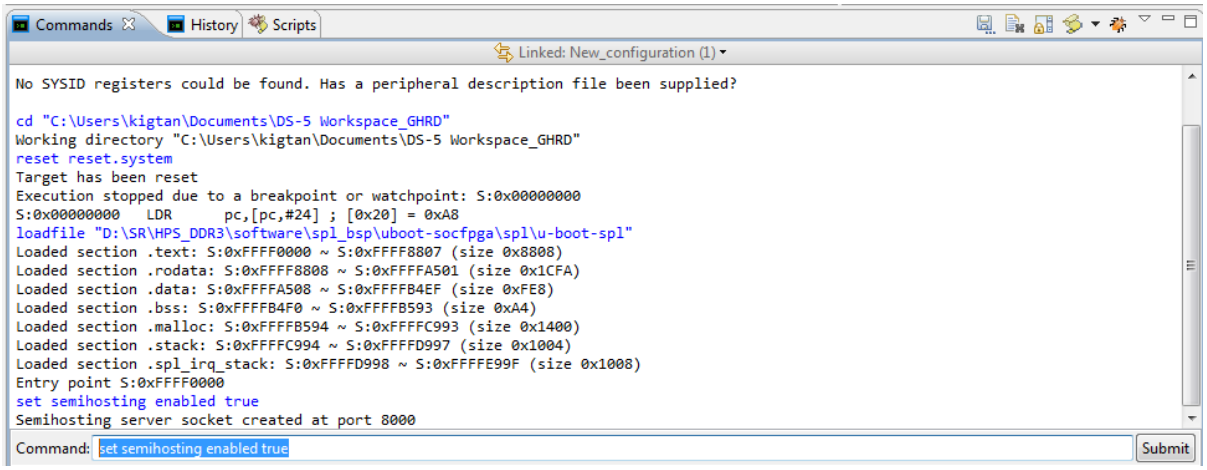
Enabling UART or Semihosting Printout

UART printout is enabled by default. If UART is not available on your system, you can use semihosting together with the debugger tool. To enable semihosting in the Preloader, follow these steps:

1. When you create the **.bsp** file in the BSP Editor, select **SEMIHOSTING** in the **spl.debug** window.



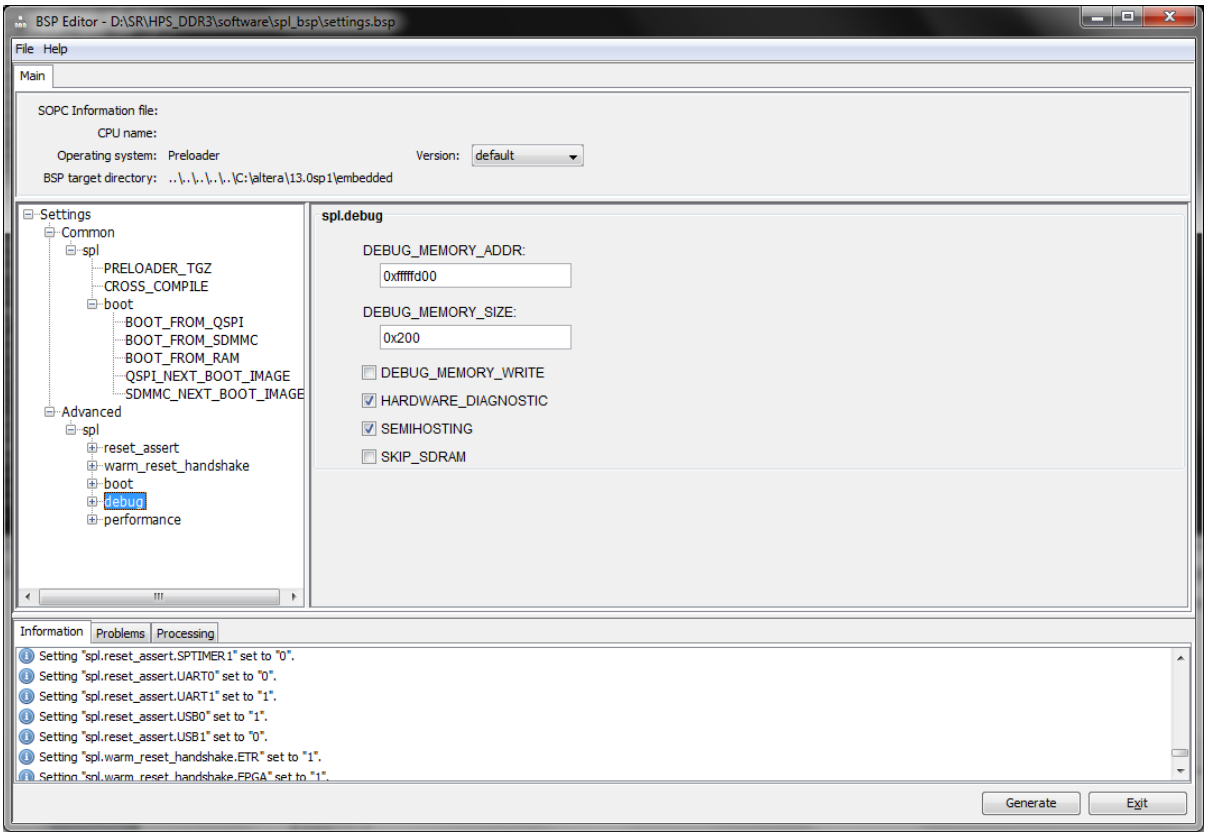
2. Enable semihosting in the debugger, by typing `set semihosting enabled true` at the command line in the debugger.



Enabling Simple Memory Test

After the SDRAM is successfully calibrated, a simple memory test may be performed using the debugger.

1. When you create the **.bsp** file in the BSP Editor, select **HARDWARE_DIAGNOSTIC** in the **spl.debug** window..



2. The simple memory test assumes SDRAM with a memory size of 1 GB. If your board contains a different SDRAM memory size, open the file ***<design folder>*\spl_bsp\uboot-socfpga\include\configs**

socfpga_cyclone5.h in a text editor, and change the `PHYS_SDRAM_1_SIZE` parameter at line 292 to specify your actual memory size in bytes.

socfpga_cyclone5.h

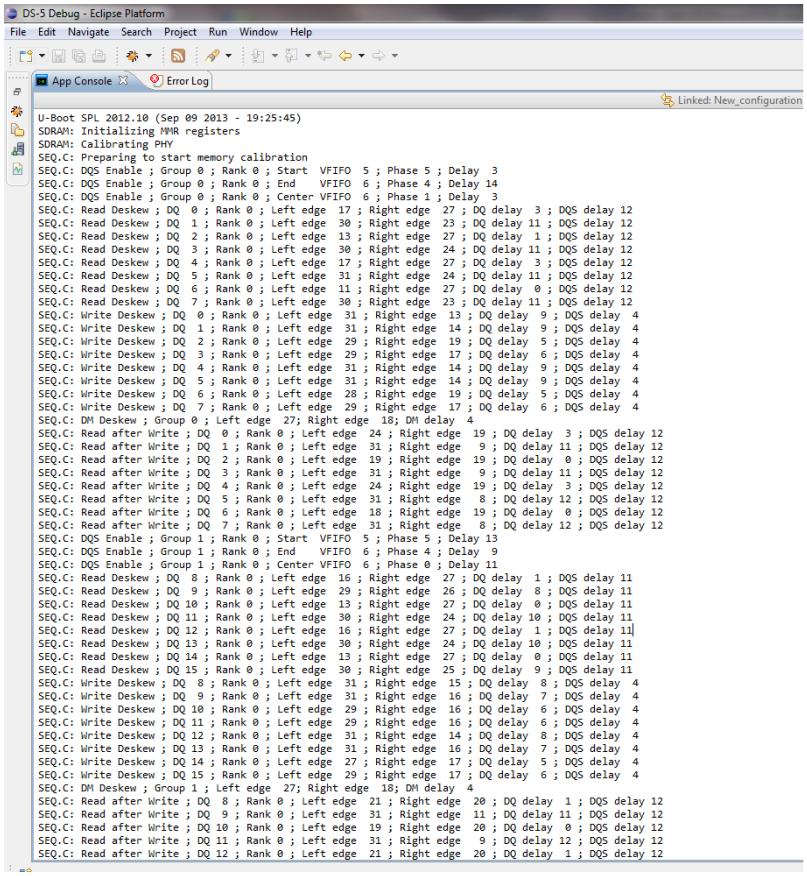
```
278   * Hardware drivers
279   */
280
281  /*
282   * SDRAM Memory Map
283   */
284  /* We have 1 bank of DRAM */
285  #define CONFIG_NR_DRAM_BANKS        1
286  /* SDRAM Bank #1 */
287  #define CONFIG_SYS_SDRAM_BASE       0x00000000
288  /* SDRAM memory size */
289  #ifdef CONFIG_SOCFPGA_VIRTUAL_TARGET
290  #define PHYS_SDRAM_1_SIZE       0x80000000
291  #else
292  #define PHYS_SDRAM_1_SIZE       0x40000000
293  #endif
294  /* SDRAM Bank #1 base address */
295  #define PHYS_SDRAM_1            CONFIG_SYS_SDRAM_BASE
296  /* memtest setup */
297  /* Begin and end addresses of the area used by the simple memory test.c */
298  #define CONFIG_SYS_MEMTEST_START    0x00000000
299  #define CONFIG_SYS_MEMTEST_END      PHYS_SDRAM_1_SIZE
300
```

Enabling the Debug Report

You can enable the SDRAM calibration sequencer to produce a debug report on the UART printout or semihosting output. To enable the debug report, follow these steps:

1. After you have enabled the UART or semihosting, open the file ***<project directory>*\hps_isw_handoff\sequencer_defines.h**in a text editor.
2. Locate the line `#define RUNTIME_CAL_REPORT 0` and change it to `#define RUNTIME_CAL_REPORT 1`.

Figure 11-9: Semihosting Printout With Debug Support Enabled



Analysis of Debug Report

The following analysis will help you interpret the debug report.

- The Read Deskew and Write Deskew results shown in the debug report are before calibration. (Before calibration results are actually from the window seen *during* calibration, and are most useful for debugging.)
- For each DQ group, the Write Deskew, Read Deskew, DM Deskew, and Read after Write results map to the before-calibration margins reported in the EMIF Debug Toolkit.

  Note: The Write Deskew, Read Deskew, DM Deskew, and Read after Write results are reported in delay steps (nominally 25ps, in Arria V and Cyclone V devices), not in picoseconds.
- DQS Enable calibration is reported as a VFIFO setting (in one clock period steps), a phase tap (in one-eighth clock period steps), and a delay chain step (in 25ps steps).

```
SEQ.C: DQS Enable ; Group 0 ; Rank 0 ; Start  VFIFO  5 ; Phase 6 ; Delay  4
SEQ.C: DQS Enable ; Group 0 ; Rank 0 ; End    VFIFO  6 ; Phase 5 ; Delay  9
SEQ.C: DQS Enable ; Group 0 ; Rank 0 ; Center VFIFO  6 ; Phase 2 ; Delay  1
```

  Analysis of DQS Enable results: A VFIFO tap is 1 clock period, a phase is 1/8 clock period (45 degrees) and delay is nominally 25ps per tap. The DQSen window is the difference between the start and end—for the above example, assuming a frequency of 400 MHz (2500ps), that calculates as follows: `start is 5*2500 + 6*2500/8 +4*25 = 14475ps`. By the same calculation, the end is 16788ps. Consequently, the DQSen window is 2313ps.
- The size of a read window or write window is equal to `(left edge + right edge) * delay chain step size`. Both the left edge and the right edge can be negative or positive.:

```
SEQ.C: Read Deskew  ; DQ  0 ; Rank 0 ; Left edge  18 ; Right edge  27 ; DQ
delay  0 ; DQS delay  8
SEQ.C: Write Deskew ; DQ  0 ; Rank 0 ; Left edge  30 ; Right edge  17 ; DQ
delay  6 ; DQS delay  4
```

  Analysis of DQ and DQS delay results: The DQ and DQS output delay (write) is the D5 delay chain. The DQ input delay (read) is the D1 delay chain, the DQS input delay (read) is the D4 delay chain.
- Consider the following example of latency results:

```
SEQ.C: LFIFO Calibration ; Latency 10
```

  Analysis of latency results: This is the calibrated PHY read latency. The EMIF Debug Toolkit does not report this figure. This latency is reported in clock cycles.
- Consider the following example of FOM results:

```
SEQ.C: FOM IN  = 83
SEQ.C: FOM OUT = 91
```

  Analysis of FOM results: The FOM IN value is a measure of the health of the read interface; it is calculated as the sum over all groups of the minimum margin on DQ plus the margin on DQS, divided by 2. The FOM OUT is a measure of the health of the write interface; it is calculated as the sum over all groups of the minimum margin on DQ plus the margin on DQS, divided by 2. You may refer to these values as indicators of improvement when you are experimenting with various termination schemes, assuming there are no individual misbehaving DQ pins.
- The debug report does not provide delay chain step size values. The delay chain step size varies with device speed grade. Refer to your device data sheet for exact incremental delay values for delay chains.

Writing a Predefined Data Pattern to SDRAM in the Preloader

You can include your own code to write a predefined data pattern to the SDRAM in the preloader for debugging purposes.

1. Include your code in the file: **<*project_folder*>\software\spl_bsp\uboot-socfpga\arch\arm\cpu\armv7\socfpga\spl.c** .
   Adding the following code to the **spl.c** file causes the controller to write walking 1s and walking 0s, repeated five times, to the SDRAM.

```
/*added for demo, place after the last #define statement in spl.c */
#define ROTATE_RIGHT(X) ( (X>>1) | (X&1?0X80000000:0) )
/*added for demo, place after the calibration code */
 test_data_walk0((long *)0x100000,PHYS_SDRAM_1_SIZE);
int test_data_walk0(long *base, long maxsize)
{
    volatile long *addr;
    long          cnt;
    ulong          data_temp[3];
        ulong          expected_data[3];
    ulong          read_data;
        int           i = 0;  //counter to loop different data pattern
        int          num_address;

       num_address=50;

       data_temp[0]=0XFFFFFFFE; //initial data for walking 0 pattern
       data_temp[1]=0X00000001; //initial data for walking 1 pattern
       data_temp[2]=0XAAAAAAAA; //initial data for A->5 switching

       expected_data[0]=0XFFFFFFFE; //initial data for walking 0 pattern
       expected_data[1]=0X00000001; //initial data for walking 1 pattern
       expected_data[2]=0XAAAAAAAA; //initial data for A->5 switching

       for (i=0;i<3;i++) {

    printf("\nSTARTED %08X DATA PATTERN !!!!\n",data_temp[i]);
    /*write*/
    for (cnt = (0+i*num_address); cnt < ((i+1)*num_address) ;  cnt++ ) {
        addr = base + cnt;    /* pointer arith! */
        sync ();
            *addr = data_temp[i];
        data_temp[i]=ROTATE_RIGHT(data_temp[i]);

        }

    /*read*/
    for (cnt = (0+i*num_address); cnt < ((i+1)*num_address) ; cnt = cnt++ ) {
        addr = base + cnt;    /* pointer arith! */
        sync ();
        read_data=*addr;
              printf("Address:%X  Expected: %08X    Read:%08X \n",addr,
expected_data[i],read_data);
               if (expected_data[i] !=read_data) {
                puts("!!!!!!FAILED!!!!!!\n\n");
        hang();
            }
                expected_data[i]=ROTATE_RIGHT(expected_data[i]);
}
}
}
====//End Of Code//=====
```

SDRAM Controller Module Register Descriptions

Address map for the SDRAM controller and multi-port front-end. All registers in this group reset to zero.

Offset: 0x5000

ctrlcfg on page 11-46
The Controller Configuration Register determines the behavior of the controller.

dramtiming1 on page 11-48
This register implements JEDEC standardized timing parameters. It should be programmed in clock cycles, for the value specified by the memory vendor.

dramtiming2 on page 11-49
This register implements JEDEC standardized timing parameters. It should be programmed in clock cycles, for the value specified by the memory vendor.

dramtiming3 on page 11-50
This register implements JEDEC standardized timing parameters. It should be programmed in clock cycles, for the value specified by the memory vendor.

dramtiming4 on page 11-51
This register implements JEDEC standardized timing parameters. It should be programmed in clock cycles, for the value specified by the memory vendor.

lowpwrtiming on page 11-51
This register controls the behavior of the low power logic in the controller.

dramodt on page 11-52
This register controls which ODT pin asserts with chip select 0 (CS0) assertion and which ODT pin asserts with chip select 1 (CS1) assertion.

protruleaddr on page 11-65
This register is used to control the memory protection for port 0 transactions. Address ranges can either be used to allow access to memory regions or disallow access to memory regions. If TrustZone is being used, access can be enabled for protected transactions or disabled for unprotected transactions. The default state of this register is to allow all access. Address values used for protection are only physical addresses.

protruleid on page 11-66
This register configures the AxID for a given protection rule.

protruledata on page 11-67
This register configures the protection memory characteristics of each protection rule.

protrulerdwr on page 11-67
This register is used to perform read and write operations to the internal protection table.

mppriority on page 11-68
This register is used to configure the DRAM burst operation scheduling.

remappriority on page 11-69
This register applies another level of port priority after a transaction is placed in the single port queue.

Port Sum of Weight Register Register Descriptions on page 11-70
This register is used to configure the DRAM burst operation scheduling.

ctrlcfg

The Controller Configuration Register determines the behavior of the controller.

Module Instance	Base Address	Register Address

ctrlcfg Fields

Bit	Name	Description	Access	Reset
25	bursttermen	Set to a one to enable the controller to issue burst terminate commands. This must only be set when the DRAM memory type is LPDDR2.	RW	0x0
24	burstintren	Set to a one to enable the controller to issue burst interrupt commands. This must only be set when the DRAM memory type is LPDDR2.	RW	0x0
23	nodmpins	Set to a one to enable DRAM operation if no DM pins are connected.	RW	0x0
22	dqstrken	Enables DQS tracking in the PHY.	RW	0x0
21:16	starvelimit	Specifies the number of DRAM burst transactions an individual transaction will allow to reorder ahead of it before its priority is raised in the memory controller.	RW	0x0
15	reorderen	This bit controls whether the controller can re-order operations to optimize SDRAM bandwidth. It should generally be set to a one.	RW	0x0
14	gendbe	Enable the deliberate insertion of double bit errors in data written to memory. This should only be used for testing purposes.	RW	0x0
13	gensbe	Enable the deliberate insertion of single bit errors in data written to memory. This should only be used for testing purposes.	RW	0x0
12	cfg_enable_ecc_code_overwrites	Set to a one to enable ECC overwrites. ECC overwrites occur when a correctable ECC error is seen and cause a new read/modify/write to be scheduled for that location to clear the ECC error.	RW	0x0
11	ecccorren	Enable auto correction of the read data returned when single bit error is detected.	RW	0x0
10	eccen	Enable the generation and checking of ECC. This bit must only be set if the memory connected to the SDRAM interface is 24 or 40 bits wide. If you set this, you must clear the useeccasdata field in the staticcfg register.	RW	0x0

Bit	Name	Description	Access	Reset
9:8	addrorder	This bit field selects the order for address interleaving. Programming this field with different values gives different mappings between the AXI or Avalon-MM address and the SDRAM address. Program this field with the following binary values to select the ordering. **Value** — **Description** 0x0 — chip, row, bank, column 0x1 — chip, bank, row, column 0x2 — row, chip, bank, column 0x3 — reserved	RW	0x0
7:3	membl	This bit field configures burst length as a static decimal RW 0x0 value. These values are valid for JEDEC allowed DRAMs configured by programming the memtype field. The membl field is programmed as follows: For DDR3, program membl to 0x8; for DDR2, membl can be 0x4 or 0x8, depending on the DRAM chip; for LPDDR2, membl can be programmed with 0x4, 0x8 or 0x10; for LPDDR, membl can be 0x2, 0x4 or 0x8.	RW	0x0
2:0	memtype	This bit field selects the memory type. This field can be programmed with the following binary values: **Value** — **Description** 0x0 — Reserved 0x1 — Memory type is DDR2 SDRAM 0x2 — Memory type is DDR3 SDRAM 0x3 — reserved 0x4 — Memory type is LPDDR2 SDRAM 0x5-0x7 — Reserved	RW	0x0

dramtiming1

This register implements JEDEC standardized timing parameters. It should be programmed in clock cycles, for the value specified by the memory vendor.

dramtiming4 Fields

Bit	Name	Description	Access	Reset
23:20	minpwrsavecycles	The minimum number of cycles to stay in a low power state. This applies to both power down and self-refresh and should be set to the greater of tPD and tCKESR.	RW	0x0
19:10	pwrdownexit	The power down exit cycles, tXPDLL.	RW	0x0
9:0	selfrfshexit	The self refresh exit cycles, tXS.	RW	0x0

lowpwrtiming

This register controls the behavior of the low power logic in the controller.

Module Instance	Base Address	Register Address
sdr	0xFFC20000	0xFFC25014

Offset: 0x5014

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved												clkdisablecycles RW 0x0			
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
autopdcycles RW 0x0															

lowpwrtiming Fields

Bit	Name	Description	Access	Reset
19:16	clkdisablecycles	Set to a the number of clocks after the execution of an self-refresh to stop the clock. This register is generally set based on PHY design latency and should generally not be changed.	RW	0x0
15:0	autopdcycles	The number of idle clock cycles after which the controller should place the memory into power-down mode.	RW	0x0

dramodt

This register controls which ODT pin asserts with chip select 0 (CS0) assertion and which ODT pin asserts with chip select 1 (CS1) assertion.

Module Instance	Base Address	Register Address
sdr	0xFFC20000	0xFFC25018

Offset: 0x5018

Access: RW

Bit Fields

Reserved								cfg_read_odt_chip RW 0x0				cfg_write_odt_chip RW 0x0			

dramodt Fields

Bit	Name	Description	Access	Reset
7:4	cfg_read_odt_chip	This register controls which ODT pin is asserted during reads. Bits[5:4] select the ODT pin that asserts with CS0 and bits[7:6] select the ODT pin that asserts with CS1. For example, a value of 0x9 asserts ODT[0] for accesses CS0 and ODT[1] for accesses with CS1. This field can be set to 0x1 is there is only one chip select available.	RW	0x0
3:0	cfg_write_odt_chip	This register controls which ODT pin is asserted during writes. Bits[1:0] select the ODT pin that asserts with CS0 and bits[3:2] select the ODT pin that asserts with CS1. For example, a value of 0x9 asserts ODT[0] for accesses CS0 and ODT[1] for accesses with CS1. This field can be set to 0x1 is there is only one chip select available.	RW	0x0

dramaddrw

This register configures the width of the various address fields of the DRAM. The values specified in this register must match the memory devices being used.

Module Instance	Base Address	Register Address
sdr	0xFFC20000	0xFFC2502C

Offset: 0x502C

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

csbits RW 0x0			bankbits RW 0x0			rowbits RW 0x0					colbits RW 0x0				

dramaddrw Fields

Bit	Name	Description	Access	Reset
15:13	csbits	The number of chip select address bits for the memory devices in your memory interface.	RW	0x0
12:10	bankbits	The number of bank address bits for the memory devices in your memory interface.	RW	0x0
9:5	rowbits	The number of row address bits for the memory devices in your memory interface.	RW	0x0

Bit	Name	Description	Access	Reset
4:0	colbits	The number of column address bits for the memory devices in your memory interface.	RW	0x0

dramifwidth

This register controls the interface width of the SDRAM controller.

Module Instance	Base Address	Register Address
sdr	0xFFC20000	0xFFC25030

Offset: 0x5030

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved								ifwidth RW 0x0							

dramifwidth Fields

Bit	Name	Description	Access	Reset
7:0	ifwidth	This register controls the width of the SDRAM interface, including any bits used for ECC. For example, for a 32-bit interface with ECC, program this register to 0x28. The ctrlwidth register must also be programmed.	RW	0x0

dramsts

This register provides the status of the calibration and ECC logic.

Module Instance	Base Address	Register Address
sdr	0xFFC20000	0xFFC25038

Offset: 0x5038

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved

Reserved											corrdrop RW 0x0	dbeerr RW 0x0	sbeerr RW 0x0	calfail RW 0x0	calsuccess RW 0x0

dramsts Fields

Bit	Name	Description	Access	Reset
4	corrdrop	This bit is set to 1 when any auto-corrections have been dropped.	RW	0x0
3	dbeerr	This bit is set to 1 when any ECC double bit errors are detected.	RW	0x0
2	sbeerr	This bit is set to 1 when any ECC single bit errors are detected.	RW	0x0
1	calfail	This bit is set to 1 when the PHY is unable to calibrate.	RW	0x0
0	calsuccess	This bit will be set to 1 if the PHY was able to successfully calibrate.	RW	0x0

dramintr

This register can enable, disable and clear the SDRAM error interrupts.

Module Instance	Base Address	Register Address
sdr	0xFFC20000	0xFFC2503C

Offset: 0x503C

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved

Reserved											intrclr RW 0x0	corrdropmask RW 0x0	dbemask RW 0x0	sbemask RW 0x0	intren RW 0x0

dramintr Fields

Bit	Name	Description	Access	Reset
4	intrclr	Writing to this self-clearing bit clears the interrupt signal. Writing to this bit also clears the error count and error address registers: sbecount, dbecount, dropcount, erraddr, and dropaddr.	RW	0x0
3	corrdropmask	Set this bit to a one to mask interrupts for an ECC correction write back needing to be dropped. This indicates a burst of memory errors in a short period of time.	RW	0x0
2	dbemask	Mask the double bit error interrupt.	RW	0x0
1	sbemask	Mask the single bit error interrupt.	RW	0x0
0	intren	Enable the interrupt output.	RW	0x0

sbecount

This register tracks the single-bit error count.

Module Instance	Base Address	Register Address
sdr	0xFFC20000	0xFFC25040

Offset: 0x5040

Access: RW

Bit Fields

Reserved								corrdropcount RW 0x0							

dropcount Fields

Bit	Name	Description	Access	Reset
7:0	corrdropcount	This gives the count of the number of ECC write back transactions dropped due to the internal FIFO overflowing.	RW	0x0

dropaddr

This register holds the last dropped address.

Module Instance	Base Address	Register Address
sdr	0xFFC20000	0xFFC25050

Offset: 0x5050

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
corrdropaddr RW 0x0															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
corrdropaddr RW 0x0															

dropaddr Fields

Bit	Name	Description	Access	Reset
31:0	corrdropaddr	This register gives the last address which was dropped.	RW	0x0

lowpwreq

This register instructs the controller to put the DRAM into a power down state. Note that some commands are only valid for certain memory types.

Module Instance	Base Address	Register Address
sdr	0xFFC20000	0xFFC25054

Offset: 0x5054

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved										selfrfshmask RW 0x0		selfrshreq RW 0x0	deeppwrdnmask RW 0x0		deeppwrdnreq RW 0x0

lowpwreq Fields

Bit	Name	Description	Access	Reset
5:4	selfrfshmask	Write a one to each bit of this field to have a self refresh request apply to both chips.	RW	0x0
3	selfrshreq	Write a one to this bit to request the RAM be put into a self refresh state. This bit is treated as a static value so the RAM will remain in self-refresh as long as this register bit is set to a one. This power down mode can be selected for all DRAMs supported by the controller.	RW	0x0
2:1	deeppwrdnmask	Write ones to this register to select which DRAM chip selects will be powered down. Typical usage is to set both of these bits when deeppwrdnreq is set but the controller does support putting a single chip into deep power down and keeping the other chip running.	RW	0x0

Bit	Name	Description	Access	Reset
0	deeppwrdnreq	Write a one to this bit to request a deep power down. This bit should only be written with LPDDR2 DRAMs, DDR3 DRAMs do not support deep power down.	RW	0x0

lowpwrack

This register gives the status of the power down commands requested by the Low Power Control register.

Module Instance	Base Address	Register Address
sdr	0xFFC20000	0xFFC25058

Offset: 0x5058

Access: RW

staticcfg Fields

Bit	Name	Description	Access	Reset
3	applycfg	Write with this bit set to apply all the settings loaded in SDR registers to the memory interface. This bit is write-only and always returns 0 if read.	RW	0x0
2	useeccasdata	This field allows the FPGA ports to directly access the extra data bits that are normally used to hold the ECC code. The interface width must be set to 24 or 40 in the dramifwidth register. If you set this, you must clear the eccen field in the ctrlcfg register.	RW	0x0
1:0	membl	This bit field configures the DRAM burst length. For DDR3, program membl to 0x8; for DDR2, membl can be 0x4 or 0x8, depending on the DRAM chip; for LPDDR2, membl can be programmed with 0x4, 0x8 or 0x10; for LPDDR, membl can be 0x2, 0x4 or 0x8. If this field is programmed, the membl field in the ctrlcfg register must also be programmed.	RW	0x0

ctrlwidth

This register controls the width of the physical DRAM interface.

Module Instance	Base Address	Register Address
sdr	0xFFC20000	0xFFC25060

Offset: 0x5060

Access: RW

Bit Fields

Reserved														ctrlwidth RW 0x0	

ctrlwidth Fields

Bit	Name	Description	Access	Reset
1:0	ctrlwidth	This field specifies the SDRAM controller interface width: **Value** **Description** 0x0 8-bit interface width 0x1 16-bit (no ECC) or 24-bit (ECC enabled) interface width 0x2 32-bit (no ECC) or 40-bit (ECC enabled) interface width Additionally, you must program the dramifwidth register.	RW	0x0

portcfg

Each bit of the autopchen field maps to one of the control ports. If a port executes mostly sequential memory accesses, the corresponding autopchen bit should be 0. If the port has highly random accesses, then its autopchen bit should be set to 1.

Module Instance	Base Address	Register Address
sdr	0xFFC20000	0xFFC2507C

Offset: 0x507C

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved												autopchen RW 0x0			
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
autopchen RW 0x0						Reserved									

portcfg Fields

Bit	Name	Description	Access	Reset
19:10	autopchen	Auto-Precharge Enable: One bit is assigned to each control port. For each bit, the encodings are as follows: **Value** **Description** 0x0 The controller requests an automatic precharge following a bus command completion (close the row automatically) 0x1 The controller attempts to keep a row open. All active ports with random dominated operations should set the autopchen bit to 1.	RW	0x0

fpgaportrst

This register implements functionality to allow the CPU to control when the MPFE will enable the ports to the FPGA fabric.

Module Instance	Base Address	Register Address
sdr	0xFFC20000	0xFFC25080

Offset: 0x5080

Access: RW

Bit Fields															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
Reserved															
15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Reserved		portrstn RW 0x0													

fpgaportrst Fields

Bit	Name	Description	Access	Reset
13:0	portrstn	This register should be written to with a 1 to enable the selected FPGA port to exit reset. Writing a bit to a zero will stretch the port reset until the register is written. Read data ports are connected to bits 3:0, with read data port 0 at bit 0 to read data port 3 at bit 3. Write data ports 0 to 3 are mapped to 4 to 7, with write data port 0 connected to bit 4 to write data port 3 at bit 7. Command ports are connected to bits 8 to 13, with command port 0 at bit 8 to command port 5 at bit 13. Expected usage would be to set all the bits at the same time but setting some bits to a zero and others to a one is supported.	RW	0x0

protportdefault

This register controls the default protection assignment for a port. Ports which have explicit rules which define regions which are illegal to access should set the bits to pass by default. Ports which have explicit rules which define legal areas should set the bit to force all transactions to fail. Leaving this register to all zeros should be used for systems which do not desire any protection from the memory controller.

Module Instance	Base Address	Register Address
sdr	0xFFC20000	0xFFC2508C

Offset: 0x508C

Access: RW

Document Revision History

Date	Version	Changes
December 2014	2014.12.15	• Added SDRAM Protection Access Flow Diagram to "Memory Protection" subsection in the "Single-Port Controller Operation" section. • Changed the "SDRAM Multi-Port Scheduling" section to "SDRAM Multi-Port Arbitration" and added detailed information on how to use and program the priority and weighted arbitration scheme.
June 2014	2014.6.30	• Added *Port Mappings* section. • Added *SDRAM Controller Memory Options* section. • Enhanced *Example of Configuration for TrustZone* section. • Added SDRAM Controller address map and registers.
December 2013	2013.12.30	• Added *Generating a Preloader Image for HPS with EMIF* section. • Added *Debugging HPS SDRAM in the Preloader* section. • Enhanced *Simulation* section.
November 2012	1.1	Added address map and register definitions section.
January 2012	1.0	Initial release.

On-Chip Memory 12

2014.12.15

av_5v4 Subscribe Send Feedback

The hard processor system (HPS) contains two types of on-chip memory. The on-chip memory types are:

- On-Chip RAM—The on-chip RAM provides 64 KB of general-purpose RAM.
- Boot ROM—The boot ROM contains the code required to boot the HPS from cold or warm reset.

Both on-chip memories connect to the level 3 (L3) interconnect.

Related Information

- **On-Chip RAM** on page 12-1
- **Boot ROM** on page 12-3

On-Chip RAM

Features of the On-Chip RAM

The on-chip RAM offers the following features:

- 64-bit slave interface
- 64 KB size
- Single-ported RAM
- Read acceptance of two, write acceptance of two, and a total acceptance of four
- Error correction code (ECC) support
- High throughput - read or write every clock cycle.

Related Information

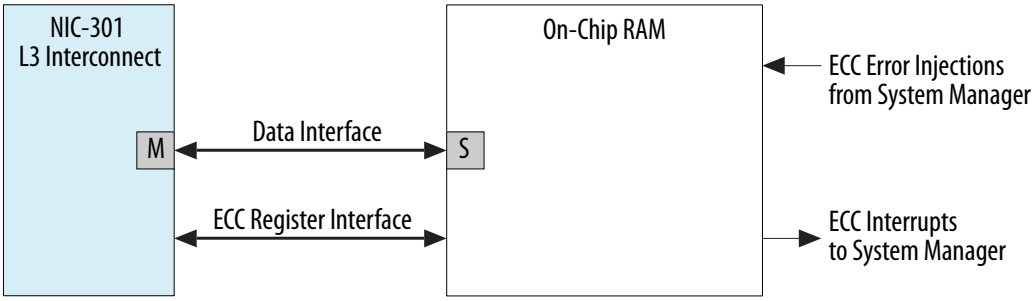
Clock Manager on page 2-1

On-Chip RAM Block Diagram and System Integration

Transfers between memory and the NIC-301 L3 interconnect happen through a 64-bit interface, gated by the `l3_main_clk` interconnect clock. ECC logic detects single-bit, corrected and double-bit, uncorrected errors. The memory has a read acceptance of two, a write acceptance of two, and a total acceptance of two with round-robin arbitration.

The entire RAM is either secure or non-secure. Security is enforced by the NIC-301 L3 interconnect.

Figure 12-1: On-Chip RAM Block Diagram



Note: You must initialize the on-chip RAM before you enable the ECC support to prevent false ECC interrupts triggered by uninitialized bits.

Functional Description of the On-Chip RAM

The on-chip RAM serves as a general-purpose memory accessible from the FPGA.

The on-chip RAM uses an 64-bit slave interface. The slave interface supports transfers between memory and the NIC-301 L3 interconnect. All reads and writes are serviced in order.

Related Information

Clock Manager on page 2-1

On-Chip RAM Clocks

The on-chip RAM is driven by the `l3_main_clk` interconnect clock.

The on-chip RAM uses an 64-bit slave interface. The slave interface supports transfers between memory and the NIC-301 L3 interconnect. All reads and writes are serviced in order.

On-Chip RAM Resets

The contents of the RAM remain unchanged on a cold or warm reset. Reset only clears the state associated with the slave interface.

On-Chip RAM Initialization

You must initialize the on-chip RAM before you enable the ECC. Failure to do so triggers spurious interrupts.

Initialize the on-chip RAM using the following steps:

- Disable ECC interrupts
- Enable ECC generation
- Initialize memory by clearing the contents by writing 0x0 in the address space
- Enable ECC interrupts

Related Information

On-Chip Memory Address Map and Register Definitions on page 12-4

Boot ROM

Features of the Boot ROM

The boot ROM offers the following features:

- 32-bit interface
- 64 KB size
- Single-ported ROM
- Read acceptance of two
- High throughput - read every clock cycle.

Related Information

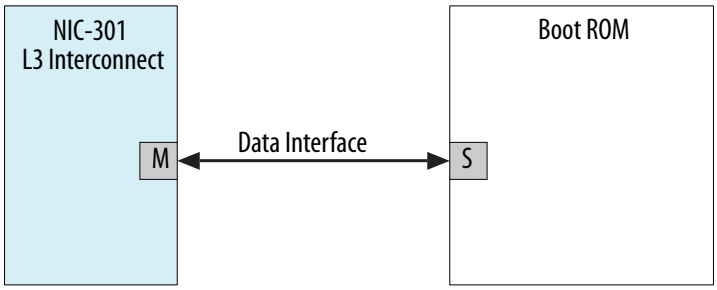
Clock Manager on page 2-1

Boot ROM Block Diagram and System Integration

Transfers between memory and the NIC-301 L3 interconnect happen through a 32-bit data interface, gated by the `l3_main_clk` interconnect clock.

The entire RAM is either secure or nonsecure. Security is enforced by the NIC-301 L3 interconnect.

Figure 12-2: Boot ROM Block Diagram



Functional Description of the Boot ROM

The boot ROM uses an 32-bit slave interface. The slave interface supports transfers between memory and the NIC-301 L3 interconnect. All writes return an error response.

NAND Flash Controller 13

2014.12.15

av_5v4 Subscribe Send Feedback

The hard processor system (HPS) provides a NAND flash controller to interface with external NAND flash memory in Altera® system-on-a-chip (SoC) FPGA systems. You can use external flash memory to store a processor boot image, software, or as extra storage capacity for large applications or user data. The HPS NAND flash controller is based on the Cadence® Design IP® NAND Flash Memory Controller.

NAND Flash Controller Features

The NAND flash controller provides the following functionality and features:

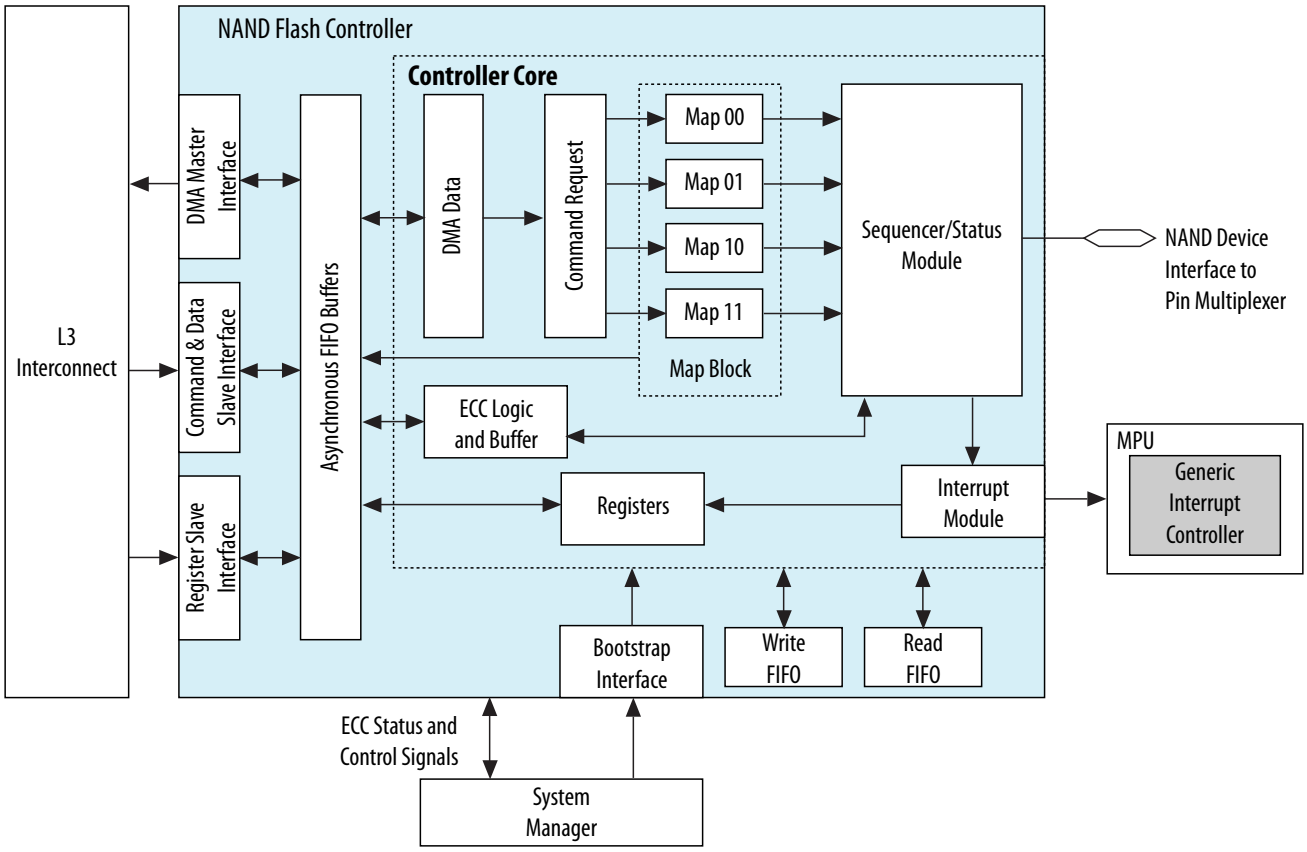
- Supports one x8 NAND flash device
- Supports Open NAND Flash Interface (ONFI) 1.0
- Supports NAND flash memories from Hynix, Samsung, Toshiba, Micron, STMicroelectronics, and Spansion

  Note: The Spansion S34ML08G2 NAND flash memory has been verified to work properly with the HPS.
- Supports error correction codes (ECCs) providing single-error correction and double-error detection:
  - With sector size programmable to 512 bytes (4-, 8-, or 16-bit correction) or 1024 bytes (24-bit correction)
  - With three NAND FIFOs - ECC Buffer, write FIFO and read FIFO
- Supports pipeline read-ahead and write commands for enhanced read/write throughput
- Supports devices with 32, 64, 128, 256, 384, or 512 pages per block
- Supports multiplane devices
- Supports page sizes of 512 bytes, 2 kilobytes (KB), 4 KB, or 8 KB
- Supports single-level cell (SLC) and multi-level cell (MLC) devices with programmable correction capabilities
- Provides internal direct memory access (DMA)
- Provides programmable access timing

NAND Flash Controller Block Diagram and System Integration

Figure 13-1: NAND Flash Controller Block Diagram

The following figure shows integration of the NAND flash controller in the HPS.



Features of the flash controller:

- Receives commands and data from the host through the command and data slave interface

  Note: The host accesses the flash controller's control and status registers (CSRs) through the register slave interface.
- Handles all command sequencing and flash device interactions

  Note: The bootstrap interface supports configuration of the NAND flash controller when booting the HPS from NAND flash memory.
- Generates interrupts to the HPS Cortex-A9 MPCore processor generic interrupt controller

  Note: The DMA master interface provides accesses to and from the flash controller through the controller's built-in DMA.

Functional Description of the NAND Flash Controller

This section describes the functionality of the NAND flash controller.

Discovery and Initialization

The NAND flash controller requires a specific initialization sequence after the HPS receives power and the flash device is stable. During initialization, the flash controller queries the flash device and configures itself according to one of the following flash device types:

- ONFI 1.0 compliant devices
- Legacy (non-ONFI) NAND devices

The NAND flash controller identifies ONFI-compliant connected devices using ONFI discovery protocol, by sending the `Read Electronic Signature` command. For devices that do not recognize this command (especially for 512-byte page size devices), software must write to the system manager to assert the `bootstrap_512B_device` signal to identify the device type before reset is de-asserted.

To support booting and initialization, the `rdy_busy_in` pin must be connected. The NAND flash controller sends the `reset` command to the connected device.

The NAND flash controller performs the following initialization steps:

1. If the system manager is asserting `bootstrap_inhibit_init`, the flash controller goes directly to step 7.
2. When the device is ready, the flash controller sends the `ONFI Read ID` command to read the ONFI signature from the memory device, to determine whether an ONFI or a legacy device is connected.
3. If the data returned by the memory device has an ONFI signature, the flash controller then reads the device parameter page. The flash controller stores the relevant device feature information in internal memory control registers, enabling it to correctly program other registers in the flash device, and goes to step 5.
4. If the data does not have a valid ONFI signature, the flash controller assumes that it is a legacy (non-ONFI) device. The flash controller then performs the following steps:
   a. Sends the `reset` command to the device
   b. Reads the device signature information
   c. Stores the relevant values into internal memory controller registers
5. The flash controller resets the memory device. At the same time, it verifies the width of the memory interface. The HPS supports one 8-bit NAND flash device. As a result, the flash controller always detects an 8-bit memory interface.
6. The flash controller sends the `Page Load` command to block 0, page 0 of the device, configuring direct read access, so the processor can boot from that page. The processor can start reading from the first page of the flash memory, which is the expected location of the pre-loader software.

   Note: The system manager can bypass this step by asserting `bootstrap_inhibit_b0p0_load` before reset is de-asserted.
7. The flash controller sends the `reset` command to the flash.
8. The flash controller sets the value of the `rst_comp` bit in the `intr_status0` register in the `status` group.

Bootstrap Interface

The NAND flash controller provides a bootstrap interface that allows software to override the default behavior of the flash controller. The bootstrap interface contains four bits, which when set appropriately, allows the flash controller to skip the initialization phase and begin loading from flash memory

immediately after reset. These bits are driven by software through the system manager. They are sampled by the NAND flash controller when the controller is released from reset.

Related Information

System Manager on page 5-1
For more information about the bootstrap interface control bits.

Bootstrap Setting Bits

The **Table 13-1** table lists the relevant bootstrap setting bits, found in the system manager's `bootstrap` register, in the `nandgrp` group. This table also lists recommended bootstrap settings for a 512-byte page device.

Table 13-1: Bootstrap Setting Bits

Register	Value
`noinit`	1[25]
`page512`	1
`noloadb0p0`	1
`tworowaddr`	• 1—flash device supports two-cycle addressing • 0—flash device support three-cycle addressing

Related Information

Configuration by Host on page 13-4

Configuration by Host

If the system manager sets `bootstrap_inhibit_init` to 1, the NAND flash controller does not perform the discovery and initialization process. In this case, the host processor must configure the flash controller.

When performance is not a concern in the design, the timing registers can be left unprogrammed.

Related Information

Bootstrap Setting Bits on page 13-4
For recommended configuration-by-host settings to enable the basic read, write, and erase operations for a single-plane, 512 bytes/page device.

[25] When this register is set, the NAND flash controller expects the host to program the related device parameter registers. For more information, refer to *Configuration by Host*.

Recommended Bootstrap Settings for 512-Byte Page Device

Table 13-2: Recommended Bootstrap Settings for 512-Byte Page Device

Register[26]	Value
devices_connected	1
device_width	0 indicating an 8-bit NAND flash device
number_of_planes	1 indicating a single-plane device
device_main_area_size	The value of this register must reflect the flash device's page main area size.
device_spare_area_size	The value of this register must reflect the flash device's page spare area size.
pages_per_block	The value of this register must reflect number of pages per block in the flash device.

NAND Page Main and Spare Areas

Each NAND page has a main area and a spare area. The main area is intended for data storage. The spare area is intended for ECC and maintenance data, such as wear leveling information. Each block consists of a group of pages.

The sizes of the main and spare areas, and the number of blocks in a page, depend on the specific NAND device connected to the NAND flash controller. Therefore, the device-dependent registers, device_main_area_size, device_spare_area_size, and pages_p er_block, must be programmed to match the characteristics of the device.

If your software does not perform the discovery and initialization sequence, the software must include an alternative method to determine the correct value of the device-dependent registers. The HPS boot ROM code enables discovery and initialization by default (that is, bootstrap_inhibit_init = 0).

Clocks

Table 13-3: Clock Inputs to NAND Flash Controller

Clock Signal	Description
nand_x_clk	Clock for master and slave interfaces and the ECC sector buffer
nand_clk	Clock for the NAND flash controller

The frequency of nand_x_clk is four times the frequency of nand_clk.

[26] All registers are in the config group.

Related Information

Clock Manager on page 2-1

Resets

The NAND flash controller has one reset signal, `nand_flash_rst_n`. The reset manager drives this signal to the NAND flash controller on a cold or warm reset.

When a tamper is detected, the reset manager sends a special signal to the NAND data RAM. This scrambles and clears the RAM. In addition, the RAM can be cleared during a cold or warm reset, depending on how fuse bits are programmed in the device.

Before the NAND flash controller comes out of the reset state, the pin multiplexers for the flash external interface must be configured.

Related Information

Reset Manager on page 3-1

Taking the NAND Flash Controller Out of Reset

When a cold or warm reset is issued in the HPS, the reset manager resets this module and holds it in reset until software releases it.

After the MPU boots up, it can deassert the reset signal by clearing the appropriate bits in the reset manager's corresponding reset register. For details about reset registers, refer to "Module Reset Signals".

Indexed Addressing

The NAND flash controller uses indexed addressing to reduce the address span consumed by the flash controller.

Indirect addressing is controlled by two registers, accessed through the command and data slave interface in the `nanddata` map, as described in *Register Map for Indexed Addressing*.

Register Map for Indexed Addressing

Table 13-4: Register Map for Indexed Addressing

Register Name	Offset Address	Usage
`Control`	0x0	Software writes the 32-bit control information consisting of MAP command type, block, and page address. The upper four bits must be set to 0. For specific usage of the `Control` register, refer to "MAP00 Address Mapping", "MAP01 Address Mapping", "MAP10 Address Mapping", and "MAP10 Operations".
`Data`	0x10	The `Data` register is a page-size window into the NAND flash. By reading from or writing to locations starting at this offset, the software reads directly from or writes directly to the page and block of NAND flash memory specified by the `Control` register.

Related Information

- **MAP00 Address Mapping** on page 13-8
- **MAP01 Address Mapping** on page 13-9
- **MAP10 Address Mapping** on page 13-10
- **MAP10 Operations** on page 13-10

Indexed Addressing Host Usage

The host uses indexed addressing as follows:

1. Program the 32-bit index-address field into the `Control` register at offset 0x0 of the data/command slave port. This action provides the flash address parameters to the NAND flash controller.
2. Perform a 32-bit read or write in the `Data` register at offset 0x10 of the data/command slave port.
3. Perform additional 32-bit reads and writes if they are in the same page and block in flash memory.

It is unnecessary to write to the control register for every data transfer if a group of data transfers targets the same page and block address. For example, you can write the control register at the beginning of a page with the block and page address, and then read or write the entire page by directing consecutive transactions to the `Data` register.

Command Mapping

The NAND flash controller supports several flash controller-specific MAP commands, providing an abstraction level for programming a NAND flash device. By using the MAP commands, you can avoid directly programming device-specific commands. Using this abstraction layer provides enhanced performance. Commands take multiple cycles to send off-chip. The MAP commands let you initiate commands and let the flash controller sequence them off-chip to the NAND device.

The NAND flash controller supports the following flash controller-specific MAP commands:

- MAP00 Commands—boot-read or buffer read/write during read-modify-write operations
- MAP01 Commands—memory arrays read/write
- MAP10 Commands—NAND flash controller commands
- MAP11 Commands—low-level direct access

Related Information

- **MAP00 Commands** on page 13-7
- **MAP01 Commands** on page 13-8
- **MAP10 Commands** on page 13-9
- **MAP11 Commands** on page 13-11

MAP00 Commands

MAP00 commands access a page buffer in the NAND flash device. Addressing always begins at 0x0 and extends to the page size specified by the `device_main_area_size` and `device_spare_area_size` registers in the `config` group. You can use this command to perform a boot read. Use MAP00 commands in read-modify-write (RMW) operations to read or write any word in the buffer. MAP00 commands allow a direct data path to the page buffer in the device.

The host can access the page buffer directly using the MAP00 commands only if there are no other MAP01 or MAP10 commands active on the NAND flash controller.

MAP00 Address Mapping

Table 13-5: MAP00 Address Mapping

Address Bits	Name	Description
31:28	(reserved)	Set to 0
27:26	CMD_MAP	Set to 0
25:13	(reserved)	Set to 0
12:2	BUFF_ADDR	Data width-aligned buffer address on the memory device. Maximum page access is 8 KB.
1:0	(reserved)	Set to 0

MAP00 Usage Limitations

The usage of this command under normal operations is limited to the following situations:

- It can be used to perform an Execute-in-Place (XIP) boot from the device; reading directly from the page buffer while booting directly from the device.
- MAP00 commands can be used to perform RMW operations where MAP00 writes are used to modify a read page in the device page buffer. Because the NAND flash controller does not perform ECC correction during such an operation, Altera does not recommend this method in an MLC device.
- In association with MAP11 commands, MAP00 commands provide a way for the host to directly access the device bypassing the hardware abstractions provided by NAND flash controller with MAP01 and MAP10 commands. This method is also used for debugging, or for issuing an operation that the flash controller might not support with MAP01 or MAP10 commands.

Restrictions:

- MAP00 commands cannot be used with MAP01 commands to read part of a page. Accesses using MAP01 commands must perform a complete page transfer.
- No ECC is performed during a MAP00 data access.
- DMA must be disabled (the `flag` bit of the `dma_enable` register in the `dma` group must be set to 0) while performing MAP00 operations.

MAP01 Commands

MAP01 commands transfer complete pages between the host memory and a specific page of the NAND flash device. Because the NAND flash controller supports only page addresses, the entire page must be read or written at once. The actual number of commands required depends on the size of the data transfer. You must use the same address until the entire page is transferred, even if multiple commands are required.

When the NAND flash controller receives a read command, it issues a load operation on the device, waits for the load to complete, and then returns read data. Read data must be read from the start of the page to the end of the page. Write data must be written from the start of the page to the end of the page.

When the NAND flash controller receives confirmation of the transfer, it issues commands to program the data into the device. The flash controller ignores the byte enables for read and write commands and transfers the entire data width.

MAP01 Address Mapping

Table 13-6: MAP01 Address Mapping

Address Bits	Name	Description
31:28	(reserved)	Set to 0
27:26	CMD_MAP	Set to 1
25:24	(reserved)	Set to 0
23:<*M*> (27)	BLK_ADDR	Block address in the device
(<*M*>-1):0 (27)	PAGE_ADDR	Page address in the device

MAP01 Command Usage

Use the MAP01 command as follows:

- A complete page must be read or written using a MAP01 command. During such transfers, every transaction from the host must have the same block and page address. The NAND flash controller internally keeps track of how much of data it reads or writes.
- MAP00 commands cannot be used in between using MAP01 commands for reading or writing a page.
- DMA must be disabled (the `flag` bit of the `dma_enable` register in the `dma` group must be set to 0) while the host is performing MAP01 operations directly. If the host issues MAP01 commands to the NAND flash controller while DMA is enabled, the flash controller discards the request and generates an `unsup_cmd` interrupt.

MAP10 Commands

MAP10 commands provide an interface to the control plane of the NAND flash controller. MAP10 commands control special functions of the flash device, such as erase, lock, unlock, copy back, and page spare area access. Data passed in this command pathway targets the NAND flash controller rather than the flash device. Unlike other command types, the data (input or output) related to these transactions does not affect the contents of the flash device. Rather, this data specifies and performs the exact commands of the flash controller. Only the lower 16 bits of the `Data` register contain the relevant information.

(27) <*M*> depends on the number of pages per block in the device. <*M*> = ceil(log2(<*device pages per block*>)) . Therefore, use the following values:

32 pages per block: <*M*>=5

64 pages per block: <*M*>=6

128 pages per block: <*M*>=7

256 pages per block: <*M*>=8

384 pages per block: <*M*>=9

512 pages per block: <*M*>=9

MAP10 Address Mapping

Table 13-7: MAP10 Address Mapping

Address Bits	Name	Description
31:28	(reserved)	Set to 0
27:26	CMD_MAP	Set to 2
25:24	(reserved)	Set to 0
23:<M>[28]	BLK_ADDR	Block address in the device
(<M>-1):0[28]	PAGE_ADDR	Page address in the device

MAP10 Operations

Table 13-8: MAP10 Operations

Command	Function
0x01	Sets block address for erase and initiates operation
0x10	Sets unlock start address
0x11	Sets unlock end address and initiates unlock
0x21	Initiates a lock of all blocks
0x31	Initiates a lock-tight of all blocks
0x41	Sets up for spare area access

[28] <*M*> depends on the number of pages per block in the device. <*M*> = ceil(log2(<*device pages per block*>)) . Therefore, use the following values:

32 pages per block: <*M*>=5

64 pages per block: <*M*>=6

128 pages per block: <*M*>=7

256 pages per block: <*M*>=8

384 pages per block: <*M*>=9

512 pages per block: <*M*>=9

Command	Function
0x42	Sets up for default area access
0x43	Sets up for main+spare area access
0x60	Loads page to the buffer for a RMW operation
0x61	Sets the destination address for the page buffer in RMW operation
0x62	Writes the page buffer for a RMW operation
0x1000	Sets copy source address
0x11<*PP*>	Sets copy destination address and initiates a copy of <*PP*> pages
0x20<*PP*>	Sets up a pipeline read-ahead of <*PP*> pages
0x21<*PP*>	Sets up a pipeline write of <*PP*> pages

MAP10 Command Usage

Use the MAP10 command as follows:

- MAP10 commands should be used to issue commands to the device, such as erase, copy-back, lock, or unlock.
- MAP10 pipeline commands should also be used to read or write consecutive multiple pages from the flash device within a device block boundary. The host must first issue a MAP10 pipeline read or write command and then issue MAP01 commands to do the actual data transfers. The MAP10 pipeline read or write command instructs the NAND flash controller to use high-performance commands such as cache or multiplane because the flash controller has knowledge of multiple consecutive pages to be read. The pages must not cross a block boundary. If a block boundary is crossed, the flash controller generates an unsupported command (`unsup_cmd`) interrupt and drops the command.
- Up to four pipeline read or write commands can be issued to the NAND flash controller.
- While the NAND flash controller is performing MAP10 pipeline read or write commands, DMA must be disabled (the `flag` bit of the `dma_enable` register in the `dma` group must be set to 0). DMA must be disabled because the host is directly transferring data from and to the flash device through the flash controller.

MAP11 Commands

MAP11 commands provide direct access to the NAND flash controller's address and control cycles, allowing software to issue the commands directly to the flash device using the `Command` and `Data` registers. The MAP11 command is useful if the flash device supports a device-specific command not supported by standard flash commands. It can also be useful for low-level debugging.

MAP11 commands provide a direct control path to the flash device. These commands execute command, address, and data read/write cycles directly on the NAND device interface. Command, address, and write data values are placed in the `Data` register. On a read, the returned data also appears in the `Data` register. The indirect address register encodes the control operation type. Command and address cycles to the device must be a write transaction on the host bus. For data cycles, the type of transaction on the host bus

(read/write) determines the data cycle type on the device interface. The host can issue only single-beat accesses to the data slave port while using MAP11 commands.

MAP11 Addressing Mapping

Table 13-9: MAP11 Addressing Mapping

Address Bits	Name	Description
31:28	(reserved)	Set to 0
27:26	CMD_MAP	Set to 3
25:2	(reserved)	Set to 0
1:0	TYPE	Sets the control type as follows: • 0 = Command cycle • 1 = Address cycle • 2 = Data Read/Write Cycle

MAP11 Command Usage

Use the MAP11 command as follows:

- Use MAP11 commands only in special cases, for debugging or sending device-specific commands that are not supported by the NAND flash controller.
- DMA must be disabled before you use MAP11 operations.
- The host can use only single beat access transfers when using MAP11 commands.

Note: MAP11 commands provide direct, unstructured access to the NAND flash device. Incorrect use can lead to unpredictable behavior.

Data DMA

The DMA transfers data with minimal host involvement. Software initiates data DMA with the MAP10 command.

The `flag` bit of the `dma_enable` register in the `dma` group enables data DMA functionality. Only enable or disable this functionality when there are no active transactions pending in the NAND flash controller. When the DMA is enabled, the flash controller initiates one DMA transfer per MAP10 command over the DMA master interface. When the DMA is disabled, all operations with the flash controller occur through the data/command slave interface.
